- Purpose** Return the appropriate byte position for truncating a text buffer such that it is at most a specified number of bytes long.
- Declared In** `TextMgr.h`
- Prototype** `UInt32 TxtGetTruncationOffset (const Char* inText, UInt32 inOffset)`
- Parameters**
- > `inText`            Pointer to a text buffer.
  - > `inOffset`          An offset into the buffer `inText`.
- Result** Returns the appropriate byte offset for truncating `inText` at a valid inter-character boundary. The return value may be less than or equal to `inOffset`.
- Comments** You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.
- Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetTruncationOffset`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## **TxtGetWordWrapOffset**

- Purpose** Locate an appropriate place for a line break in a text buffer.
- Declared In** `TextMgr.h`
- Prototype** `UInt32 TxtGetWordWrapOffset (const Char *iTextP, UInt32 iOffset)`
- Parameters**
- > `iTextP`            Pointer to a text buffer.

## Text Manager

### Text Manager Functions

---

-> `iOffset`      Pointer to the offset where the search should begin. The search is performed backward starting from this offset.

**Result**      Returns the offset of a character that can begin on a new line (typically, the beginning of the word that contains `iOffset` or last word before `iOffset`). If an appropriate break could not be found, returns `iOffset`.

**Comments**      The [FntWordWrap](#) and [FntWordWrapReverseNLines](#) functions call `TxtGetWordWrapOffset` to locate an appropriate place to break the text. The returned offset points to the character that should begin the next line.

This function starts at `iOffset` and works backward until it finds a character that typically occurs between words (for example, white space or punctuation). Then it moves forward until it locates the character that begins a word (typically, a letter or number). Note that this function may return an offset value that is greater than the one passed in if the offset passed in occurs immediately before white space or in the middle of white space.

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

**See Also**      [TxtWordBounds](#)

## TxtMaxEncoding

**Purpose**      Return the higher of two encodings.

**Declared In**      `TextMgr.h`

**Prototype**      `CharEncodingType TxtMaxEncoding`  
`(CharEncodingType a, CharEncodingType b)`

**Parameters**      -> `a`      A character encoding to compare.

-> b                      Another character encoding to compare.

**Result**            Returns the higher of a or b. One character encoding is higher than another if it is more specific. For example code page 1252 is “higher” than ISO 8859-1 because it represents more characters than ISO 8859-1.

**Comments**        This function is used by [TxtStrEncoding](#) to determine the encoding required for a string.

**Compatibility**    Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueMaxEncoding`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also**         [TxtCharEncoding](#), [CharEncodingType](#)

## **TxtNameToEncoding**

**Purpose**            Return an encoding’s constant given its name.

**Declared In**      `TextMgr.h`

**Prototype**        `CharEncodingType TxtNameToEncoding  
(const Char *iEncodingName)`

**Parameters**      -> `iEncodingName`  
                         One of the string constants containing the official name of an encoding. See [TxtEncodingName](#) for a list.

**Result**            Returns one of the [Character Encoding Constants](#). Returns `charEncodingUnknown` if the specified encoding could not be found.

**Comments**        Use this function to convert a character encoding’s name as received from an Internet application into the character encoding constant that some text manager functions require.

## Text Manager

### Text Manager Functions

---

This function properly converts aliases for a character encoding. For example, passing the strings “us-ascii”, “ASCII”, “cp367”, and “IBM367” all return `charEncodingAscii`.

The known character encodings are device-dependent. For example, a device with the Shift-JIS encoding will not know all of the aliases for Latin character encodings; however, it will know all of the aliases for Shift-JIS.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TxtEncodingName](#)

## TxtNextCharSize

**Purpose** Macro that returns the size of the character starting at the specified offset within a text buffer.

**Declared In** `TxtMgr.h`

**Prototype** `TxtNextCharSize (inText, inOffset)`

**Parameters**

- > `inText` Pointer to the text buffer to be searched.
- > `inOffset` A valid offset into the buffer `inText`. This offset must point to an inter-character boundary.

**Result** Returns (as a `UInt16`) the size in bytes of the character at `inOffset`.

**Comments** You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with

the PalmOSGlue library and call `TxtGlueNextCharSize`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtGetNextChar](#)

## **TxtParamString**

**Purpose** Replace substrings within a string with the specified values.

**Declared In** `TextMgr.h`

**Prototype** `Char* TxtParamString (const Char* inTemplate, const Char* param0, const Char* param1, const Char* param2, const Char* param3)`

**Parameters**

|                            |                                                               |
|----------------------------|---------------------------------------------------------------|
| -> <code>inTemplate</code> | The string containing the substrings to replace.              |
| -> <code>param0</code>     | String to replace <code>^0</code> with or <code>NULL</code> . |
| -> <code>param1</code>     | String to replace <code>^1</code> with or <code>NULL</code> . |
| -> <code>param2</code>     | String to replace <code>^2</code> with or <code>NULL</code> . |
| -> <code>param3</code>     | String to replace <code>^3</code> with or <code>NULL</code> . |

**Result** Returns a pointer to a locked relocatable chunk in the dynamic heap that contains the appropriate substitutions.

**Comments** This function searches `inTemplate` for occurrences of the sequences `^0`, `^1`, `^2`, and `^3`. When it finds these, it replaces them with the corresponding string passed to this function. Multiple instances of each sequence will be replaced.

The replacement strings can also contain the substitution strings, provided they refer to a later parameter. That is, the `param0` string contain have references to `^1`, `^2`, and `^3`, the `param1` string can have references to `^2` and `^3`, and the `param2` string can have references to `^3`. Any other occurrences of the substitution strings in the replacement strings are ignored. For example, if `param3` is the string `“^0”`, any occurrences of `^3` in `inTemplate` are replaced with the string `“^0”`.

## Text Manager

### Text Manager Functions

---

You must make sure that the parameter `inTemplate` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

`TxtParamString` allocates space for the returned string in the dynamic heap through a call to `MemHandleNew`, and then returns the result of calling `MemHandleLock` with this handle. Your code is responsible for freeing this memory when it is no longer needed.

**Compatibility** Implemented if [3.5 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueParamString`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtReplaceStr](#), [FrmCustomAlert](#)

## TxtPreviousCharSize

**Purpose** Macro that returns the size of the character before the specified offset within a text buffer.

**Declared In** `TxtMgr.h`

**Prototype** `TxtPreviousCharSize (inText, inOffset)`

**Parameters**

- > `inText` Pointer to the text buffer.
- > `inOffset` A valid offset into the buffer `inText`. This offset must point to an inter-character boundary.

**Result** Returns (as a `UInt16`) the size in bytes of the character preceding `inOffset` in `inText`. Returns 0 if `inOffset` is at the start of the buffer (that is, `inOffset` is 0).

**Comments** You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

This macro is often slower to use than [TxtNextCharSize](#) because it must determine the appropriate character boundaries if the byte immediately before the offset is valid in more than one location (start, middle, or end) of a multi-byte character. To do this, it must work backwards toward the beginning of the string until it finds an unambiguous byte.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGluePreviousCharSize`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetPreviousChar](#)

## TxtReplaceStr

**Purpose** Replace a substring of a given format with another string.

**Declared In** `TextMgr.h`

**Prototype**

```
UInt16 TxtReplaceStr (Char* ioStr,
UInt16 inMaxLen, const Char* inParamStr,
UInt16 inParamNum)
```

**Parameters**

|                               |                                                                                                               |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; ioStr</code>  | The string in which to perform the replacing.                                                                 |
| <code>-&gt; inMaxLen</code>   | The maximum length in bytes that <code>ioStr</code> can become.                                               |
| <code>-&gt; inParamStr</code> | The string that <code>^inParamNum</code> should be replaced with. If <code>NULL</code> , no changes are made. |
| <code>-&gt; inParamNum</code> | A single-digit number (0 to 9).                                                                               |

**Result** Returns the number of occurrences found and replaced.  
Returns a fatal error message if `inParamNum` is greater than 9.

**Comments** This function searches `ioStr` for occurrences of the string `^inParamNum`, where `inParamNum` is any digit from 0 to 9. When it finds the string, it replaces it with `inParamStr`. Multiple instances

## Text Manager

### Text Manager Functions

---

will be replaced as long as the resulting string doesn't contain more than `inMaxLen` bytes, not counting the terminating null.

You can set the `inParamStr` parameter to `NULL` to determine the required length of `ioStr` before actually doing the replacing. `TxtReplaceStr` returns the number of occurrences it finds of `^inParamNum`. Multiply this value by the length of the `inParamStr` you intend to use to determine the appropriate length of `ioStr`.

You must make sure that the parameter `ioStr` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueReplaceStr`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## TxtSetNextChar

**Purpose** Set a character within a text buffer.

**Declared In** `TextMgr.h`

**Prototype** `UInt16 TxtSetNextChar (Char* ioText, UInt32 inOffset, WChar inChar)`

**Parameters**

|                               |                                                                                                             |
|-------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; ioText</code> | Pointer to a text buffer.                                                                                   |
| <code>-&gt; inOffset</code>   | A valid offset into the buffer <code>inText</code> . This offset must point to an inter-character boundary. |
| <code>-&gt; inChar</code>     | The character to replace the character at <code>inOffset</code> with. Must not be a virtual character.      |

**Result** Returns the size of `inChar`.

**Comments** This function replaces the character in `ioText` at the location `inOffset` with the character `inChar`. Note that there must be enough space at `inOffset` to write the character.

You can use [TxtCharSize](#) to determine the size of `inChar`.

You must make sure that the parameter `ioText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueSetNextChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetNextChar](#)

## **TxtStrEncoding**

**Purpose** Return the encoding required to represent a string.

**Declared In** `TextMgr.h`

**Prototype** `CharEncodingType TxtStrEncoding  
(const Char* inStr)`

**Parameters** `-> inStr` A string.

**Result** A [CharEncodingType](#) value that indicates the encoding required to represent `inChar`. If any character in the string isn't recognizable, then `charEncodingUnknown` is returned.

**Comments** The encoding for the string is the maximum encoding of any character in that string. For example, if a two-character string contains a blank space and a ü, the appropriate encoding is `charEncodingISO8859_1`. The blank space's minimum encoding is ASCII. The minimum encoding for the ü is ISO 8859-1. The maximum of these two encodings is ISO 8859-1.

## Text Manager

### Text Manager Functions

---

Because Palm OS only supports a single character encoding at a time, the results of this function is always logically equal to or less than the encoding used on the current system. That is, you'll only receive a return value of `charEncodingISO8859_1` if you're running on a Latin-based system.

Use this function for informational purposes only. Your code should not assume that the character encoding returned by this function is the Palm OS system's character encoding. (Instead use `FtrGet` as shown in the [TxtCharXAttr](#) function description.)

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueStrEncoding`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtCharEncoding](#), [TxtMaxEncoding](#)

## TxtTransliterate

**Purpose** Converts the specified number of bytes in a text buffer using the specified operation.

**Declared In** `TextMgr.h`

**Prototype** `Err TxtTransliterate (const Char* inSrcText, UInt16 inSrcLength, Char* outDstText, UInt16* ioDstLength, TranslitOpType inOp)`

**Parameters**

- > `inSrcText` Pointer to a text buffer.
- > `inSrcLength` The length in bytes of `inSrcText`.
- <- `outDstText` The output buffer containing the converted characters.
- <-> `ioDstLength` Upon entry, the maximum length of `outDstText`. Upon return, the actual length of `outDstText`.

-> `inOp`      A 16-bit unsigned value that specifies which transliteration operation is to be performed. The values possible for this field are specific to the character encoding used on a particular device. These operations are universally available:

- `translitOpUpperCase`  
Converts the character to uppercase letters.
- `translitOpLowerCase`  
Converts the characters to lowercase letters.
- `translitOpPreprocess`  
Don't actually perform the operation. Instead, return in `ioDstLength` the amount of space required for the output text.

**Result**      Returns one of the following values:

- `errNone`      Success
- `txtErrUnknownTranslitOp`  
    `inOp`'s value is not recognized
- `txtErrTranslitOverrun`  
    `inSrcText` and `outDstText` point to the same memory location and the operation has caused the function to overwrite unprocessed data in the input buffer.
- `txtErrTranslitOverflow`  
    `outDstText` is not large enough to contain the converted string.
- `txtErrTranslitUnderflow`  
    The end of the source buffer contains a partial character.

**Comments**      `inSrcText` and `outDstText` may point to the same location if you want to perform the operation in place. However, you should

## Text Manager

### Text Manager Functions

---

be careful that the space required for `outDstText` is not larger than `inSrcText` so that you don't generate a `txtErrTranslitOverrun` error.

For example, suppose on a Shift JIS encoded system, you want to convert a series of single-byte Japanese Katakana symbols to double-byte Katakana symbols. You cannot perform this operation in place because it replaces a single-byte character with a multi-byte character. When the first converted character is written to the buffer, it overwrites the second input character. Thus, a text overrun has occurred.

You can ensure that you have enough space for the output by OR-ing your chosen operation with `translitOpPreprocess`. For example, to convert a string to uppercase letters, do the following:

```
outSize = buf2Len;
error = TxtTransliterate(buf1, buf1Len, &buf2,
    &outSize,
    translitOpUpperCase|translitOpPreprocess);
if (outSize > buf2Len)
    /* allocate more memory for buf2 */
    error = TxtTransliterate(buf1, buf1Len, &buf2,
    &outSize, translitOpUpperCase);
```

You must make sure that the parameter `inSrcText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueTransliterate`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

In Palm OS 4.0, the `TxtTransliterate` function terminates when it finds a null byte in the source string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameter.

## TxtWordBounds

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |           |                           |             |                                                       |             |                                                                                                     |             |                                       |           |                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---------------------------|-------------|-------------------------------------------------------|-------------|-----------------------------------------------------------------------------------------------------|-------------|---------------------------------------|-----------|-------------------------------------|
| <b>Purpose</b>       | Find the boundaries of a word of text that contains the character starting at the specified offset.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |           |                           |             |                                                       |             |                                                                                                     |             |                                       |           |                                     |

| <b>Result</b>        | Returns true if a word is found. Returns false if the word doesn't exist or is punctuation or whitespace.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |           |                           |             |                                                       |             |                                                                                                     |             |                                       |           |                                     |
| <b>Comments</b>      | <p>Assuming the ASCII encoding, if the text buffer contains the string "Hi! How are you?" and you pass 5 as the offset, TxtWordBounds returns the start and end of the word containing the character at offset 5, which is the character "o". Thus, outStart and outEnd would point to the start and end of the word "How".</p> <p>You must make sure that the parameter inText points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.</p> |           |                           |             |                                                       |             |                                                                                                     |             |                                       |           |                                     |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueWordBounds. For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                                                                                                      |           |                           |             |                                                       |             |                                                                                                     |             |                                       |           |                                     |

## Text Manager

### *Text Manager Functions*

---

In Palm OS 4.0, the `TxtWordBounds` function terminates when it finds a null byte in the string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameter.

**See Also** [TxtCharBounds](#), [TxtCharIsDelim](#), [TxtGetWordWrapOffset](#)

# Text Services Manager

---

This chapter provides information about the Text Services Manager API as declared in `TextServicesMgr.h`. The Text Services Manager provides the caller with an API for interacting with various text services, including front-end processors (FEPs), which are sometimes known as input methods. This chapter discusses the following topics:

- [Text Services Manager Data Structures](#)
- [Text Services Manager Functions](#)

## Text Services Manager Data Structures

### TsmFepModeType

The `TsmFepModeType` type specifies the input modes used by the functions [TsmGetFepMode](#) and [TsmSetFepMode](#).

```
typedef UInt16 TsmFepModeType;
```

`TsmFepModeType` can be set to one of the defined modes listed in the following table.

| Constant                       | Value | Description                                                                                           |
|--------------------------------|-------|-------------------------------------------------------------------------------------------------------|
| <code>tsmFepModeDefault</code> | 0     | The default input mode for the FEP. For example, with the Japanese FEP, the default mode is Hiragana. |

## Text Services Manager

### Text Services Manager Functions

---

| Constant                      | Value | Description                                                                                                                                                     |
|-------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tsmFepModeOff</code>    | 1     | Indicates that there is no active FEP input mode (the FEP is off).                                                                                              |
| <code>tsmFepModeCustom</code> | 128   | A custom FEP input mode. You can have more than one custom mode; the starting value is 128. Katagana is an example of a custom input mode for the Japanese FEP. |

---

## Text Services Manager Functions

### TsmGetFepMode

|                      |                                                                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the current input mode for the active front-end processor (FEP).                                                                                                                                                                                     |
| <b>Declared In</b>   | <code>TextServicesMgr.h</code>                                                                                                                                                                                                                              |
| <b>Prototype</b>     | <code>TsmFepModeType TsmGetFepMode (void *nullParam)</code>                                                                                                                                                                                                 |
| <b>Parameters</b>    | <code>-&gt; nullParam</code> An unused status pointer that must be set to <code>NULL</code> .                                                                                                                                                               |
| <b>Result</b>        | If there is an active FEP, returns the current mode for the active FEP. If there is no active FEP, returns <code>tsmFepModeOff</code> .                                                                                                                     |
| <b>Comments</b>      | The most common use for this function is to save the current FEP mode. You could then call <a href="#">TsmSetFepMode</a> to set the current mode to “off” and again to restore the saved mode once the application has finished using a special text field. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present. In Palm OS 3.5, the <code>nullParam</code> parameter takes a non- <code>NULL</code> value, allowing the caller to maintain its own status record. In Palm OS 4.0, this                  |

parameter is unused and must be set to NULL. Any other value generates a non-fatal alert.

**See Also** [TsmSetFepMode](#)

## TsmSetFepMode

**Purpose** Set the input mode for the active front-end processor (FEP) to be the mode defined by the parameter `inNewMode`.

**Declared In** `TextServicesMgr.h`

**Prototype** `TsmFepModeType TsmSetFepMode (void *nullParam, TsmFepModeType inNewMode)`

**Parameters**

- > `nullParam` An unused status pointer that must be set to NULL.
- > `inNewMode` The new FEP input mode.

**Result** Returns the previous input mode. If there is no active FEP, returns `tsmFepModeOff`.

**Comments** The most common use for this function is to set the FEP mode to “off” while the application is using a special text field, and then to restore the previous mode. See [TsmGetFepMode](#) for more information on saving and restoring the FEP mode.

One common reason for explicitly disabling the FEP in code is when a text field will only contain 7-bit ASCII (numeric fields automatically turn off the FEP). For example, if the application has a password field and the contents of that field will always be 7-bit ASCII, the application should turn off the FEP to help prevent the user from entering invalid characters into the field.

Another common case occurs when the application has a numeric field, but cannot just rely on the numeric field attribute. For example, if you want the user to be able to enter the minus (“-”) sign, you cannot use a numeric field because the field code prevents the user from entering this character: its not a digit or a period. In this case, you should make it a regular field and have the

## Text Services Manager

### *Text Services Manager Functions*

---

application screen the characters. The application should disable the FEP when such a pseudo-numeric field is active.

---

**IMPORTANT:** A mode change is currently enqueued as a keyDown event so that the field and FEP can remain properly synchronized and so that the mode change doesn't affect any pending keyDown events. The mode change does not happen until the enqueued keyDown event is passed to `FrmHandleEvent`; if you call [TsmGetFepMode](#) immediately after calling [TsmSetFepMode](#), you won't see a mode change.

There are also some current limitations with changing the mode: there must be an active form; and if there is an active field in the form, it must not be a numeric field.

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. In Palm OS 3.5, the `nullParam` parameter takes a non-NULL value, allowing the caller to maintain its own status record. In Palm OS 4.0, this parameter is unused and must be set to NULL. Any other value generates a non-fatal alert.

**See Also** [TsmGetFepMode](#), [EvtEnqueueKey](#), [FrmHandleEvent](#)

# Time Manager

---

This chapter provides reference material for the time manager.

- [Time Manager Data Structures](#)
- [Time Manager Functions](#)

The header file `DateTime.h` declares the API that this chapter describes. For more information on the time manager, see the section “[Time](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Time Manager Data Structures

The time manager uses these structures to store information.

### DateFormatType

The `DateFormatType` enum specifies the different display formats for date values.

```
typedef enum {
    dfMDYWithSlashes,
    dfDMYWithSlashes,
    dfDMYWithDots,
    dfDMYWithDashes,
    dfYMDWithSlashes,
    dfYMDWithDots,
    dfYMDWithDashes,
    dfMDYLongWithComma,
    dfDMYLong,
    dfDMYLongWithDot,
    dfDMYLongNoDay,
    dfDMYLongWithComma,
    dfYMDLongWithDot,
    dfYMDLongWithSpace,
    dfMYMed,
    dfMYMedNoPost,
```

## Time Manager

### Time Manager Data Structures

---

```
    dfMDYWithDashes  
} DateFormatType;
```

#### Value Descriptions

`dfMDYWithSlashes` The month, day, and year numbers separated by slashes. For example, 12/31/95.

This is considered a short format.

`dfDMYWithSlashes` The day, month, and year numbers separated by slashes. For example, 31/12/95.

This is considered a short format.

`dfDMYWithDots` The day, month, and year numbers separated by dots. For example, 31.12.95.

This is considered a short format.

`dfDMYWithDashes` The day, month, and year numbers separated by dashes. For example, 31-12-95.

This is considered a short format.

`dfYMDWithSlashes` The year, month, and day numbers separated by slashes. For example, 95/12/31.

This is considered a short format.

`dfYMDWithDots` The year, month, and day numbers separated by dots. For example, 95.12.31.

This is considered a short format.

|                                 |                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>dfYMDWithDashes</code>    | <p>The year, month, and day numbers separated by dashes. For example, 95-12-31.</p> <p>This is considered a short format.</p>         |
| <code>dfMDYLongWithComma</code> | <p>The month, day, and year in long format, with a comma. For example, Dec 31, 1995.</p> <p>This is considered a long format.</p>     |
| <code>dfDMYLong</code>          | <p>The month, day, and year in long format. For example, 31 Dec 1995.</p> <p>This is considered a long format.</p>                    |
| <code>dfDMYLongWithDot</code>   | <p>The month, day, and year in long format, with a dot. For example, 31. Dec 1995.</p> <p>This is considered a long format.</p>       |
| <code>dfDMYLongNoDay</code>     | <p>The month and year in long format. For example, Dec 1995.</p> <p>This is considered a long format.</p>                             |
| <code>dfDMYLongWithComma</code> | <p>The day, month, and year in long format, with a comma. For example, 31 Dec, 1995.</p> <p>This is considered a long format.</p>     |
| <code>dfYMDLongWithDot</code>   | <p>The year, month, and day in long format with dot separators. For example, 1995.12.31.</p> <p>This is considered a long format.</p> |

## Time Manager

### Time Manager Data Structures

---

|                                 |                                                                                                                                               |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dfYMDLongWithSpace</code> | The year, month, and day in long format with space separators. For example, 1995 Dec 31.<br><br>This is considered a long format.             |
| <code>dfMYMed</code>            | The month in long format with the two-digit year, preceded by an apostrophe. For example, Dec '95.<br><br>This is considered a medium format. |
| <code>dfMYMedNoPost</code>      | The month in long format with the two-digit year. For example, Dec 95.<br><br>This is considered a medium format.                             |
| <code>dfMDYWithDashes</code>    | The month, day, and year numbers separated by dashes. For example, 12-31-95.<br><br>This is considered a short format.                        |

**Compatibility** The `dfMDYWithDashes` constant is defined in Palm OS® 4.0 and higher.

## DateTimeType

The `DateTimeType` structure represents a date and time value.

```
typedef struct {
    Int16    second;
    Int16    minute;
    Int16    hour;
    Int16    day;
    Int16    month;
    Int16    year;
    Int16    weekDay;
} DateTimeType
typedef DateTimeType *DateTimePtr;
```

### Field Descriptions

|         |                                                                                                      |
|---------|------------------------------------------------------------------------------------------------------|
| second  | The number of seconds. This is a value between 0 and 59.                                             |
| minute  | The number of minutes. This is a value between 0 and 59.                                             |
| hour    | The number of hours. This is a value between 0 and 23.                                               |
| day     | The day number. This is a value between 1 and 31.                                                    |
| month   | The month number. This is a value between 1 and 12.                                                  |
| year    | The year number.                                                                                     |
| weekDay | The day number. This represents the number of days since Sunday and is thus a value between 0 and 6. |

### DateType

The `DateType` structure represents a date value.

```
typedef struct{
    UInt16 year    :7;
    UInt16 month   :4;
    UInt16 day     :5;
} DateType;

typedef DateType *DatePtr;
```

### Field Descriptions

|       |                                                           |
|-------|-----------------------------------------------------------|
| year  | The number of years since 1904.                           |
|       | Note that this is the format used on Macintosh computers. |
| month | The month number. This is a value between 1 and 12.       |
| day   | The day number. This is a value between 1 and 31.         |

### DaylightSavingsTypes

The `DaylightSavingsTypes` enum specifies the different forms of daylight savings times that you can specify for date and time values.

## Time Manager

### Time Manager Data Structures

---

Note that the table uses “DST” to represent daylight savings time.

```
typedef enum {
    dsNone,
    dsUSA,
    dsAustralia,
    dsWesternEuropean,
    dsMiddleEuropean,
    dsEasternEuropean,
    dsGreatBritain,
    dsRumania,
    dsTurkey,
    dsAustraliaShifted
} DaylightSavingsTypes;
```

#### Value Descriptions

|                    |                                     |
|--------------------|-------------------------------------|
| dsNone             | No DST (daylight savings time)      |
| dsUSA              | U.S.A. DST                          |
| dsAustralia        | Australian DST                      |
| dsWesternEuropean  | Western European DST                |
| dsMiddleEuropean   | Middle European DST                 |
| dsEasternEuropean  | Eastern European DST                |
| dsGreatBritain     | Great Britain and Eire DST          |
| dsRumania          | Rumanian DST                        |
| dsTurkey           | Turkish DST                         |
| dsAustraliaShifted | Australian DST, with the 1986 shift |

#### Compatibility

If [4.0 New Feature Set](#) is present, this data type is obsolete. In versions 4.0 and higher, Palm OS represents daylight savings time as an integer value that gives the number of minutes to add to the current time for daylight savings time.

## DayOfMonthType

The `DayOfMonth` enum specifies the different day-of-the-week numeric values that are returned by the [DayOfMonth](#) function. These values are used to represent repeating appointments that occur on specific days of the month; for example, the first Friday or the third Tuesday of each month.

```
typedef enum {
    dom1stSun, dom1stMon, dom1stTue, dom1stWen,
    dom1stThu, dom1stFri, dom1stSat,
    dom2ndSun, dom2ndMon, dom2ndTue, dom2ndWen,
    dom2ndThu, dom2ndFri, dom2ndSat,
    dom3rdSun, dom3rdMon, dom3rdTue, dom3rdWen,
    dom3rdThu, dom3rdFri, dom3rdSat,
    dom4thSun, dom4thMon, dom4thTue, dom4thWen,
    dom4thThu, dom4thFri, dom4thSat,
    domLastSun, domLastMon, domLastTue,
    domLastWen, domLastThu, domLastFri,
    domLastSat
} DayOfWeekType;
```

### Value Descriptions

|                        |                                    |
|------------------------|------------------------------------|
| <code>dom1stSun</code> | The first Sunday of the month.     |
| <code>dom1stMon</code> | The first Monday of the month.     |
| <code>dom1stTue</code> | The first Tuesday of the month.    |
| <code>dom1stWen</code> | The first Wednesday of the month.  |
| <code>dom1stThu</code> | The first Thursday of the month.   |
| <code>dom1stFri</code> | The first Friday of the month.     |
| <code>dom1stSat</code> | The first Saturday of the month.   |
| <code>dom2ndSun</code> | The second Sunday of the month.    |
| <code>dom2ndMon</code> | The second Monday of the month.    |
| <code>dom2ndTue</code> | The second Tuesday of the month.   |
| <code>dom2ndWen</code> | The second Wednesday of the month. |

## Time Manager

### *Time Manager Data Structures*

---

|            |                                    |
|------------|------------------------------------|
| dom2ndThu  | The second Thursday of the month.  |
| dom2ndFri  | The second Friday of the month.    |
| dom2ndSat  | The second Saturday of the month.  |
| dom3rdSun  | The third Sunday of the month.     |
| dom3rdMon  | The third Monday of the month.     |
| dom3rdTue  | The third Tuesday of the month.    |
| dom3rdWen  | The third Wednesday of the month.  |
| dom3rdThu  | The third Thursday of the month.   |
| dom3rdFri  | The third Friday of the month.     |
| dom3rdSat  | The third Saturday of the month.   |
| dom4thSun  | The fourth Sunday of the month.    |
| dom4thMon  | The fourth Monday of the month.    |
| dom4thTue  | The fourth Tuesday of the month.   |
| dom4thWen  | The fourth Wednesday of the month. |
| dom4thThu  | The fourth Thursday of the month.  |
| dom4thFri  | The fourth Friday of the month.    |
| dom4thSat  | The fourth Saturday of the month.  |
| domLastSun | The last Sunday of the month.      |
| domLastMon | The last Monday of the month.      |
| domLastTue | The last Tuesday of the month.     |
| domLastWen | The last Wednesday of the month.   |
| domLastThu | The last Thursday of the month.    |
| domLastFri | The last Friday of the month.      |
| domLastSat | The last Saturday of the month.    |

**Compatibility** On Palm OS versions earlier than 4.0, this type was named `DayOfWeekType`.

## TimeFormatType

The `TimeFormatType` enum specifies the different display formats for time values.

```
typedef enum
{
    tfColon,
    tfColonAMPM,
    tfColon24h,
    tfDot,
    tfDotAMPM,
    tfDot24h,
    tfHoursAMPM,
    tfHours24h,
    tfComma24h,
} TimeFormatType;

typedef TimeFormatType *TimeFormatPtr;
```

### Value Descriptions

|                          |                                                                                                       |
|--------------------------|-------------------------------------------------------------------------------------------------------|
| <code>tfColon</code>     | The hour and minutes separated by a colon character. For example, 1:00.                               |
| <code>tfColonAMPM</code> | The hour and minutes separated by a colon and followed by an AM/PM indication. For example, 1:00 pm.  |
| <code>tfColon24h</code>  | The 24-hour time with the hour and minutes separated by a colon character. For example, 13:00.        |
| <code>tfDot</code>       | The hour and minutes separated by a dot character. For example, 1.00.                                 |
| <code>tfDotAMPM</code>   | The hour and minutes separated by a period and followed by an AM/PM indication. For example, 1.00 pm. |

## Time Manager

### Time Manager Constants

---

|                          |                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------|
| <code>tfDot24h</code>    | The 24-hour time with the hour and minutes separated by a dot character. For example, 13.00.   |
| <code>tfHoursAMPM</code> | The hour value followed by an AM/PM indication. For example, 1 pm.                             |
| <code>tfHours24h</code>  | The 24-hour value, followed by an AM/PM indication. For example, 13.                           |
| <code>tfComma24h</code>  | The 24-hour time with the hour and minutes separated by a comma character. For example, 13,00. |

## TimeType

The `TimeType` structure represents a time value.

```
typedef struct {
    UInt8    hours;
    UInt8    minutes;
} TimeType;
typedef TimeType *TimePtr;
```

### Field Descriptions

`hours` The number of hours. This is a value between 0 and 23.

`minutes` The number of minutes. This is value between 0 and 59.

## Time Manager Constants

The following table shows the constants that represent the maximum lengths of strings returned by the date and time formatting routines [DateToAscii](#), [DateToDOWDMFormat](#), and [TimeToAscii](#).

| <b>Constant</b>                   | <b>Value</b> | <b>Description</b>                                                                                             |
|-----------------------------------|--------------|----------------------------------------------------------------------------------------------------------------|
| <code>dateStringLength</code>     | 9            | Maximum length of the string returned by <code>DateToAscii</code> for short date formats.                      |
| <code>longDateStrLength</code>    | 15           | Maximum length of the string returned by <code>DateToAscii</code> for medium and long date formats.            |
| <code>timeStringLength</code>     | 9            | Maximum length of the string returned by <code>TimeToAscii</code> .                                            |
| <code>dowDateStringLength</code>  | 19           | Maximum length of the string returned by <code>DateToDOWDMFormat</code> for short date formats.                |
| <code>dowLongDateStrLength</code> | 25           | Maximum length of the string returned by <code>DateToDOWDMFormat</code> for both medium and long date formats. |

---

## Time Manager Functions

### DateAdjust

|                               |                                                                                                                                                                                                                                                              |                              |                                                                                 |                               |                                                 |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|---------------------------------------------------------------------------------|-------------------------------|-------------------------------------------------|
| <b>Purpose</b>                | Return a new date +/- the days adjustment.                                                                                                                                                                                                                   |                              |                                                                                 |                               |                                                 |
| <b>Declared In</b>            | <code>DateTime.h</code>                                                                                                                                                                                                                                      |                              |                                                                                 |                               |                                                 |
| <b>Prototype</b>              | <code>void DateAdjust (DatePtr dateP, Int32 adjustment)</code>                                                                                                                                                                                               |                              |                                                                                 |                               |                                                 |
| <b>Parameters</b>             | <table><tr><td><code>&lt;-&gt; dateP</code></td><td>A pointer to a <a href="#">DateType</a> structure with the date to be adjusted.</td></tr><tr><td><code>-&gt; adjustment</code></td><td>The number of days by which to adjust the date.</td></tr></table> | <code>&lt;-&gt; dateP</code> | A pointer to a <a href="#">DateType</a> structure with the date to be adjusted. | <code>-&gt; adjustment</code> | The number of days by which to adjust the date. |
| <code>&lt;-&gt; dateP</code>  | A pointer to a <a href="#">DateType</a> structure with the date to be adjusted.                                                                                                                                                                              |                              |                                                                                 |                               |                                                 |
| <code>-&gt; adjustment</code> | The number of days by which to adjust the date.                                                                                                                                                                                                              |                              |                                                                                 |                               |                                                 |
| <b>Result</b>                 | Returns nothing. Upon return, <code>dateP</code> contains the adjusted date.                                                                                                                                                                                 |                              |                                                                                 |                               |                                                 |

## Time Manager

### Time Manager Functions

---

**Comments** This function advances the date and manages month and year wrapping conditions.

**See Also** [TimAdjust](#)

## DateDaysToDate

**Purpose** Converts a date specified as the number of days since January 1, 1904 to a [DateType](#) structure.

**Declared In** `DateTime.h`

**Prototype** `void DateDaysToDate (UInt32 days, DatePtr date)`

**Parameters**

|          |                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------|
| -> days  | The number of days since 1/1/1904.                                                               |
| <-> date | A pointer to a <a href="#">DateType</a> structure that is updated with the computed date values. |

**Result** Returns nothing. Upon return, the date information is returned in the structure referenced by the `date` parameter.

**See Also** [DateSecondsToDate](#), [DateToDays](#)

## DateSecondsToDate

**Purpose** Converts a date specified as the number of seconds since January 1, 1904 to a [DateType](#) structure.

**Declared In** `DateTime.h`

**Prototype** `void DateSecondsToDate (UInt32 seconds, DatePtr date)`

**Parameters**

|            |                                       |
|------------|---------------------------------------|
| -> seconds | The number of seconds since 1/1/1904. |
|------------|---------------------------------------|

`<- date`            A pointer to a [DateType](#) structure that is updated with the computed date values.

**Result**            Returns nothing. The structure referenced by the `date` parameter is updated with the date information.

**See Also**          [DateDaysToDate](#), [DateToDays](#)

## **DateTemplateToAscii**

**Purpose**            Convert the specified date values into a string that is formatted according to a formatting template specification.

**Declared In**      `DateTime.h`

**Prototype**        `UInt16 DateTemplateToAscii (const Char *templateP, UInt8 months, UInt8 days, UInt16 years, Char *stringP, Int16 stringLen)`

**Parameters**

- `-> templateP`      A pointer to the template string used to format the date.  
See the Comments section below for details on how to specify date formatting in this template string.
- `-> months`          The month number, which must be a value between 1 and 12.
- `-> days`            The day number, which must be a value between 1 and 31.
- `-> years`            The four-digit year number. For example, 1995.
- `<- stringP`        A pointer to a string that is updated with the result.  
If `stringP` is `NULL`, this function does not write an output string; however, it does return the length required for the output string.

## Time Manager

### Time Manager Functions

---

If `stringP` is not `NULL`, this function writes the formatted string to `stringP`, writing up to `stringSize` bytes into `stringP`.

-> `stringLen`    The size of the `stringP` buffer.

**Result**    The length of the formatted string, without the terminating null byte.

The `DateTemplateToAscii` returns the required length of the formatted string even if the `stringP` parameter is `NULL`; this allows you to determine the buffer size at runtime.

**Comments**    This function is intended as a replacement for the [DateToAscii](#) and [DateToDOWDMFormat](#) functions.

This function uses the formatting template referenced by `templateP` to create a formatted string from the date values that you pass in.

You specify a series of formatting substrings in `templateP`. Each substring has the form:

---

`^<valueType><formatModifier>`

---

Each substring has three components:

- The `^` character begins a substring.
- The `<valueType>` component is a single-digit value that specifies the value type.
- The `<formatModifier>` component is a single-letter value that specifies how you want that value formatted.

The following is an example of a template specification with three substrings:

`^0z ^2l ^4r`

[Table 52.1](#) shows the values you can specify for the `<valueType>` component. Note that the formatted result depends on the `<modifier>` value.

**Table 52.1 Template value types for the  
DateTemplateToAscii function**

| Value | Value type   | Formatted examples |
|-------|--------------|--------------------|
| 0     | Day number   | 1, 01, 23, 31      |
| 1     | Day name     | Tue, Tuesday       |
| 2     | Month name   | May, Aug, August   |
| 3     | Month number | 4, 04, 11          |
| 4     | Year number  | 97, 1997           |

[Table 52.2](#) shows the values you can specify for the <modifier> component of each template substring.

**Table 52.2 Template modifier types for the  
DateTemplateToAscii function**

| Modifier | Description                                        |
|----------|----------------------------------------------------|
| s        | Formats the value in short form                    |
| r        | Formats the value in regular form                  |
| l        | Formats the value in long form                     |
| z        | Adds a leading zero to the formatted numeric value |

Finally, [Table 52.3](#) shows examples of each value type formatted with each modifier type.

**Table 52.3 Examples of formatted values**

| Value type        | Raw value | s<br>(Short format) | r<br>(Regular format) | l<br>(Long format) | z<br>(Zero format) |
|-------------------|-----------|---------------------|-----------------------|--------------------|--------------------|
| 0<br>(Day number) | 2         | 2                   | 2                     | 2                  | 02                 |
| 1<br>(Day name)   | 2         | T                   | Tue                   | Tuesday            | n/a                |

## Time Manager

### Time Manager Functions

---

**Table 52.3 Examples of formatted values (*continued*)**

| Value type       | Raw value | s (Short format) | r (Regular format) | l (Long format) | z (Zero format) |
|------------------|-----------|------------------|--------------------|-----------------|-----------------|
| 2 (Month name)   | 11        | N                | Nov                | November        | n/a             |
| 3 (Month number) | 11        | 11               | 11                 | 11              | 11              |
| 4 (Year number)  | 2000      | 00               | 2000               | 2000            | n/a             |

---

For example, calling `DateTemplateToAscii` as follows:

```
DateTemplateToAscii("^0z ^2l ^4r", 2, 7, 2000, myStr, 20)
```

Produces the following formatted string:

```
07 February 2000
```

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `DateGlueTemplateToAscii`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [DateToAscii](#), [DateToDOWDMFormat](#)

## DateToAscii

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                        |                                                           |                      |                                                         |                       |                                                |                            |                                            |                         |                                                                                                                                                                                                                                                                                                                                                                        |

## Time Manager

### Time Manager Functions

---

small from a form, for an element such as a label or title. Then, the buffer overflow can clobber objects that follow the form in memory. When a form element's location information is corrupted, it disappears from the display.

Note that you can use the [DateTemplateToAscii](#) function instead of this function if the 3.5 feature set is present. You can call the [DateTemplateToAscii](#) function with a NULL string buffer to predetermine the required size for your buffer.

**See Also** [TimeToAscii](#), [DateToDOWDMFormat](#), [DateTemplateToAscii](#)

## DateToDays

**Purpose** Convert the [DateType](#) structure to the number of days elapsed from January 1, 1904.

**Declared In** `DateTime.h`

**Prototype** `UInt32 DateToDays (DateType date)`

**Parameters** `-> date` A [DateType](#) structure.

**Result** Returns the number of days elapsed from January 1, 1904 to the specified date.

**See Also** [DateDaysToDate](#)

## DateToDOWDMFormat

- Purpose** Convert a date to a formatted string using the format specified by the `dateFormat` parameter. The resultant string includes the name of the day of the week.
- Declared In** `DateTime.h`
- Prototype**  
`void DateToDOWDMFormat (UInt8 months, UInt8 days, UInt16 years, DateFormatType dateFormat, Char *pString)`
- Parameters**
- > `months` The month number, which must be a value between 1 and 12.
  - > `days` The day number, which must be a value between 1 and 31.
  - > `years` The four-digit year number. For example, 1995.
  - > `dateFormat` Any [DateFormatType](#) format.
  - <- `pString` A pointer to a string that is updated with the result. The string must be of length `dowDateStringLength` for short formats or `dowLongDateStrLength` for medium or long date formats. See [Time Manager Constants](#) for string buffer lengths.
- Result** Returns nothing. The string referenced by `pString` is updated with the formatted string.
- Comments** The values of some of the [Time Manager Constants](#) that specify the required string buffer lengths do change from time to time. You should always use the constants or verify the required lengths by checking the `datetime.h` file.
- It is important to allocate enough space for your string buffer. Finding buffer overflow errors can be difficult when using a debug ROM. One common situation is when you pass a buffer that is too small from a form, for an element such as a label or title. Then, the

## Time Manager

### Time Manager Functions

---

buffer overflow can clobber objects that follow the form in memory. When a form element's location information is corrupted, it disappears from the display.

Note that you can use the [DateTemplateToAscii](#) function instead of this function if the 3.5 feature set is present. You can call the [DateTemplateToAscii](#) function with a NULL string buffer to predetermine the required size for your buffer.

**Compatibility** On Palm OS 3.1 Japanese ROMs, this function contains a bug that prevented it from properly displaying 4-byte long day names. To prevent this bug from affecting your application, use `DateGlueToDOWDMFormat` in the PalmOSGlue library instead of calling this function directly. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [DateToAscii](#), [DateTemplateToAscii](#)

## DayOfMonth

**Purpose** Return a value that represents the day of a month on which the specified date occurs. The value represents a quantity such as "First Monday" or "Third Friday" as is used for repeating appointments in the Datebook.

**Declared In** `DateTime.h`

**Prototype** `Int16 DayOfMonth (Int16 month, Int16 day, Int16 year)`

**Parameters**

|          |                                                           |
|----------|-----------------------------------------------------------|
| -> month | The month number, which must be a value between 1 and 12. |
| -> day   | The day number, which must be a value between 1 and 31.   |
| -> year  | The four-digit year number. For example, 1995.            |

**Result** Returns a value that represents day of the month. This value is one of the [DayOfMonthType](#) values.

**Comments** The returns value can be used to specify on which day of the month an appointment repeats.

## **DayOfWeek**

**Purpose** Return the day of the week value for a specified date.

**Declared In** `DateTime.h`

**Prototype** `Int16 DayOfWeek (Int16 month, Int16 day, Int16 year)`

**Parameters**

- > `month`            The month number, which must be a value between 1 and 12.
- > `day`                The day number, which must be a value between 1 and 31.
- > `year`                The four-digit year number. For example, 1995.

**Result** Returns one of the following values for the day of the week of the specified date, as shown in the following table:

| <b>Day name</b> | <b>Returned day value</b> |
|-----------------|---------------------------|
| Sunday          | 0                         |
| Monday          | 1                         |
| Tuesday         | 2                         |
| Wednesday       | 3                         |
| Thursday        | 4                         |
| Friday          | 5                         |
| Saturday        | 6                         |

## **DaysInMonth**

- Purpose** Return the number of days in the month.
- Declared In** `DateTime.h`
- Prototype** `Int16 DaysInMonth (Int16 month, Int16 year)`
- Parameters**
- > `month` The month number, which must be a value between 1 and 12.
  - > `year` The four-digit year number. For example, 1995.
- Result** Returns the number of days in the month for the specified year.

## **TimAdjust**

- Purpose** Return a new date, with the time adjusted by the specified number of seconds.
- Declared In** `DateTime.h`
- Prototype** `void TimAdjust (DateTimePtr dateTimeP, Int32 adjustment)`
- Parameters**
- <-> `dateTimeP` A pointer to a [DateType](#) structure.
  - > `adjustment` The number of seconds by which to adjust the time.
- Result** Returns nothing. The structure referenced by `dateTimeP` is modified to contain the updated date and time.
- Comments** This function advances the time by the specified number of seconds and takes care of any wraparound conditions.
- See Also** [DateAdjust](#)

## **TimDateTimeToSeconds**

- Purpose** Return the number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the specified date and time.
- Declared In** `DateTime.h`
- Prototype** `UInt32 TimDateTimeToSeconds (DateTimePtr dateTimeP)`
- Parameters** `-> dateTimeP` A pointer to a [DateTimeType](#) structure.
- Result** The number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the date referenced by `dateTimeP`.
- See Also** [TimSecondsToDateTime](#)

## **TimGetSeconds**

- Purpose** Return the current date and time of the device in seconds since 12:00 A.M. on January 1, 1904.
- Declared In** `TimeMgr.h`
- Prototype** `UInt32 TimGetSeconds (void)`
- Parameters** None.
- Result** The number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the current date and time on the device.
- See Also** [TimSetSeconds](#)

## Time Manager

### Time Manager Functions

---

#### TimGetTicks

- Purpose** Return the tick count since the last reset. The tick count does not advance while the device is in sleep mode.
- Declared In** `TimeMgr.h`
- Prototype** `UInt32 TimGetTicks (void)`
- Parameters** None.
- Result** Returns the tick count.
- Comments** You can call the [SysTicksPerSecond](#) routine to determine the number of ticks per second.
- See Also** [SysTicksPerSecond](#)

#### TimSecondsToDateTime

- Purpose** Converts a date specified as the number of seconds since January 1, 1904 to a [DateTimeType](#) structure.
- Declared In** `DateTime.h`
- Prototype** `void TimSecondsToDateTime (UInt32 seconds, DateTimePtr dateTimeP)`
- Parameters** `-> seconds` A date specified as the number of seconds elapsed from 12:00 A.M. on January 1, 1904 to the date

`<- dateTimeP` A pointer to a [DateTimeType](#) structure that is updated with the date and time values.

**Result** Returns nothing. The structure referenced by `dateTimeP` is updated with the date and time computed for the number of seconds since 12:00 A.M. on January 1, 1904.

**See Also** [TimDateTimeToSeconds](#)

## TimSetSeconds

**Purpose** Set the clock of the device to the date and time passed as the number of seconds since 12:00 A.M. on January 1, 1904.

**Declared In** `TimeMgr.h`

**Prototype** `void TimSetSeconds (UInt32 seconds)`

**Parameters** `-> seconds` The number of seconds since 12:00 A.M. on January 1, 1904.

**Result** Returns nothing.

**Comments** If the [Notification Feature Set](#) is present, this function broadcasts the `sysNotifyTimeChangeEvent` to all interested parties. See [Chapter 39, "Notification Manager,"](#) for more information.

**See Also** [TimGetSeconds](#)

## Time Manager

### Time Manager Functions

---

## TimeToAscii

- Purpose** Convert the time to a string that is formatted according to the specified `timeFormat`.
- Declared In** `DateTime.h`
- Prototype** `void TimeToAscii (UInt8 hours, UInt8 minutes, TimeFormatType timeFormat, Char *pString)`
- Parameters**
- > `hours` The number of hours. This must be a value between 0 and 23.
  - > `minutes` The number of minutes. This must be a value between 0 and 59.
  - > `timeFormat` The time format for the resultant string. This must be one of the [TimeFormatType](#) values.
  - <- `pString` A pointer to a string that is updated with the resultant string. This string must be of length `timeStringLength`.  
See [Time Manager Constants](#) for information on string buffer lengths.
- Result** Returns nothing. The string referenced by `pString` is updated with the formatted string.
- Comments** If you are using a debug ROM in Palm OS 3.5, the string buffer is filled with `timeStringLength` debugging bytes.  
It is important to allocate enough space for your string buffer. Finding buffer overflow errors can be difficult when using a debug ROM. One common situation is when you pass a buffer that is too small from a form, for an element such as a label or title. Then, the buffer overflow can clobber objects that follow the form in memory. When a form element's location information is corrupted, it disappears from the display.
- See Also** [DateToAscii](#)

## TimeZoneToAscii

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                             |                                                                                 |                            |                                                                                                                                                                                                                                         |                           |                                                                                                                        |

| <code>&lt;- string</code>   | A pointer to a string in which to return the result. This string must be of length <code>timeZoneStringLength</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                             |                                                                                 |                            |                                                                                                                                                                                                                                         |                           |                                                                                                                        |
| <b>Result</b>               | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                             |                                                                                 |                            |                                                                                                                                                                                                                                         |                           |                                                                                                                        |
| <b>Comments</b>             | This function returns a descriptive string for the specified time zone. This string identifies the time zone first by its country, such as “USA (Mountain)” or “Canada (Eastern).” If the function cannot find a time zone that matches the specified GMT offset and country, it returns a string containing the time zone as a numeric offset from the GMT (for example, “GMT+9:00”).                                                                                                                                                                                                                                   |                             |                                                                                 |                            |                                                                                                                                                                                                                                         |                           |                                                                                                                        |
| <b>Compatibility</b>        | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                             |                                                                                 |                            |                                                                                                                                                                                                                                         |                           |                                                                                                                        |

## TimTimeZoneToUTC

- Purpose** Converts a date and time from a given time zone to Universal Coordinated Time (UTC). UTC is also known as Greenwich Mean Time (GMT).
- Declared In** `DateTime.h`
- Prototype** `UInt32 TimTimeZoneToUTC (UInt32 seconds, Int16 timeZone, Int16 daylightSavingAdjustment)`
- Parameters**
- > `seconds` The number of seconds since 12:00 A.M. on January 1, 1904.
  - > `timeZone` The time zone, given as the number of minutes east of UTC. For time zones west of UTC but before the international dateline, this is a negative number.
  - > `daylightSavingAdjustment` The number of minutes to add to the current time for daylight savings time in this time zone.
- Result** Returns the same time as `seconds` but in the Universal Coordinated Time. The value is still given as the number of seconds since 12:00 A.M. on January 1, 1904.
- Comments** The returned value is not necessarily the time in Greenwich because Greenwich may be observing daylight saving time.
- You can use this function to convert the local time to UTC. The time zone and the daylight savings adjustment are system preferences that can be retrieved using [PrefGetPreference](#). For example, the following code converts the current local time to UTC:
- ```
Int16 timeZone =
    PrefGetPreference(prefTimeZone);
Int16 daylightSavingAdjustment =
    PrefGetPreference(
        prefDaylightSavingAdjustment);
UInt32 utcTime =
```

```
TimTimeZoneToUTC (TimGetSeconds (), timeZone,  
daylightSavingAdjustment) ;
```

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TimUTCToTimeZone](#)

## TimUTCToTimeZone

**Purpose** Converts a date and time from Universal Coordinated Time (UTC) to the specified time zone. UTC is also known as Greenwich Mean Time (GMT).

**Declared In** `DateTime.h`

**Prototype** `UInt32 TimUTCToTimeZone (UInt32 seconds,  
Int16 timeZone, Int16 daylightSavingAdjustment)`

**Parameters**

-> seconds	The number of seconds since 12:00 A.M. on January 1, 1904 in UTC.
-> timeZone	The time zone, given as the number of minutes east of UTC. For time zones west of UTC before the international dateline, this is a negative number.
-> daylightSavingAdjustment	The number of minutes to add to the current time for daylight savings time in this time zone.

**Result** Returns the same time as `seconds` but in the specified time zone. The value is still given as the number of seconds since 12:00 A.M. on January 1, 1904.

**Comments** The `seconds` value is not necessarily the time in Greenwich because Greenwich may be observing daylight saving time.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TimTimeZoneToUTC](#)

## **Time Manager**

### *Time Manager Functions*

---

# Virtual File System Manager

---

The Virtual File System (VFS) Manager is a layer of software that manages all installed file system libraries. It provides a unified API to application developers while allowing them to seamlessly access many different types of file systems—such as VFAT, HFS, and NFS—on many different types of media, including Compact Flash, Memory Stick, and SmartMedia. This chapter provides reference material for the VFS Manager API as follows:

- [VFS Manager Data Structures](#)
- [VFS Manager Constants](#)
- [VFS Manager Functions](#)
- [Application-Defined Functions](#)

The header file `VFSMgr.h` declares the VFS Manager API. For more information on the VFS Manager, see [Chapter 7, “Expansion,”](#) in *Palm OS Programmer’s Companion*, vol. I.

Note that the VFS Manager is an optional system extension; the functions described in this chapter are implemented only if the [VFS Manager Feature Set](#) is present.

## VFS Manager Data Structures

### FileInfoType

The `FileInfoType` structure contains information about a specified file or directory. This information is returned as a parameter to [VFSDirEntryEnumerate](#). The structure is defined as follows:

```
typedef struct FileInfoTag {
    UInt32 attributes;
```

## Virtual File System Manager

### VFS Manager Data Structures

---

```
    Char *nameP;  
    UInt16 nameBufLen;  
} FileInfoType, *FileInfoPtr;
```

#### Field Descriptions

attributes	Characteristics of the file or directory. See <a href="#">File and Directory Attributes</a> for the bits that make up this field.
nameP	Pointer to the buffer that receives the full name of the file or directory. Initialize this parameter to NULL if you don't want to receive the name.
nameBufLen	Size of the nameP buffer, in bytes.

#### FileRef

The FileRef type is used to encode references to files and directories.

```
typedef UInt32 FileRef;
```

#### VFSAnyMountParamType

The VFSAnyMountParamType structure is a base structure for [VFSSlotMountParamType](#), [VFSPoSEMountParamType](#), and other similar structures that may be defined in the future. Use one or the other according to how you set the mountClass parameter.

```
typedef struct VFSAnyMountParamTag {  
    UInt16 volRefNum;  
    UInt16 reserved;  
    UInt32 mountClass;  
} VFSAnyMountParamType;  
  
typedef VFSAnyMountParamType  
*VFSAnyMountParamPtr;
```

### Field Descriptions

<code>volRefNum</code>	The volume reference number. This is initially obtained when you successfully mount a volume. It can then be used to format a volume with <a href="#">VFSVolumeFormat</a> or unmount a volume with <a href="#">VFSVolumeUnmount</a> .
<code>reserved</code>	Reserved for future use.
<code>mountClass</code>	Defines the type of mount to use with the specified volume. See <a href="#">Volume Mount Classes</a> for a list of mount types.

### VFSSlotMountParamType

The `VFSSlotMountParamType` structure is used when you are mounting a card located in an Expansion Manager slot. The `vfsMountParam->mountClass` field must be set to `VFSMountClass_SlotDriver`.

```
typedef struct VFSSlotMountParamTag {
    VFSAnyMountParamType vfsMountParam;
    UInt16 slotLibRefNum;
    UInt16 slotRefNum;
} VFSSlotMountParamType;
```

### Field Descriptions

<code>vfsMountParam</code>	See the description of <a href="#">VFSAnyMountParamType</a> for an explanation of the fields in this structure. Set <code>vfsMountParam-&gt;mountClass</code> to <code>VFSMountClass_SlotDriver</code> to mount an Expansion Manager slot.
<code>slotLibRefNum</code>	Reference number for the slot driver library allocated to the given slot number. Obtain this field by calling <a href="#">ExpSlotLibFind</a> .
<code>slotRefNum</code>	Number of the slot to be mounted.

## VFSPoSEMountParamType

The `VFSPoSEMountParamType` structure is used when you are mounting a volume through the Palm OS® Emulator. The `vfsMountParam->mountClass` must be set to `VFSMountClass_POSE`. Note that ordinary applications and file systems shouldn't use `VFSPoSEMountParamType`.

```
typedef struct VFSPoSEMountParamTag {
    VFSAnyMountParamType vfsMountParam;
    UInt8 poseSlotNum;
} VFSPoSEMountParamType
```

### Field Descriptions

<code>vfsMountParam</code>	See the description of <a href="#">VFSAnyMountParamType</a> for an explanation of the fields in this structure. Set <code>vfsMountParam-&gt;mountClass</code> to <code>VFSMountClass_POSE</code> to mount a virtual slot.
<code>poseSlotNum</code>	Number of the virtual slot number to be mounted by the Palm OS Emulator.

## VolumeInfoType

The `VolumeInfoType` structure defines information that is returned to [VFSVolumeInfo](#) and used throughout the VFS functions.

```
typedef struct VolumeInfoTag {
    UInt32 attributes;
    UInt32 fsType;
    UInt32 fsCreator;
    UInt32 mountClass;
    UInt16 slotLibRefNum;
    UInt16 slotRefNum;
    UInt32 mediaType;
    UInt32 reserved;
} VolumeInfoType, *VolumeInfoPtr;
```

### Field Descriptions

<code>attributes</code>	Characteristics of the volume. See <a href="#">Volume Attributes</a> for the bits that make up this field.
<code>fsType</code>	File system type for this volume. See <a href="#">Defined File Systems</a> for a list of the supported file systems.
<code>fsCreator</code>	Creator ID of this volume's file system driver. This information is used with <a href="#">VFSCustomControl</a> .
<code>mountClass</code>	Mount class that mounted this volume. The supported mount classes are listed under <a href="#">Volume Mount Classes</a> .
<code>slotLibRefNum</code>	Reference to the slot driver library with which the volume is mounted. This field is only valid when the mount class is <code>vfsMountClass_SlotDriver</code> .
<code>slotRefNum</code>	Slot number where the card containing the volume is loaded. This field is only valid when the mount class is <code>vfsMountClass_SlotDriver</code> .
<code>mediaType</code>	Type of card media. See <a href="#">Defined Media Types</a> in the <a href="#">Expansion Manager</a> chapter for the list of values. This field is only valid when the mount class is <code>vfsMountClass_SlotDriver</code> .
<code>reserved</code>	Reserved for future use.

## VFS Manager Constants

### Defined File Systems

The following file systems are currently defined by the VFS Manager. These values are used with [VFSVolumeInfo](#) in the `VolumeInfoType.fsType` parameter.

## Virtual File System Manager

### *VFS Manager Constants*

---

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>vfsFilesystemType_AFS</code>	<code>'afsu'</code>	Unix Andrew file system
<code>vfsFilesystemType_EXT2</code>	<code>'ext2'</code>	Linux file system
<code>vfsFilesystemType_FAT</code>	<code>'fats'</code>	FAT12 and FAT16, which only handles 8.3 filenames
<code>vfsFilesystemType_FFS</code>	<code>'ffsb'</code>	Unix Berkeley block based file system
<code>vfsFilesystemType_HFS</code>	<code>'hfss'</code>	Macintosh standard hierarchical file system
<code>vfsFilesystemType_HFSPlus</code>	<code>'hfse'</code>	Macintosh extended hierarchical file system
<code>vfsFilesystemType_HPFS</code>	<code>'hpfs'</code>	OS2 High Performance file system
<code>vfsFilesystemType_MFS</code>	<code>'mfso'</code>	Macintosh original file system
<code>vfsFilesystemType_NFS</code>	<code>'nfsu'</code>	Unix Networked file system
<code>vfsFilesystemType_Novell</code>	<code>'novl'</code>	Novell file system
<code>vfsFilesystemType_NTFS</code>	<code>'ntfs'</code>	Windows NT file system
<code>vfsFilesystemType_VFAT</code>	<code>'vfat'</code>	FAT12 and FAT16 extended to handle long filenames

---

## Open Mode Constants

This section describes constants that are used for the `openMode` parameter to the [VFSFileOpen](#) function. These constants specify the mode in which a file or directory is opened.

Constant	Value	Description
<code>vfsModeExclusive</code>	<code>0x0001U</code>	Open and lock the file or directory. This mode excludes anyone else from using the file or directory until it is closed.
<code>vfsModeRead</code>	<code>0x0002U</code>	Open for read access.
<code>vfsModeWrite</code>	<code>0x0004U   vfsModeExclusive</code>	Open for write access.
<code>vfsModeReadWrite</code>	<code>vfsModeWrite   vfsModeRead</code>	Open for read/write access.
<code>vfsModeCreate</code>	<code>0x0008U</code>	Create the file if it doesn't already exist. This open mode is implemented in the VFS layer, rather than in the file system library.
<code>vfsModeTruncate</code>	<code>0x0010U</code>	Truncate the file to zero (0) bytes after opening, removing all existing data. This open mode is implemented in the VFS layer, rather than in the file system library.
<code>vfsModeVFSLayerOnly</code>	<code>vfsModeCreate   vfsModeTruncate</code>	Mask used to isolate those flags that are only used by the VFS layer. These flags are not passed to the file system layer.
<code>vfsModeLeaveOpen</code>	<code>0x0020U</code>	Leave the file open even after the application exits.

## Virtual File System Manager

### VFS Manager Constants

---

### File and Directory Attributes

The constants in the following table define bits that can be used individually or in combination when setting or interpreting the file attributes for a given file or directory. See [VFSFileGetAttributes](#), [VFSFileSetAttributes](#), and the [FileInfoType](#) data structure for specific use.

Constant	Value	Description
<code>vfsFileAttrReadOnly</code>	<code>0x00000001UL</code>	Read-only file or directory
<code>vfsFileAttrHidden</code>	<code>0x00000002UL</code>	Hidden file or directory
<code>vfsFileAttrSystem</code>	<code>0x00000004UL</code>	System file or directory
<code>vfsFileAttrVolumeLabel</code>	<code>0x00000008UL</code>	Volume label
<code>vfsFileAttrDirectory</code>	<code>0x00000010UL</code>	Directory
<code>vfsFileAttrArchive</code>	<code>0x00000020UL</code>	Archived file or directory
<code>vfsFileAttrLink</code>	<code>0x00000040UL</code>	Link to another file or directory

---

### Volume Attributes

The constants in the following table define bits that can be used individually or in combination to make up the attributes field in the [VolumeInfoType](#) structure.

Constant	Value	Description
<code>vfsVolumeAttrHidden</code>	<code>0x00000004UL</code>	The volume should not be visible to the user.
<code>vfsVolumeAttrReadOnly</code>	<code>0x00000002UL</code>	The volume is read only.
<code>vfsVolumeAttrSlotBased</code>	<code>0x00000001UL</code>	Reserved. Check the mount class to determine how a volume is mounted.

---

## Volume Mount Classes

The following constants define how a given volume is mounted. The `mountClass` field in the [VFSAnyMountParamType](#) and [VolumeInfoType](#) structures takes on one of these values.

Constant	Value	Description
<code>vfsMountClass_POSE</code>	<code>'pose'</code>	Mount the volume through the Palm OS Emulator. This is used for testing.
<code>vfsMountClass_Simulator</code>	<code>sysFileTsimulator</code>	Mount the volume through the simulator. This is used for testing.
<code>vfsMountClass_SlotDriver</code>	<code>sysFileTslotDriver</code>	Mount the volume with a slot driver shared library.

---

## Error Codes

The VFS Manager defines the following error codes:

Constant	Description
<code>vfsErrBadData</code>	The operation could not be completed because of invalid data.
<code>vfsErrBadName</code>	Invalid filename, path, or volume label.
<code>vfsErrBufferOverflow</code>	The supplied buffer is too small.
<code>vfsErrDirectoryNotFound</code>	Returned when the path leading up to the file does not exist.
<code>vfsErrDirNotEmpty</code>	The directory is not empty and therefore cannot be deleted.

---

### *VFS Manager Constants*

---

<b>Constant</b>	<b>Description</b>
<code>vfsErrFileAlreadyExists</code>	A file with this name exists already in this location.
<code>vfsErrFileBadRef</code>	The file reference is invalid: it has been closed or was not obtained from <a href="#">VFSFileOpen</a> .
<code>vfsErrFileEOF</code>	The file pointer is at the end of the file.
<code>vfsErrFileGeneric</code>	Generic file error.
<code>vfsErrFileNotFound</code>	The file was not found at the specified location.
<code>vfsErrFilePermissionDenied</code>	The requested permissions could not be granted.
<code>vfsErrFileStillOpen</code>	Returned from the underlying file system's delete function if the file is still open.
<code>vfsErrIsADirectory</code>	This operation can only be performed on a regular file, not a directory.
<code>vfsErrNameShortened</code>	A volume name or filename was automatically shortened to conform to the file system specification.
<code>vfsErrNoFileSystem</code>	None of the installed file systems support this operation.
<code>vfsErrNotADirectory</code>	This operation can only be performed on a directory.
<code>vfsErrVolumeBadRef</code>	The volume reference number is invalid.

<b>Constant</b>	<b>Description</b>
<code>vfsErrVolumeFull</code>	There is insufficient space left on the volume.
<code>vfsErrVolumeStillMounted</code>	Returned from the underlying file system's format function if the volume is still mounted.

## VFS Manager Functions

### VFSCustomControl

<b>Purpose</b>	Make a custom API call to a particular file system, given its creator ID. You can use <a href="#">VFSVolumeInfo</a> to determine the creator ID of the file system for a given volume.
<b>Declared In</b>	<code>VfsMgr.h</code>
<b>Prototype</b>	<pre>Err VFSCustomControl (UInt32 fsCreator, UInt32 apiCreator, UInt16 apiSelector, void *valueP, UInt16 *valueLenP)</pre>
<b>Parameters</b>	<p>-&gt; <code>fsCreator</code> Creator of the file system to call. A value of zero (0) tells the VFS Manager to check each registered file system, looking for one which supports the call.</p> <p>-&gt; <code>apiCreator</code> Registered creator ID.</p> <p>-&gt; <code>apiSelector</code> Custom operation to perform.</p> <p>&lt;-&gt; <code>valueP</code> A pointer to a buffer containing data specific to the operation. On exit, depending on the function of the particular custom call and on the value of <code>valueLenP</code>, the contents of this buffer may have been updated.</p>

## Virtual File System Manager

### VFS Manager Functions

---

`<-> valueLenP` On entry, points to the size of the `valueP` buffer. On exit, this value reflects the size of the data written to the `valueP` buffer. If `valueLenP` is `NULL`, `valueP` is passed to the file system but is not updated on exit.

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`expErrUnsupportedOperation`  
The specified opcode and/or creator is unsupported or undefined.

`sysErrParamErr` The `valueP` buffer is too small.

`vfsErrNoFileSystem`  
VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The driver identifies the call and its API by a registered creator ID and a selector. This allows file system developers to extend the API by defining selectors for their creator IDs. It also allows file system developers to support selectors (and custom calls) defined by other file system developers.

This function must return `expErrUnsupportedOperation` for all unsupported or undefined opcodes and/or creators.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSDirCreate

- Purpose** Create a new directory.
- Declared In** `VfsMgr.h`
- Prototype** `Err VFSDirCreate(UInt16 volRefNum,  
const Char *dirNameP)`
- Parameters**
- > `volRefNum` Volume reference number returned from [VFSVolumeEnumerate](#).
  - > `dirNameP` Pointer to the full path of the directory to be created.
- Result** Returns one of the following error codes:
- `errNone` No error
  - `expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.
  - `vfsErrBadName` Some or all of the path, up to but not including the last component specified in the `dirNameP` parameter, does not exist.
  - `vfsErrFileAlreadyExists`  
A file with this name already exists in this location.
  - `vfsErrNoFileSystem`  
The VFS Manager cannot find an appropriate file system to handle the request.
  - `vfsErrVolumeBadRef`  
The volume has not been mounted.
  - `vfsErrVolumeFull`  
There is not enough space left on the volume.
- Comments** All parts of the path except the last component must already exist. The `vfsFileAttrDirectory` attribute is set with this function.

## Virtual File System Manager

### VFS Manager Functions

---

[VFSDirCreate](#) does not open the directory. Any operations you want to perform on this directory require a reference, which is obtained through a call to [VFSFileOpen](#).

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSDirEntryEnumerate

**Purpose** Enumerate the entries in a given directory. Entries can include files, links, and other directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSDirEntryEnumerate (FileRef dirRef, UInt32 *dirEntryIteratorP, FileInfoType *infoP)`

**Parameters**

<code>-&gt; dirRef</code>	Directory reference returned from <a href="#">VFSFileOpen</a> .
<code>&lt;-&gt; dirEntryIteratorP</code>	Pointer to the index of the last entry enumerated. For the first iteration, initialize this parameter to the constant <code>vfsIteratorStart</code> . Upon return, this references the next entry in the directory. If <code>infoP</code> is the last entry, this parameter is set to <code>vfsIteratorStop</code> .
<code>&lt;-&gt; infoP</code>	Pointer to the <a href="#">FileInfoType</a> data structure that contains information about the given directory entry. The <code>nameP</code> and <code>nameBufLen</code> fields in this structure must be initialized prior to calling <code>VFSDirEntryEnumerate</code> .

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrEnumerationEmpty</code>	There are no directory entries left to enumerate.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`sysErrParamErr` The `dirEntryIteratorP` is not valid.

`vfsErrFileBadRef`  
The specified file reference is invalid.

`vfsErrIsNotADirectory`  
The specified file reference is valid, but does not point to a directory.

`vfsErrNoFileSystem`  
The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The directory to be enumerated must first be opened with [VFSFileOpen](#) in order to obtain a file reference. In order to obtain information on all entries in a directory you must make repeated calls to `VFSDirEntryEnumerate` inside a loop. Boundaries on the iteration are the defined constants `vfsIteratorStart` and `vfsIteratorStop`. Before the first call to `VFSDirEntryEnumerate`, `dirEntryIteratorP` should be initialized to `vfsIteratorStart`. Each iteration then changes the value pointed to by `dirEntryIteratorP`. When information on the last entry in the directory is returned, `dirEntryIteratorP` is set to `vfsIteratorStop`.

---

**WARNING!** Creating, renaming, or deleting any file or directory invalidates the enumeration. After any such operation, the enumeration will need to be restarted.

---

**Example** The following code excerpt illustrates how to use `VFSDirEntryEnumerate`.

---

```
FileInfoType info;
FileRef dirRef;
UInt32 dirIterator;
Char *fileName = MemPtrNew(256); // should check for err

// open the directory first, to get the directory reference
// volRefNum must have already been defined
```

## Virtual File System Manager

### VFS Manager Functions

---

```
err = VFSFileOpen(volRefNum, "/", vfsModeRead, &dirRef);
if(err == errNone) {

    info.nameP = fileName;    // point to local buffer
    info.nameBufLen = 256;
    dirIterator = vfsIteratorStart
    while (dirIterator != vfsIteratorStop) {
        // Get the next file
        err = VFSDirEntryEnumerate (dirRef, &dirIterator,
            &info);
        if (err == errNone) {
            // Do something with the directory entry information
            // Pull the attributes from info.attributes
            // The file name is in fileName
        } else {
            // handle error, possibly by breaking out of the
loop
        }
    } else {
        // handle directory open error here
    }
    MemPtrFree(fileName);
}
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSExportDatabaseToFile

**Purpose** Save the specified database to a .pdb or .prc file on an external storage card.

**Declared In** VfsMgr.h

**Prototype** Err VFSExportDatabaseToFile (UInt16 volRefNum,  
const Char \*pathNameP, UInt16 cardNo,  
LocalID dbID)

**Parameters**

- > volRefNum Volume on which the destination file should be created.
- > pathNameP Pointer to the complete path and name of the destination file to be created.

- > cardNo            Card number on which the .pdb or .prc being exported resides.
- > dbID              ID of the database being exported.

**Result**    Returns one of the following error codes:

- errNone            No error
- expErrNotEnoughPower    There is insufficient battery power to perform the database export operation.
- vfsErrBadName    The path name specified in pathNameP is not valid.

**Comments**    This utility function exports a database from main memory to a .pdb or .prc file on an external storage card. This function is the opposite of [VFSImportDatabaseFromFile](#). It first creates the file specified in the pathNameP parameter with [VFSFileCreate](#). After opening the file the Exchange Manager function [ExgDBWrite](#) is called with an internal callback function for exporting the file from the Data Manager. The Exchange Manager makes repeated calls to this callback function, which receives the data back in blocks. Once all the data has been exported, VFS Manager closes the file.

This function is used, for example, to copy applications from main memory to a storage card.

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**        [VFSExportDatabaseToFileCustom](#), [VFSFileWrite](#), [VFSImportDatabaseFromFile](#)

## **VFSExportDatabaseToFileCustom**

**Purpose**         Saves the specified database to a .pdb or .prc file on an external storage card. This function differs from

## Virtual File System Manager

### VFS Manager Functions

---

[VFSExportDatabaseToFile](#) in that it allows you to track the progress of the export operation.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSExportDatabaseToFileCustom  
(UInt16 volRefNum, const Char *pathNameP,  
UInt16 cardNo, LocalID dbID,  
VFSExportProcPtr exportProcP, void *userDataP)`

**Parameters**

- > `volRefNum` Volume on which the destination file should be created.
- > `pathNameP` Pointer to the complete path and name of the destination file to be created.
- > `cardNo` Card number on which the `.pdb` or `.prc` being exported resides.
- > `dbID` ID of the database being exported.
- > `exportProcP` User-defined callback function that tracks the progress of the export. This function should allow the user to cancel the export. Pass `NULL` if you don't have a progress callback function. See [VFSExportProcPtr](#) for the requirements of this function.
- > `userDataP` Pointer to any data you want to pass to the callback function specified in `exportProcP`. This information is not used internally by the VFS Manager. Pass `NULL` if you don't have a progress callback function or if that function doesn't need any such data.

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotEnoughPower`  
There is insufficient battery power to perform the database export operation.

`vfsErrBadName` The path name specified in `pathNameP` is not valid.

This function can also return any error code other than `errNone` produced by your callback function.

**Comments** This function is similar to [VFSExportDatabaseToFile](#) in that it exports a database from main memory to a `.pdb` or `.prc` file on an external storage card. It extends the functionality by allowing you to specify a callback function that tracks the progress of the export. It first creates the file specified in the `pathNameP` parameter with [VFSFileCreate](#). After opening the file, the Exchange Manager function [ExgDBWrite](#) is called with an internal callback function for exporting the file from the Data Manager. Exchange Manager makes repeated calls to this function, which receives the data back in blocks. The progress tracker, if one has been specified, is also called every time a new chunk of data is passed back. Once all the data has been exported, the VFS Manager closes the file.

This function is used, for example, to copy applications from main memory to a storage card.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFile](#), [VFSFileWrite](#), [VFSImportDatabaseFromFileCustom](#)

## VFSFileClose

**Purpose** Closes a file or directory that has been opened with [VFSFileOpen](#).

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileClose (FileRef fileRef)`

**Parameters** `-> fileRef` File reference number returned from [VFSFileOpen](#).

**Result** Returns one of the following error codes:

## Virtual File System Manager

### VFS Manager Functions

---

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrFileBadRef</code>	The specified file reference is invalid.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileCreate

**Purpose** Create a file. This function cannot be used to create a directory; use [VFSDirCreate](#) instead.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileCreate(UInt16 volRefNum,  
const Char *pathNameP)`

**Parameters**

- > `volRefNum` Reference number of the volume on which to create the file. This volume reference number is returned from [VFSVolumeEnumerate](#).
- > `pathNameP` Pointer to the full path of the file to be created. All parts of the path, excluding the filename, must already exist.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrBadName</code>	The <code>pathNameP</code> is invalid.
<code>vfsErrFileAlreadyExists</code>	A file with this name already exists in this location.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The volume has not been mounted.

`vfsErrVolumeFull`

There is not enough space left on the volume.

**Comments** It is the responsibility of the file system library to ensure that all filenames are translated into a format that is compatible with the native format of the file system, such as the 8.3 convention for a FAT file system without long filename support. See [Naming Files](#) in the [Expansion](#) chapter of the *Palm OS Programmer's Companion*, vol. I for a description of how to construct a valid path.

This function does not open the file. Use [VFSFileOpen](#) to open the file.

This function should not be used to create a directory. To create a directory use [VFSDirCreate](#).

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileDelete](#)

## VFSFileDBGetRecord

**Purpose** Load a record from an opened `.pdb` file on an external card into the storage heap.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileDBGetRecord (FileRef ref,  
UInt16 recIndex, MemHandle *recHP,  
UInt8 *recAttrP, UInt32 *uniqueIDP)`

**Parameters** `-> ref` The file reference returned from [VFSFileOpen](#). Note that the open file must be a `.pdb` file.

## Virtual File System Manager

### VFS Manager Functions

---

-> recIndex	The index of the record to load.
<- recHP	Pointer to the record data's handle in the storage heap. If NULL is returned in this parameter there is either no data in this field or an error occurred reading this data from the file. If the handle is not NULL, you must dispose of the allocated handle using <a href="#">MemHandleFree</a> .
<- recAttrP	Pointer to the attributes of the record. The values returned are identical to the attributes returned from <a href="#">DmRecordInfo</a> . See <a href="#">Record Attribute Constants</a> in the <a href="#">Data and Resource Manager</a> chapter for a description of each attribute. Pass NULL for this parameter if you do not want to retrieve this information.
<- uniqueIDP	Pointer to the unique identifier for this record. Pass NULL for this parameter if you do not want to retrieve this information.

**Result** Returns one of the following error codes:

errNone	No error.
dmErrIndexOutOfRange	The recIndex is out of range.
dmErrNotRecordDB	The file referenced by ref is not a record database.
memErrNotEnoughSpace	There is not enough space in memory for the requested record entry.
sysErrParamErr	A NULL value was passed in for the recHP, recAttrP, and uniqueIDP parameters.
vfsErrBadData	The local offsets (localChunkID) from the top of the .pdb to the start of the raw record data for this entry are out of order.

**Comments** This function is analogous to [DmGetRecord](#) but works with files on an external card rather than databases in main memory. This

function allocates a handle of the appropriate size from the storage heap and returns it in the `resHP` parameter. The caller is responsible for freeing this memory, using [MemHandleFree](#), when it is no longer needed.

---

**NOTE:** This function is not efficient for multiple accesses and should be used sparingly.

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileReadData](#)

## VFSFileDBGetResource

**Purpose** Load a resource into the storage heap from an opened `.prc` file.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileDBGetResource (FileRef ref,  
DmResType type, DmResID resID, MemHandle *resHP)`

**Parameters**

-> <code>ref</code>	The file reference returned from <a href="#">VFSFileOpen</a> . Note that the open file must be a <code>.prc</code> file.
-> <code>type</code>	The type of resource to load. See the <a href="#">Data and Resource Manager</a> chapter for more information on resources.
-> <code>resID</code>	The ID of resource to load.
<- <code>resHP</code>	Pointer to the resource data handle that was loaded into memory.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
----------------------	-----------

## Virtual File System Manager

### VFS Manager Functions

---

`dmErrNotResourceDB`

The file referenced by `ref` is not a resource database.

`dmErrResourceNotFound`

The requested resource was not found.

`memErrNotEnoughSpace`

There is not enough space in memory for the requested resource entries.

`sysErrParamErr` `resHP` is NULL.

#### Comments

This function locates the specified resource in the open `.prc` file. See the *Palm OS File Format Specification* for more information on the layout of `.prc` files.

Once the resource is found, `VFSFileDBGetResource` allocates a handle of the appropriate size in the storage heap and reads it into memory. The handle to this memory location is returned through the `resHP` parameter. The caller is responsible for freeing this memory, using [MemHandleFree](#), when it is no longer needed.

---

**NOTE:** This function is not efficient for multiple accesses and should be used sparingly.

---

#### Compatibility

Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileDBInfo

<b>Purpose</b>	Get information about a database represented by an open .prc or .pdb file.										
<b>Declared In</b>	VfsMgr.h										
<b>Prototype</b>	<pre>Err VFSFileDBInfo (FileRef ref, Char *nameP, UInt16 *attributesP, UInt16 *versionP, UInt32 *crDateP, UInt32 *modDateP, UInt32 *bckUpDateP, UInt32 *modNumP, MemHandle *appInfoHP, MemHandle *sortInfoHP, UInt32 *typeP, UInt32 *creatorP, UInt16 *numRecordsP)</pre>										
<b>Parameters</b>	<table><tr><td>-&gt; ref</td><td>The file reference returned from <a href="#">VFSFileOpen</a>. Note that the open file must be a .prc or .pdb file.</td></tr><tr><td>&lt;- nameP</td><td>Pointer to a 32-byte character array in which the database name is returned. Pass NULL for this parameter if you do not want to retrieve the database name.</td></tr><tr><td>&lt;- attributesP</td><td>Pointer to the database attributes stored in the file. The values returned are identical to the attributes returned from <a href="#">DmDatabaseInfo</a>. See the <a href="#">Database Attribute Constants</a> section for a description of each attribute. Pass NULL for this parameter if you do not want to retrieve the database's attributes.</td></tr><tr><td>&lt;- versionP</td><td>Pointer to the application-specific version number of the database. The default version number is zero (0). Pass NULL for this parameter if you do not want to retrieve the version number.</td></tr><tr><td>&lt;- crDateP</td><td>Pointer to the date the database was created, expressed in seconds since midnight (00:00:00) January 1, 1904. Pass NULL for this parameter if you do not want to retrieve the creation date.</td></tr></table>	-> ref	The file reference returned from <a href="#">VFSFileOpen</a> . Note that the open file must be a .prc or .pdb file.	<- nameP	Pointer to a 32-byte character array in which the database name is returned. Pass NULL for this parameter if you do not want to retrieve the database name.	<- attributesP	Pointer to the database attributes stored in the file. The values returned are identical to the attributes returned from <a href="#">DmDatabaseInfo</a> . See the <a href="#">Database Attribute Constants</a> section for a description of each attribute. Pass NULL for this parameter if you do not want to retrieve the database's attributes.	<- versionP	Pointer to the application-specific version number of the database. The default version number is zero (0). Pass NULL for this parameter if you do not want to retrieve the version number.	<- crDateP	Pointer to the date the database was created, expressed in seconds since midnight (00:00:00) January 1, 1904. Pass NULL for this parameter if you do not want to retrieve the creation date.
-> ref	The file reference returned from <a href="#">VFSFileOpen</a> . Note that the open file must be a .prc or .pdb file.										
<- nameP	Pointer to a 32-byte character array in which the database name is returned. Pass NULL for this parameter if you do not want to retrieve the database name.										
<- attributesP	Pointer to the database attributes stored in the file. The values returned are identical to the attributes returned from <a href="#">DmDatabaseInfo</a> . See the <a href="#">Database Attribute Constants</a> section for a description of each attribute. Pass NULL for this parameter if you do not want to retrieve the database's attributes.										
<- versionP	Pointer to the application-specific version number of the database. The default version number is zero (0). Pass NULL for this parameter if you do not want to retrieve the version number.										
<- crDateP	Pointer to the date the database was created, expressed in seconds since midnight (00:00:00) January 1, 1904. Pass NULL for this parameter if you do not want to retrieve the creation date.										

## Virtual File System Manager

### VFS Manager Functions

---

- `<- modDateP` Pointer to the date the database was last modified, expressed in seconds since midnight (00:00:00) January 1, 1904. A database's modification date is updated only if a change has been made to the database when it is opened with write access. Pass `NULL` for this parameter if you do not want to retrieve the database's modification date.
- `<- bckUpDateP` Pointer to the date the database was last backed up, expressed in seconds since midnight (00:00:00) January 1, 1904. Pass `NULL` for this parameter if you do not want to retrieve the database's backup date.
- `<- modNumP` Pointer to the number of times the database was modified. This number is updated every time a record is added, modified, or deleted. Pass `NULL` for this parameter if you do not want to retrieve the modification count.
- `<- appInfoHP` Pointer to the application info block handle. If `NULL` is returned in this parameter, either there is no data in this field or an error occurred reading this data from the file. If a value other than `NULL` is returned, you must dispose of the allocated handle using [MemHandleFree](#). If you do not want to retrieve the application info block, pass `NULL` for this parameter
- `<- sortInfoHP` Pointer to the sort info block handle. If `NULL` is returned in this parameter, either there is no data in this field or an error occurred reading this data from the file. If a value other than `NULL` is returned, you must dispose of the allocated handle using [MemHandleFree](#). Pass `NULL` for this parameter if you do not want to retrieve the sort info block handle.

`<- typeP`      Pointer to the type of database as it was created. This may be a user-defined database type or a database type defined by the Palm OS. Some of the more common database types returned here are:

<b>Type</b>	<b>Description</b>
'appl'	Standard Palm™ application (resource database)
'libr'	Standard shared library
'libf'	File system shared library
'libs'	Slot driver shared library
'data'	Standard Palm data file (record database)

Pass NULL for this parameter if you do not want to retrieve the database's type.

`<- creatorP`      Pointer to the database's creator. Pass NULL for this parameter if you do not want to retrieve this information.

`<- numRecordsP`      Pointer to the number of records in the database. Pass NULL for this parameter if you do not want to retrieve this information.

**Result**      Returns one of the following error codes:

`errNone`      No error

`memErrNotEnoughSpace`      There is not enough space in memory for the database header.

`vfsErrBadData`      The file referenced by the `ref` parameter is too small to contain a database header, or the database header is corrupted.

## Virtual File System Manager

### VFS Manager Functions

---

**Comments** This function is analogous to [DmDatabaseInfo](#), but it works with files on an external card rather than with databases in main memory. See the *Palm OS File Format Specification* for a description of the header block in .prc and .pdb files.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileGetAttributes](#), [VFSFileGetDate](#)

## VFSFileDelete

**Purpose** Deletes a closed file or directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileDelete(UInt16 volRefNum,  
const Char *pathNameP)`

**Parameters**

-> volRefNum	Volume reference number returned from <a href="#">VFSVolumeEnumerate</a> .
-> pathNameP	Pointer to the full path of the file or directory to be deleted.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrBadName</code>	The path name specified in pathNameP is not valid.
<code>vfsErrDirNotEmpty</code>	The directory being deleted is not empty.
<code>vfsErrFileStillOpen</code>	The file is still open.
<code>vfsErrFileNotFound</code>	The file could not be found.

`vfsErrFilePermissionDenied`

The requested permissions could not be granted.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The volume has not been mounted.

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

## **VFSFileEOF**

**Purpose**    Get end-of-file status for an open file. This function only operates on files and cannot be used with directories.

**Declared In**    `VfsMgr.h`

**Prototype**    `Err VFSFileEOF (FileRef fileRef)`

**Parameters**    `-> fileRef`    File reference returned from [VFSFileOpen](#).

**Result**    Returns one of the following error codes:

`errNone`    No error. File pointer is not at end of the file.

`vfsErrFileEOF`    The file pointer is at the end of file.

`expErrNotOpen`    The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

## Virtual File System Manager

### VFS Manager Functions

---

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileGetAttributes

**Purpose** Obtain the attributes of an open file or directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileGetAttributes (FileRef fileRef, UInt32 *attributesP)`

**Parameters**

- > `fileRef` File reference returned from [VFSFileOpen](#).
- <- `attributesP` Pointer to the attributes associated with the file or directory. See [File and Directory Attributes](#) for a list of values that can be returned through this parameter.

**Result** Returns one of the following error codes:

`errNone` No error

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`  
The specified file reference is invalid.

`vfsErrNoFileSystem`  
The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileDBInfo](#), [VFSFileGetDate](#), [VFSFileSetAttributes](#)

## VFSFileGetDate

<b>Purpose</b>	Obtain the dates on an open file or directory.						
<b>Declared In</b>	VfsMgr.h						
<b>Prototype</b>	Err VFSFileGetDate (FileRef fileRef, UInt16 whichDate, UInt32 *dateP)						
<b>Parameters</b>	<table><tr><td>-&gt; fileRef</td><td>File reference returned from <a href="#">VFSFileOpen</a>.</td></tr><tr><td>-&gt; whichDate</td><td>Specifies which date—creation, modification, or last access—you want. Supply one of the following values:  vfsFileDateCreated  vfsFileDateModified  vfsFileDateAccessed  Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.</td></tr><tr><td>&lt;- dateP</td><td>Pointer to the requested date. This field is expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.</td></tr></table>	-> fileRef	File reference returned from <a href="#">VFSFileOpen</a> .	-> whichDate	Specifies which date—creation, modification, or last access—you want. Supply one of the following values:  vfsFileDateCreated  vfsFileDateModified  vfsFileDateAccessed  Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.	<- dateP	Pointer to the requested date. This field is expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.
-> fileRef	File reference returned from <a href="#">VFSFileOpen</a> .						
-> whichDate	Specifies which date—creation, modification, or last access—you want. Supply one of the following values:  vfsFileDateCreated  vfsFileDateModified  vfsFileDateAccessed  Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.						
<- dateP	Pointer to the requested date. This field is expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.						
<b>Result</b>	Returns one of the following error codes: <table><tr><td>errNone</td><td>No error.</td></tr><tr><td>expErrNotOpen</td><td>The file system library necessary for this call has not been installed or has not been opened.</td></tr><tr><td>expErrUnsupportedOperation</td><td>The specified date type is not supported by the underlying file system.</td></tr></table>	errNone	No error.	expErrNotOpen	The file system library necessary for this call has not been installed or has not been opened.	expErrUnsupportedOperation	The specified date type is not supported by the underlying file system.
errNone	No error.						
expErrNotOpen	The file system library necessary for this call has not been installed or has not been opened.						
expErrUnsupportedOperation	The specified date type is not supported by the underlying file system.						

## Virtual File System Manager

### VFS Manager Functions

---

`vfsErrFileBadRef`

The specified file reference is invalid.

`sysErrParamErr` The `whichDate` parameter is not one of the defined constants.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileDBInfo](#), [VFSFileGetAttributes](#), [VFSFileSetDate](#)

## VFSFileOpen

**Purpose** Opens a file or directory and returns a reference for it.

**Declared In** `VfsMgr.h`

**Prototype**

```
Err VFSFileOpen (UInt16 volRefNum,
const Char *pathNameP, UInt16 openMode,
FileRef *fileRefP)
```

**Parameters**

- > `volRefNum` The volume reference number returned from [VFSVolumeEnumerate](#).
- > `pathNameP` Pointer to the full path of the file or directory to be opened. This must be a valid path. It cannot be empty and can not contain null characters. The format of the pathname should match what the underlying file system supports. See "[Naming Files](#)" in [Chapter 7, "Expansion,"](#) of the *Palm OS Programmer's Companion*, vol. I for a description of how to construct a valid path.
- > `openMode` Mode to use when opening the file. See the [Open Mode Constants](#) section for a list of accepted modes.

<- fileRefP      Pointer to the opened file or directory reference which is supplied to various other VFSFile... operations. This value is filled in on return.

**Result**      Returns one of the following error codes:

errNone          No error.

expErrCardReadOnly

The open mode requested includes write access but the file is read-only.

expErrNotOpen    The file system library necessary for this call has not been installed or has not been opened.

vfsErrBadName    The pathNameP parameter is invalid.

vfsErrFileNotFound

The specified file or directory could not be found.

vfsErrFilePermissionDenied

The file cannot be opened in the requested open mode, or it has already been opened with `vfsModeExclusive`.

vfsErrVolumeBadRef

The specified volume has not been mounted.

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**        [VFSFileClose](#), [VFSDirEntryEnumerate](#)

## Virtual File System Manager

### VFS Manager Functions

---

## VFSFileRead

**Purpose** Read data from a file into the dynamic heap. This function only operates on files and cannot be used with directories; use [VFSDirEntryEnumerate](#) to explore the contents of a directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileRead (FileRef fileRef,  
UInt32 numBytes, void *bufP,  
UInt32 *numBytesReadP)`

**Parameters**

- > `fileRef` File reference returned from [VFSFileOpen](#).
- > `numBytes` Number of bytes to read.
- <- `bufP` Pointer to the destination chunk where the data is to be stored. This can be a pointer to any writable memory.
- <- `numBytesReadP` Pointer to an unsigned integer that reflects the number of bytes actually read. This value is set on return and does not need to be initialized. If no bytes are read the value is set to zero. Pass NULL for this parameter if you do not need to know how many bytes were read.

**Result** Returns one of the following error codes:

- `errNone` No error.
- `expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.
- `vfsErrFileBadRef` The specified file reference is invalid.
- `vfsErrFileEOF` The end of the file has been reached.
- `vfsErrFilePermissionDenied` Read permission is not enabled for this file.

`vfsErrIsADirectory`

The specified file reference is for a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The file system does not use [DmWrite](#) and cannot be used to read data into the storage heap.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileReadData](#), [VFSFileWrite](#),  
[VFSImportDatabaseFromFile](#)

## VFSFileReadData

**Purpose** Read data from a file into a chunk of memory in the storage heap. This function only operates on files and cannot be used with directories; use [VFSDirEntryEnumerate](#) to explore the contents of a directory.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileReadData (FileRef fileRef,  
UInt32 numBytes, void *bufBaseP, UInt32 offset,  
UInt32 *numBytesReadP)`

**Parameters**

-> fileRef	File reference returned in <a href="#">VFSFileOpen</a> .
-> numBytes	Number of bytes to read.
<- bufBaseP	Pointer to the destination chunk in the storage heap where the data is to be stored. This pointer must be obtained through the appropriate call to the <a href="#">Memory Manager</a> API.
-> offset	Offset, in bytes, within the bufBaseP chunk where the data is to be written.

## Virtual File System Manager

### VFS Manager Functions

---

`<- numBytesReadP`

Pointer to an unsigned integer that reflects the number of bytes actually read. This value is set on return and does not need to be initialized. If no bytes are read, the value is set to zero. Pass NULL for this parameter if you do not need to know how many bytes were read.

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`  
The specified file reference is invalid.

`vfsErrFileEOF` The end of the file has been reached.

`vfsErrFilePermissionDenied`  
Read permission is not enabled for this file.

`vfsErrIsADirectory`  
The specified file reference is for a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`  
The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** When data is read from an external card with `VFSFileReadData`, it is copied into a chunk of memory in the storage heap. This chunk **must** be allocated by the application before the call to [VFSFileReadData](#). This function calls [DmWrite](#) to put the data in the storage heap.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileRead](#), [VFSFileWrite](#)

## VFSFileRename

**Purpose** Rename a closed file or directory. This function cannot be used to move a file to another directory within the file system.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileRename (UInt16 volRefNum,  
const Char *pathNameP, const Char *newNameP)`

**Parameters**

- > `volRefNum` Volume reference number returned from [VFSVolumeEnumerate](#).
- > `pathNameP` Pointer to the full path of the file or directory to be renamed.
- > `newNameP` Pointer to the new filename. Note that this is the name of the file only and does not include the path to the file.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrBadName</code>	The name provided in either <code>pathNameP</code> or <code>newNameP</code> is invalid. This is also returned if the string pointed to by <code>newNameP</code> is a path, rather than a filename.
<code>vfsErrFileAlreadyExists</code>	A file with the new name already exists in this location.
<code>vfsErrFileNotFound</code>	The source file could not be found.
<code>vfsErrFilePermissionDenied</code>	Write permission is not enabled for this file.

## Virtual File System Manager

### *VFS Manager Functions*

---

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The volume has not been mounted.

`vfsErrVolumeFull`

There is not enough space left on the volume.

---

**Comments**    **WARNING!** This function invalidates directory enumeration. You cannot continue enumerating files after renaming one of them with this function. If you need to operate on additional files in the directory, you must first restart the enumeration.

---

**Example**    Below is an example of how to use `VFSFileRename`. Note that the renamed file remains in the `/PALM/Programs` directory; `VFSFileRename` can't be used to move files from one directory to another.

---

```
// volRefNum must have been previously defined; most likely,  
// it was returned by VFSVolumeEnumerate  
  
err = VFSFileRename(volRefNum, "/PALM/Programs/foo.prc",  
    "bar.prc");  
if (err != errNone) {  
    // handle error...  
}
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSFileResize

**Purpose** Change the size of an open file. This function only operates on files and cannot be used with directories.

**Declared In** VfsMgr.h

**Prototype** Err VFSFileResize (FileRef fileRef,  
 UInt32 newSize)

**Parameters**

- > fileRef File reference returned from [VFSFileOpen](#).
- > newSize The desired new size of the file. This can be larger or smaller than the current file size.

**Result** Returns one of the following error codes:

errNone No error.

expErrNotOpen The file system library necessary for this call has not been installed or has not been opened.

vfsErrFileBadRef  
The specified file reference is invalid.

vfsErrIsADirectory  
The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

## Virtual File System Manager

### VFS Manager Functions

---

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeFull`

There is not enough space left on the volume.

**Comments** The location of the file pointer is undefined after a call to this function.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileSize](#)

## VFSFileSeek

**Purpose** Set the position within an open file from which to read or write. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileSeek (FileRef fileRef,  
FileOrigin origin, Int32 offset)`

**Parameters**

- > `fileRef` File reference returned from [VFSFileOpen](#).
- > `origin` Origin to use when calculating the new position. The `offset` parameter indicates the desired new position relative to this origin, which can be one of the following:
  - `vfsOriginBeginning`  
The beginning of the file.
  - `vfsOriginCurrent`  
The current position within the file.
  - `vfsOriginEnd`  
The end of the file. Only negative offsets are allowed when `origin` is set to `vfsOriginEnd`.

-> offset            Offset, either positive or negative, from the origin to which the current position should be set. A value of zero (0) positions you at the specified origin.

**Result**            Returns one of the following error codes:

errNone              No error.

expErrNotOpen        The file system library necessary for this call has not been installed or has not been opened.

vfsErrFileBadRef     The specified file reference is invalid.

vfsErrFileEOF        The file pointer is at the end of file.

vfsErrIsADirectory    The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

sysErrParamErr      The specified origin is not one of the defined constants.

**Comments**         During a call to this function, if the resulting position would be beyond the end of the file, it sets the position to the end of the file.

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**           [VFSFileSize](#), [VFSFileTell](#)

## **VFSFileSetAttributes**

**Purpose**             Change the attributes of an open file or directory.

**Declared In**        VfsMgr.h

**Prototype**         Err VFSFileSetAttributes (FileRef fileRef,  
                          UInt32 attributes)

## Virtual File System Manager

### VFS Manager Functions

---

**Parameters**

- > fileRef File reference returned from [VFSFileOpen](#).
- > attributes Attributes to associate with the file or directory. See [File and Directory Attributes](#) for a list of values you can use when setting this parameter:

**Result** Returns one of the following error codes:

- errNone No error.
- expErrNotOpen The file system library necessary for this call has not been installed or has not been opened.
- sysErrParamErr One of the parameters is invalid.
- vfsErrFileBadRef  
The specified file reference is invalid.
- vfsErrNoFileSystem  
The VFS Manager cannot find an appropriate file system to handle the request.

---

**Comments** **NOTE:** You cannot use this function to set the `vfsFileAttrDirectory` or `vfsFileAttrVolumeLabel` attributes. The `vfsFileAttrDirectory` is set when you call [VFSDirCreate](#). The `vfsFileAttrVolumeLabel` is set when you call [VFSVolumeSetLabel](#). This function may fail when setting other attributes, depending on the underlying file system.

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileGetAttributes](#), [VFSFileSetDate](#)

## VFSFileSetDate

<b>Purpose</b>	Changes the dates on an open file or directory.								
<b>Declared In</b>	VfsMgr.h								
<b>Prototype</b>	Err VFSFileSetDate (FileRef fileRef, UInt16 whichDate, UInt32 date)								
<b>Parameters</b>	<table><tr><td>-&gt; fileRef</td><td>File reference returned in <a href="#">VFSFileOpen</a>.</td></tr><tr><td>-&gt; whichDate</td><td>Specifies which date—creation, modification, or last access—to modify. Supply one of the following values:  vfsFileDateCreated  vfsFileDateModified  vfsFileDateAccessed  Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.</td></tr><tr><td>-&gt; date</td><td>The new date. This field should be expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.</td></tr></table>	-> fileRef	File reference returned in <a href="#">VFSFileOpen</a> .	-> whichDate	Specifies which date—creation, modification, or last access—to modify. Supply one of the following values:  vfsFileDateCreated  vfsFileDateModified  vfsFileDateAccessed  Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.	-> date	The new date. This field should be expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.		
-> fileRef	File reference returned in <a href="#">VFSFileOpen</a> .								
-> whichDate	Specifies which date—creation, modification, or last access—to modify. Supply one of the following values:  vfsFileDateCreated  vfsFileDateModified  vfsFileDateAccessed  Note that not all file systems are required to support the above dates. If the supplied date type is not supported by the file system, VFSFileGetDate returns expErrUnsupportedOperation.								
-> date	The new date. This field should be expressed in the standard Palm OS date format — the number of seconds since midnight (00:00:00) January 1, 1904.								
<b>Result</b>	Returns one of the following error codes: <table><tr><td>errNone</td><td>No error.</td></tr><tr><td>expErrNotOpen</td><td>The file system library necessary for this call has not been installed or has not been opened.</td></tr><tr><td>expErrUnsupportedOperation</td><td>The specified date type is not supported by the underlying file system.</td></tr><tr><td>sysErrParamErr</td><td>The whichDate parameter is not one of the defined constants.</td></tr></table>	errNone	No error.	expErrNotOpen	The file system library necessary for this call has not been installed or has not been opened.	expErrUnsupportedOperation	The specified date type is not supported by the underlying file system.	sysErrParamErr	The whichDate parameter is not one of the defined constants.
errNone	No error.								
expErrNotOpen	The file system library necessary for this call has not been installed or has not been opened.								
expErrUnsupportedOperation	The specified date type is not supported by the underlying file system.								
sysErrParamErr	The whichDate parameter is not one of the defined constants.								

## Virtual File System Manager

### VFS Manager Functions

---

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrFilePermissionDenied`

Write permission is not enabled for this file.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileGetDate](#), [VFSFileSetAttributes](#)

## VFSFileSize

**Purpose** Obtain the size of an open file. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileSize (FileRef fileRef,  
UInt32 *fileSizeP)`

**Parameters**

- > `fileRef` File reference returned from [VFSFileOpen](#).
- <- `fileSizeP` Pointer to the size of the open file.

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`

The specified file reference is invalid.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileResize](#), [VFSFileTell](#), [VFSVolumeSize](#)

## VFSFileTell

**Purpose** Get the current position of the file pointer within an open file. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSFileTell (FileRef fileRef,  
UInt32 *filePosP)`

**Parameters**

<code>-&gt; fileRef</code>	File reference returned from <a href="#">VFSFileOpen</a> .
<code>&lt;- filePosP</code>	Pointer to the current file position.

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`vfsErrFileBadRef`  
The specified file reference is invalid.

`vfsErrIsADirectory`  
The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`  
The VFS Manager cannot find an appropriate file system to handle the request.

## Virtual File System Manager

### VFS Manager Functions

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSFileSeek](#), [VFSFileSize](#)

## VFSFileWrite

**Purpose** Write data to an open file. This function only operates on files and cannot be used with directories.

**Declared In** `VfsMgr.h`

**Prototype**

```
Err VFSFileWrite (FileRef fileRef,  
                UInt32 numBytes, const void *dataP,  
                UInt32 *numBytesWrittenP)
```

**Parameters**

- > `fileRef` File reference returned from [VFSFileOpen](#).
- > `numBytes` The number of bytes to write.
- > `dataP` Pointer to the data that is to be written.
- <- `numBytesWrittenP` Pointer to an unsigned integer that reflects the number of bytes actually written. This value is set on return and does not need to be initialized. If no bytes are written the value is set to zero. Pass NULL for this parameter if you do not need to know how many bytes were written.

**Result** Returns one of the following error codes:

- `errNone` No error.
- `expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.
- `vfsErrFileBadRef` The specified file reference is invalid.
- `vfsErrFilePermissionDenied` Write permission is not enabled for this file.

`vfsErrIsADirectory`

The specified file reference points to a directory instead of a file. This is an invalid operation on a directory.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeFull`

There is not enough space left on the volume.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFile](#),  
[VFSExportDatabaseToFileCustom](#), [VFSFileRead](#),  
[VFSFileReadData](#)

## VFSGetDefaultDirectory

**Purpose** Determine the default location on the given volume for files of a particular type.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSGetDefaultDirectory (UInt16 volRefNum,  
const Char *fileTypeStr, Char *pathStr,  
UInt16 *bufLenP)`

**Parameters**

- > `volRefNum` Volume reference number returned from [VFSVolumeEnumerate](#).
- > `fileTypeStr` Pointer to the requested file type, as a null-terminated string. The file type may either be a MIME media type/subtype pair, such as "image/jpeg", "text/plain", or "audio/basic"; or a file extension, such as ". jpeg."
- <- `pathStr` Pointer to the buffer which receives the default directory path for the requested file type.

## Virtual File System Manager

### VFS Manager Functions

---

<-> bufLenP      Pointer to the size of the path. Set this to the size of pathStr buffer on input. Reflects the number of bytes copied to pathStr on output.

**Result**      Returns one of the following error codes:

errNone          No error.

vfsErrBadName    There is no default directory registered for the requested file type.

vfsErrBufferOverflow      A match was found, but the pathStr buffer is too small to hold the resulting path string. A partial path is returned in pathStr.

vfsErrFileNotFound      No match was found for the specified volume. The error could have occurred with either the media type specified for this volume or the file type requested.

**Comments**      This function returns the complete path to the default directory registered for the specified file type. A default directory can be registered for each type of media supported. The directory should be registered under media and file type. Note that this directory is typically a “root” directory for the file type; any subdirectories under this root directory should also be searched for files of the appropriate type.

This function can be used by an image viewer application, for example, to find the directory containing images without having to know what type of media the volume was on. This could be “/DCIM”, “/images”, or something else depending on the type of media.

**Compatibility**      Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**          [VFSDirEntryEnumerate](#), [VFSRegisterDefaultDirectory](#), [VFSUnregisterDefaultDirectory](#)

## **VFSImportDatabaseFromFile**

**Purpose**      Creates a database from a .pdb or .prc file on an external storage card.

**Declared In**    `VfsMgr.h`

**Prototype**    `Err VFSImportDatabaseFromFile (UInt16 volRefNum,  
const Char *pathNameP, UInt16 *cardNoP,  
LocalID *dbIDP)`

**Parameters**

-> <code>volRefNum</code>	Volume on which the source file resides.
-> <code>pathNameP</code>	Pointer to the full path and name of the source file.
<- <code>cardNoP</code>	Pointer to a variable that receives the card number of the newly-created database. If the database already resides in the storage heap, the card number of the existing database is returned along with the error <code>dmErrAlreadyExists</code> .
<- <code>dbIDP</code>	Pointer to a variable that receives the database ID of the new database. If the database already resides in the storage heap, the database ID of the existing database is returned along with the error <code>dmErrAlreadyExists</code> .

**Result**      Returns one of the following error codes:

`errNone`            No error.

`dmErrAlreadyExists`  
The .prc or .pdb file already exists in the storage heap. In this case the `cardNoP` and `dbIDP` are set to point to the existing file.

`expErrNotEnoughPower`  
There is insufficient battery power to complete the requested operation.

## Virtual File System Manager

### VFS Manager Functions

---

`vfsErrBadName` The path name specified in `pathNameP` is not valid.

**Comments** This utility function imports a `.pdb` or `.prc` file resident on an external storage card into a new database in the storage heap. It first calls [VFSFileOpen](#) to open the file specified in `pathNameP`. Assuming that a corresponding `.prc` or `.pdb` does not already exist in the storage heap, [VFSImportDatabaseFromFile](#) calls the Exchange Manager function [ExgDBRead](#) with an internal callback function for importing a file to the Data Manager. The Exchange Manager makes repeated calls to this function, which passes the data back in blocks. Once the file has been successfully imported, the owner (the imported file, if it's an executable, or the associated application if it is not) is sent a [sysAppLaunchCmdSyncNotify](#) launch code to make it aware of the new database.

This function doesn't provide any progress indication to the user. If you need to provide feedback to the user as the file import progresses, use [VFSImportDatabaseFromFileCustom](#) instead.

This function is used, for example, to copy applications from a storage card to main memory.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSExportDatabaseToFile](#), [VFSFileRead](#)

## VFSImportDatabaseFromFileCustom

**Purpose** Create a database from the specified `.pdb` or `.prc` file on an external storage card. This function differs from

[VFSImportDatabaseFromFile](#) in that it allows you to track the progress of the import operation.

**Declared In**    `VfsMgr.h`

**Prototype**    `Err VFSImportDatabaseFromFileCustom  
(UInt16 volRefNum, const Char *pathNameP,  
UInt16 *cardNoP, LocalID *dbIDP,  
VFSImportProcPtr importProcP, void *userDataP)`

**Parameters**

- > `volRefNum`    Volume on which the source file resides.
- > `pathNameP`    Pointer to the full path and name of the source file.
- <- `cardNoP`        Pointer to the variable that receives the card number of the newly-created database. If the database already resides in the storage heap, the card number of the existing database is returned along with the error `dmErrAlreadyExists`.
- <- `dbIDP`            Pointer to the variable that receives the database ID of the new database. If the database already resides in the storage heap, the database ID of the existing database is returned along with the error `dmErrAlreadyExists`.
- > `importProcP`    User-defined callback function that tracks the progress of the import. This function should allow the user to cancel the import. Pass `NULL` if you don't have a progress callback function. See [VFSImportProcPtr](#) for the requirements of this function.

## Virtual File System Manager

### VFS Manager Functions

---

-> `userDataP` Pointer to any data you want to pass to the callback function specified in `importProcP`. This information is not used internally by the VFS Manager. Pass `NULL` if you don't have a progress callback function, or if that function doesn't need any such data.

**Result** Returns one of the following error codes:

`errNone` No error

`vfsErrBadName` The path name specified in `pathNameP` is not valid.

`expErrNotEnoughPower`  
The power required to import a database is not available.

`dmErrAlreadyExists`  
The `.prc` or `.pdb` file already exists in main memory. In this case the `cardNoP` and `dbIDP` are set to point to the existing file.

**Comments** This function is similar to [VFSImportDatabaseFromFile](#) in that it imports a `.pdb` or `.prc` file on an external storage card into a new database on the storage heap. It extends the functionality by allowing you to specify a callback function that tracks the progress of the export. It first calls [VFSFileOpen](#) to open the file specified in `pathNameP`. If a corresponding `.prc` or `.pdb` does not already exist in main memory, it calls the Exchange Manager function [ExgDBRead](#) with an internal callback function for importing the file from the Data Manager. The Exchange Manager makes repeated calls to this function, which receives the data back in blocks. The progress tracker, if one has been specified, is also called every time a new chunk of data is passed back. Once the file has been successfully imported, the owner (the imported file, if it's an executable, or the associated application if it is not) is sent a [sysAppLaunchCmdSyncNotify](#) launch code to make it aware of the new database.

This function is used, for example, to copy applications from a storage card to main memory.

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**        [VFSFileRead](#), [VFSExportDatabaseToFileCustom](#)

## VFSInstallFSLib

**Purpose**            Install a file system library so that the VFS Manager can use it.

**Declared In**     `VfsMgr.h`

**Prototype**        `Err VFSInstallFSLib (UInt32 creator,  
                      UInt16 *fsLibRefNumP)`

**Parameters**      `-> creator`            Creator ID of the database containing the file system library to be installed.

`<- fsLibRefNumP`        Pointer to the reference number for the newly installed file system library. Supply `NULL` for this parameter if you don't need the library reference number.

**Result**            If the file system library was loaded and installed without error, `errNone` is returned. Any error generated by the underlying file system while opening the file system library or determining its type will be returned from `VFSInstallFSLib`. Other errors that can be generated during the file system library installation process include:

`expErrIncompatibleAPIVer`        The file system library has an incompatible API version.

`expErrNotOpen`            The file system library necessary for this call has not been installed or has not been opened.

`memErrNotEnoughSpace`, `memErrChunkNotLocked`, or `memErrChunkLocked`  
A memory problem occurred while inserting the library reference into the list of installed libraries.

## Virtual File System Manager

### VFS Manager Functions

---

`sysErrLibNotFound`, `sysErrNoFreeRAM`,  
`sysErrNoFreeLibSlots` (or some other  
error returned from the library's install entry  
point)  
An error occurred while loading the library.

**Comments** This function calls [SysLibLoad](#) to load the file system library into the library table. Once loaded the appropriate file system is asked to open the library. At boot time `VFSInstallFSLib` is called internally by the Expansion Manager to load all installed file system libraries and initialize them for use.

`VFSInstallFSLib` is not normally called by applications.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSRemoveFSLib](#)

## VFSRegisterDefaultDirectory

**Purpose** Registers a specific directory as the default location for files of a given type on a particular kind of external storage card. This function is generally called by a slot driver for files and media types that are supported by that slot driver.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSRegisterDefaultDirectory`  
`(const Char *fileTypeStr, UInt32 mediaType,`  
`const Char *pathStr)`

**Parameters** `-> fileTypeStr` Pointer to the file type to register. This is a null-terminated string that can either be a MIME media type/subtype pair, such as "image/jpeg", "text/plain", or "audio/basic"; or a file extension, such as ".jpeg".

- > `mediaType`    Type of card media for which the default directory is being associated. See [Defined Media Types](#) in the [Expansion Manager](#) chapter for the list of accepted values.
- > `pathStr`        Pointer to the default directory path to be associated with the specified file type. This string must be null-terminated, and must be the full path to the directory.

**Result**    Returns one of the following error codes:

- `errNone`            No error.
- `sysErrParamErr`    Either the `fileTypeStr` parameter is NULL or the `pathStr` parameter is NULL.
- `vfsErrFileAlreadyExists`  
A default directory has already been registered for this file type on the specified card media type.

## Virtual File System Manager

### VFS Manager Functions

---

**Comments** This function first verifies that a default directory has not already been registered for the specified combination of file type and media type, and returns `vfsErrFileAlreadyExists` if one has been registered. To change an existing entry in the registry, you must first remove the existing entry with a call to [VFSUnregisterDefaultDirectory](#) before re-registering it with `VFSRegisterDefaultDirectory`.

The specified directory registered for a given file type is intended to be the “root” default directory. If a given default directory has one or more subdirectories, applications should also search those subdirectories for files of the appropriate type.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSGetDefaultDirectory](#)

## VFSRemoveFSLib

**Purpose** Remove a file system library from the library table, so that the VFS Manager can no longer use it.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSRemoveFSLib (UInt16 fsLibRefNum)`

**Parameters** `-> fsLibRefNum` Library reference number of the file system library to remove from the library table.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrNoFileSystem</code>	VFS Manager can not find the file system specified in <code>fsLibRefNum</code> .

**Comments** This function is not normally called by applications. It unmounts any volumes that the specified file system may have mounted. It then closes the library and removes it from the library table with [SysLibRemove](#).

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

## VFSUnregisterDefaultDirectory

**Purpose** Sever the association between a particular file type and a default directory for a given type of card media.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSUnregisterDefaultDirectory  
(const Char *fileTypeStr, UInt32 mediaType)`

**Parameters**

- > `fileTypeStr` Pointer to the file type with which the default directory is associated. This is a null-terminated string that can either be a MIME media type/subtype pair, such as "image/jpeg", "text/plain", or "audio/basic"; or a file extension, such as ".jpeg".
- > `mediaType` Type of card media for which the default directory is associated. See [Defined Media Types](#) in the [Expansion Manager](#) chapter for the list of accepted values.

**Result** Returns one of the following error codes:

`errNone` No error.

`sysErrParamErr` The `fileTypeStr` parameter is NULL.

`vfsErrFileNotFound`

A default directory could not be found in the registry for the specified file and media type.

## Virtual File System Manager

### VFS Manager Functions

---

**Comments** **NOTE:** Caution is advised when using this function, since you may remove another application's registration, causing data to mysteriously disappear from those applications.

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSGetDefaultDirectory](#), [VFSRegisterDefaultDirectory](#)

## VFSVolumeEnumerate

**Purpose** Enumerate the mounted volumes.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeEnumerate (UInt16 *volRefNumP, UInt32 *volIteratorP)`

**Parameters**

`<- volRefNumP` Pointer to the reference number for the volume represented by the current enumeration, or `vfsInvalidVolRef` if there are no more volumes to be enumerated or an error occurred.

`<-> volIteratorP` Pointer to a variable that holds the index of the current enumeration. Set the variable to `vfsIteratorStart` prior to the first iteration. Each call to `VFSVolumeEnumerate` updates the variable to the index of the next volume. When the last volume is reached, the variable pointed to by `volIteratorP` is set to `vfsIteratorStop`.

**Result** Returns one of the following error codes:

`errNone` No error

`expErrEnumerationEmpty` There are no volumes to enumerate.

`sysErrParamErr` The value pointed to by `volIteratorP` is not valid. This error is also returned when `volIteratorP` is `vfsIteratorStop`.

**Comments** This function returns a pointer to the volume reference number in the `volRefNumP` parameter. In order to traverse all volumes you must make repeated calls to [VFSVolumeEnumerate](#) inside a loop. Before the first call to `VFSVolumeEnumerate`, the variable pointed to by `volIteratorP` should be initialized to `vfsIteratorStart`. Each iteration then increments `volIteratorP` to the next entry after updating `volRefNumP`. When the last volume is reached, `*volIteratorP` is set to `vfsIteratorStop`. If there are no volumes to enumerate, `VFSVolumeEnumerate` returns `expErrEnumerationEmpty` when first called.

**Example** Below is an example of how to use `VFSVolumeEnumerate`.

---

```
UInt16 volRefNum;
UInt32 volIterator = vfsIteratorStart;

while (volIterator != vfsIteratorStop) {
    err = VFSVolumeEnumerate(&volRefNum, &volIterator);
    if (err == errNone) {
        // Do something with the volRefNum
    } else {
        // handle error... possibly by
        // breaking out of the loop
    }
}
```

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

### VFSVolumeFormat

- Purpose** Format and mount the volume installed in a given slot.
- Declared In** `VfsMgr.h`
- Prototype** `Err VFSVolumeFormat (UInt8 flags, UInt16 fsLibRefNum, VFSAnyMountParamPtr vfsMountParamP)`
- Parameters**
- > `flags` Flags that control how the volume should be formatted. Currently, the only flag not reserved is `vfsMountFlagsUseThisFileSystem`. Pass this flag to cause the volume to be formatted using the file system specified by `fsLibRefNum`. Pass zero (0) to have the VFS Manager attempt to format the volume using a file system appropriate to the slot.
  - > `fsLibRefNum` Reference number of the file system library for which the volume should be formatted. This number is obtained through a call to [SysLibFind](#) with the name of the library you want to use. If the `flags` field is not set to `vfsMountFlagsUseThisFileSystem`, this parameter is ignored.

`<->vfsMountParamP`

Parameters to be used when formatting the volume and when mounting the volume after it has been formatted. Supply a pointer to either a [VFSSlotMountParamType](#) or a [VFSPoSEMountParamType](#) structure. Note that you'll need to cast your structure pointer to a `VFSAnyMountParamPtr`. Set the `mountClass` field to the appropriate value: if you are mounting to an Expansion Manager slot, set `mountClass` to `VFSMountClass_SlotDriver` and initialize `slotLibRefNum` and `slotRefNum` to the appropriate values. See the descriptions of [VFSAnyMountParamType](#), [VFSSlotMountParamType](#), and [VFSPoSEMountParamType](#) for information on the fields that make up these data structures.

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotEnoughPower`

There is insufficient battery power to format and/or mount a volume.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

**Comments** The slot driver currently only supports one volume per slot. If the volume is successfully formatted and mounted, the reference number of the mounted volume is returned in `vfsMountParamP->volRefNum`. If the format is unsuccessful or cancelled, `vfsMountParamP->volRefNum` is set to `vfsInvalidVolRef`.

If `vfsMountFlagsUseThisFileSystem` is passed as a flag, `VFSVolumeFormat` attempts to format the volume using the file system library specified by `fsLibRefNum`. Typically the flag

## Virtual File System Manager

### VFS Manager Functions

---

parameter is not set. In this case `VFSVolumeFormat` tries to find a compatible library to format the volume, as follows:

1. Check to see if the default file system library feature is set. If it is, and if that file system is installed, it is used to format the volume. You can set the default file system using `FtrSet`; supply `sysFileCVFSMgr` for the feature creator, and `vfsFtrIDDefaultFS` for the feature number.
2. Check to see if any of the installed file systems are natively supported for the slot on which the VFS Manager is trying to format. If one of them is, it is used to format the volume.
3. If none of the installed file systems can perform the format using the slot's native type, a dialog displays warning the user that their media may become incompatible with other devices if they continue with the format. The user may continue or cancel the format. If the user chooses to continue, `VFSVolumeFormat` formats the volume using the first file system library that was installed.

When calling `VFSVolumeFormat`, the volume can either be mounted or unmounted. The underlying file system library call requires the volume to be unmounted. `VFSVolumeFormat` checks to see if the volume is currently mounted and unmounts it, if necessary, using `VFSVolumeUnmount` before making the file system call. If the file system successfully formats the volume, `VFSVolumeFormat` mounts it and posts a `sysNotifyVolumeMountedEvent` notification.

**Example** The following code excerpt formats a volume on an Expansion Manager slot using a compatible file system.

---

```
VFSslotMountParamType slotParam;
UInt32 slotIterator = expIteratorStart;

slotParam.vfsMountParamP.mountClass =
    VFSMountClass_SlotDriver;
err = ExpSlotEnumerate(&slotParam.slotRefNum,
    &slotIterator);
err = ExpSlotLibFind(slotParam.slotRefNum,
    &slotParam.slotLibRefNum);

err = VFSVolumeFormat(NULL, NULL,
    (VFSAnyMountParamPtr) & slotParam);
```

---

**Compatibility**    Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also**        [VFSVolumeMount](#)

## **VFSVolumeGetLabel**

**Purpose**         Determine the volume label for a particular volume.

**Declared In**    `VfsMgr.h`

**Prototype**     `Err VFSVolumeGetLabel(UInt16 volRefNum,  
Char *labelP, UInt16 bufLen)`

**Parameters**

-> volRefNum	Volume reference number returned from <a href="#">VFSVolumeEnumerate</a> .
<- labelP	Pointer to a character buffer into which the volume name is placed.
-> bufLen	Length, in bytes, of the labelP buffer.

**Result**         Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrNoFileSystem</code>	The VFS Manager cannot find an appropriate file system to handle the request.
<code>vfsErrVolumeBadRef</code>	The specified volume has not been mounted.
<code>vfsErrBufferOverflow</code>	The value specified in <code>bufLen</code> is not big enough to receive the full volume label.
<code>vfsErrNameShortened</code>	There was an error reading the full volume name. A shortened version is being returned.

## Virtual File System Manager

### VFS Manager Functions

---

**Comments** Volume reference numbers can change each time you mount a given volume. To keep track of a particular volume, save the volume's label rather than its reference number. Volume labels can be up to 255 characters long. They can contain any normal character, including spaces and lower case characters, in any character set as well as the following special characters: \$ % ' - \_ @ ~ ` ! ( ) ^ # & + , ; = [ ].

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeSetLabel](#)

## VFSVolumeInfo

**Purpose** Get information about the specified volume.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeInfo(UInt16 volRefNum, VolumeInfoType *volInfoP)`

**Parameters**

<code>-&gt; volRefNum</code>	Volume reference number returned from <a href="#">VFSVolumeEnumerate</a> .
<code>&lt;- volInfoP</code>	Pointer to the structure that receives the volume information for the specified volume. See <a href="#">VolumeInfoType</a> for more information on the fields in this data structure.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrNoFileSystem</code>	The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The specified volume reference number is invalid.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeGetLabel](#), [VFSVolumeSize](#)

## VFSVolumeMount

**Purpose** Mount the card's volume on the specified slot.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeMount(UInt8 flags,  
                  UInt16 fsLibRefNum,  
                  VFSAnyMountParamPtr vfsMountParamP)`

**Parameters**

- > `flags` Flags that control how the volume should be mounted. Currently, the only flag not reserved is `vfsMountFlagsUseThisFileSystem`. Pass this flag to cause the volume to be mounted using the file system specified by `fsLibRefNum`. Pass zero (0) to have the VFS Manager attempt to mount the volume using a file system appropriate for the slot.
- > `fsLibRefNum` Reference number of the file system library for which the volume should be mounted. This number is obtained through a call to [SysLibFind](#) with the name of the library you want to use. If the `flags` field is not set to `vfsMountFlagsUseThisFileSystem`, this parameter is ignored.

## Virtual File System Manager

### VFS Manager Functions

---

`<->vfsMountParamP`

Parameters to be used when mounting the volume after it has been formatted. Supply a pointer to either a [VFSSlotMountParamType](#) or a [VFSPOSEMountParamType](#) structure. Note that you'll need to cast your structure pointer to a `VFSAnyMountParamPtr`. Set the `mountClass` field to the appropriate value: if you are mounting to an Expansion Manager slot, set `mountClass` to `VFSMountClass_SlotDriver` and initialize `slotLibRefNum` and `slotRefNum` to the appropriate values. See the descriptions of [VFSAnyMountParamType](#), [VFSSlotMountParamType](#), and [VFSPOSEMountParamType](#) for information on the fields that make up these data structures.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error.
<code>expErrNotEnoughPower</code>	There is insufficient battery power to mount a volume.
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>sysErrParamErr</code>	<code>vfsMountParamP</code> was initialized to <code>NULL</code> .
<code>vfsErrNoFileSystem</code>	The VFS Manager cannot find an appropriate file system to handle the request.
<code>vfsErrVolumeStillMounted</code>	The volume is already mounted with a different file system than was specified in <code>fsLibRefNum</code> .

**Comments** The slot driver only supports one volume per slot. The reference number of the mounted volume is returned in `vfsMountParamP->volRefNum`. If `vfsMountFlagsUseThisFileSystem` is passed

as a flag, `VFSVolumeMount` attempts to mount the volume using the file system library specified by `fsLibRefNum`. Otherwise `VFSVolumeMount` tries to find a file system library which is able to mount the volume. If none of the installed file system libraries is able to mount the volume, `VFSVolumeMount` attempts to re-format the volume (using [VFSVolumeFormat](#)) and then mount it. If `VFSVolumeMount` manages to successfully mount the volume, it ends by posting a [sysNotifyVolumeMountedEvent](#) notification.

After `VFSVolumeMount` successfully mounts a volume, it broadcasts `sysNotifyVolumeMountedEvent`. The VFS Manager, upon being notified of this event, searches the newly-mounted volume for `/PALM/start.prc`. If `start.prc` is found in the `/PALM` directory, the VFS Manager copies it to main memory and launches it. If `start.prc` is not found, the VFS Manager switches to the Launcher instead. This behavior can be overridden; see [Card Insertion and Removal](#) in [Chapter 7, "Expansion," Palm OS Programmer's Companion](#), vol. I.

When `VFSVolumeMount` is called, if the volume is already mounted with a different file system than was specified in `fsLibRefNum`, a `vfsErrVolumeStillMounted` error is returned. If the volume is already mounted with the same file system that is specified in `fsLibRefNum`, or if `vfsMountFlagsUseThisFileSystem` is not set, `VFSVolumeMount` returns `errNone` and sets `volRefNumP` to the reference number of the currently mounted volume.

**Example** The following code excerpt mounts a volume on an Expansion Manager slot using a compatible file system.

---

```
VFSslotMountParamType slotParam ;
UInt32 slotIterator = expIteratorStart;

slotParam.vfsMountParamP.mountClass =
    VFSMountClass_SlotDriver;
err = ExpSlotEnumerate(&slotParam.slotRefNum,
    &slotIterator);
err = ExpSlotLibFind(slotParam.slotRefNum,
    &slotParam.slotLibRefNum);

err = VFSVolumeMount(NULL, NULL,
    (VFSAnyMountParamPtr) & slotParam);
```

---

## Virtual File System Manager

### VFS Manager Functions

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeFormat](#), [VFSVolumeUnmount](#)

## VFSVolumeSetLabel

**Purpose** Changes the volume label for a mounted volume.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeSetLabel(UInt16 volRefNum,  
const Char *labelP)`

**Parameters**

-> volRefNum	Volume reference number returned from <a href="#">VFSVolumeEnumerate</a> .
-> labelP	Pointer to the label to be applied to the specified volume. This string must be null-terminated.

**Result** Returns one of the following error codes:

<code>errNone</code>	No error
<code>expErrNotOpen</code>	The file system library necessary for this call has not been installed or has not been opened.
<code>vfsErrBadName</code>	The supplied label is invalid.
<code>vfsErrNameShortened</code>	Indicates that the label name was too long. A shortened version of the label name was used instead.
<code>vfsErrVolumeBadRef</code>	The specified volume has not been mounted.

**Comments** Volume labels can be up to 255 characters long. They can contain any normal character, including spaces and lower case characters, in any character set as well as the following special characters: \$ % ' - \_ @ ~ ` ! ( ) ^ # & + , ; = [ ]. See [Naming Volumes](#) in [Chapter 7](#),

[“Expansion,”](#) *Palm OS Programmer’s Companion*, vol. I for guidelines on naming.

---

**NOTE:** Most clients should not need to call this function. This function may create or delete a file in the root directory, which would invalidate any current calls to [VFSDirEntryEnumerate](#).

---

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeGetLabel](#)

## VFSVolumeSize

**Purpose** Determine the total amount of space on a volume, as well as the amount that is currently being used.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeSize(UInt16 volRefNum,  
UInt32 *volumeUsedP, UInt32 *volumeTotalP)`

**Parameters**

- > `volRefNum` Volume reference number returned from [VFSVolumeEnumerate](#).
- <- `volumeUsedP` Pointer to a variable that receives the amount of space, in bytes, in use on the volume.
- <- `volumeTotalP` Pointer to a variable that receives the total amount of space on the volume, in bytes.

**Result** Returns one of the following error codes:

- `errNone` No error.
- `expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

## Virtual File System Manager

### VFS Manager Functions

---

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The specified volume has not been mounted.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeInfo](#)

## VFSVolumeUnmount

**Purpose** Unmount the given volume.

**Declared In** `VfsMgr.h`

**Prototype** `Err VFSVolumeUnmount (UInt16 volRefNum)`

**Parameters** `-> volRefNum` Volume reference number returned from [VFSVolumeEnumerate](#).

**Result** Returns one of the following error codes:

`errNone` No error.

`expErrNotOpen` The file system library necessary for this call has not been installed or has not been opened.

`vfsErrNoFileSystem`

The VFS Manager cannot find an appropriate file system to handle the request.

`vfsErrVolumeBadRef`

The specified volume has not been mounted.

**Comments** This function closes any opened files and posts a [sysNotifyVolumeUnmountedEvent](#) notification once the file system is successfully unmounted.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSVolumeMount](#)

## Application-Defined Functions

### VFSExportProcPtr

**Purpose** User-defined callback function supplied to [VFSExportDatabaseToFileCustom](#) that tracks the progress of the export.

**Declared In** `VfsMgr.h`

**Prototype**  

```
typedef Err (*VFSExportProcPtr)
(UINT32 totalBytes, UINT32 offset,
void *userDataP)
```

**Parameters**

<code>totalBytes</code>	The total number of bytes being exported.
<code>offset</code>	Undefined.
<code>userDataP</code>	Pointer to any application-specific data passed to the callback function. This pointer may be NULL if your callback doesn't need any such data.

**Result** Your progress tracker should allow the user to abort the export. Return `errNone` if the export should continue, or any other value to abort the export process. If you return a value other than `errNone`, that value will be returned by [VFSExportDatabaseToFileCustom](#).

**Comments** See the [Progress Dialogs](#) section in the *Palm OS Programmer's Companion*, vol. I for more information on writing a progress tracker.

**Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.

**See Also** [VFSImportProcPtr](#)

## Virtual File System Manager

### Application-Defined Functions

---

## VFSImportProcPtr

- Purpose** User-defined callback function supplied to [VFSImportDatabaseFromFileCustom](#) that tracks the progress of the import.
- Declared In** `VfsMgr.h`
- Prototype**  

```
typedef Err (*VFSImportProcPtr)
(UInt32 totalBytes, UInt32 offset,
void *userDataP)
```
- Parameters**
- |                         |  |
|-------------------------|--|
| <code>totalBytes</code> | The total number of bytes being imported.  |
| <code>offset</code>     | The number of bytes that have already been imported. This value, along with the total number of bytes being imported, allows you to inform the user how far along the import is. |
| <code>userDataP</code>  | Pointer to NY application-specific data passed to the callback function. This pointer may be NULL if your callback doesn't need any such data.                                   |
- Result** Your progress tracker should allow the user to abort the import. Return `errNone` if the import should continue, or any other value to abort the import process. If you return a value other than `errNone`, that value will be returned by [VFSImportDatabaseFromFileCustom](#).
- Comments** See the [Progress Dialogs](#) section in the *Palm OS Programmer's Companion*, vol. I for more information on writing a progress tracker.
- Compatibility** Implemented only if the [VFS Manager Feature Set](#) is present.
- See Also** [VFSExportProcPtr](#)

# Windows

---

This chapter provides information about windows by discussing these topics:

- [Window Data Structures](#)
- [Window Constants](#)
- [Window Functions](#)

No resources are associated with window objects.

The header file `Window.h` declares the API that this chapter describes. For more information on windows, see the section “[Text](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Window Data Structures

### CustomPatternType

The `CustomPatternType` type holds an 8-by-8 bit pattern that is one bit deep. Each byte specifies a row of the pattern. When drawing, a pattern is tiled to fill a specified region. This pattern is used by [WinFillLine](#) and [WinFillRectangle](#).

The [PatternType](#) specifies the name of the current pattern.

```
typedef UInt8 CustomPatternType [8];
```

**Compatibility** In pre-3.5 systems, the `CustomPatternType` is an array of 4 16-bit words. Note the size of this data type has not changed.

### DrawStateType

The `DrawStateType` structure defines the current drawing state, which is the Palm OS® implementation of a **pen**. This drawing state is saved with [WinPushDrawState](#) and restored with [WinPopDrawState](#).

## Windows

### Window Data Structures

---

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `DrawStateType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct DrawStateType {
    WinDrawOperation transferMode;
    PatternType pattern;
    UnderlineModeType underlineMode;
    FontID fontId;
    FontPtr font;
    CustomPatternType patternData;
    IndexedColorType foreColor;
    IndexedColorType backColor;
    IndexedColorType textColor;
    UInt8 reserved;
    RGBColorType foreColorRGB;
    RGBColorType backColorRGB;
    RGBColorType textColorRGB;
    UInt16 coordinateSystem;
    UInt16 reserved2;
    Fixed16 scale;
    Fixed16 ntvToActiveScale;
    Fixed16 stdToActiveScale;
    Fixed16 activeToStdScale;
} DrawStateType;
```

### Field Descriptions

transferMode	The current transfer mode for color drawing. See <a href="#">WinDrawOperation</a> . Use <a href="#">WinSetDrawMode</a> to set this value.
pattern	The name of the current pattern. See <a href="#">PatternType</a> . If set to customPattern, the patternData field contains the actual pattern. Use <a href="#">WinGetPatternType</a> and <a href="#">WinSetPatternType</a> to retrieve and set this value.
underlineMode	The current underline mode. See UnderlineModeType. Use <a href="#">WinSetUnderlineMode</a> to set this value.
fontId	The ID of the current font. Use <a href="#">FntSetFont</a> to set this value.
font	A pointer to the current font. Use <a href="#">FntSetFont</a> to set this value.
patternData	The current pattern being used by the WinFill functions if pattern is customPattern. See <a href="#">CustomPatternType</a> . Use <a href="#">WinGetPattern</a> and <a href="#">WinSetPattern</a> to retrieve and set this value.
foreColor	Index of the current color used for the foreground. Use <a href="#">WinSetForeColor</a> to set this value. This field is only valid for indexed color bitmaps.
backColor	Index of the current color used for the background. Use <a href="#">WinSetBackColor</a> to set this value. This field is only valid for indexed color bitmaps.
textColor	Index of the current color used for text. Use <a href="#">WinSetTextColor</a> to set this value. This field is only valid for indexed color bitmaps.

## Windows

### Window Data Structures

---

<code>reserved</code>	Reserved for future use.
<code>foreColorRGB</code>	RGB value of the current color used for the foreground. Use <a href="#">WinSetForeColorRGB</a> to set this value. This field is only valid for Palm OS 4.0 or later, and only valid for direct color bitmaps.
<code>backColorRGB</code>	RGB value of the current color used for the background. Use <a href="#">WinSetBackColorRGB</a> to set this value. This field is only valid for Palm OS 4.0 or later, and only valid for direct color bitmaps.
<code>textColorRGB</code>	RGB value of the current color used for text. Use <a href="#">WinSetTextColorRGB</a> to set this value. This field is only valid for Palm OS 4.0 or later, and only valid for direct color bitmaps.
<code>coordinateSystem</code>	Active coordinate system.
<code>reserved2</code>	Reserved for future use.
<code>scale</code>	A fixed point value used to convert from the draw window's active coordinate system to native coordinates. This field is defined only if the <a href="#">High-Density Display Feature Set</a> is present.
<code>ntvToActiveScale</code>	A fixed point value used to convert from the native coordinate system to the draw window's active coordinate system. This field is defined only if the <a href="#">High-Density Display Feature Set</a> is present.

`stdToActiveScale` A fixed point value used to convert from the standard coordinate system to the draw window's active coordinate system. This field is used internally to convert font metrics, which are stored as standard coordinates. This field is defined only if the [High-Density Display Feature Set](#) is present.

`activeToStdScale` The inverse of `stdToActive`; the active-to-standard scaling factor. This field is defined only if the [High-Density Display Feature Set](#) is present.

**Compatibility** This type is implemented only if [3.5 New Feature Set](#) is present. The `scale`, `ntvToActiveScale`, `stdToActiveScale`, and `activeToStdScale` fields are defined only if the [High-Density Display Feature Set](#) is present.

## FrameBitsType

The `FrameBitsType` structure specifies attributes of a window's frame.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FrameBitsType` bit field. Never access its bit field members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef union FrameBitsType {
    struct {
        UInt16 cornerDiam    : 8;
        UInt16 reserved_3    : 3;
        UInt16 threeD        : 1;
        UInt16 shadowWidth   : 2;
        UInt16 width         : 2;
    } bits;
    UInt16 word;
} FrameBitsType;
```

## Windows

### Window Data Structures

---

#### Field Descriptions

<code>cornerDiam</code>	Corner radius of frame; maximum is 38.
<code>reserved_3</code>	Reserved.
<code>threeD</code>	Set this bit to draw a 3D button. This feature is not currently supported.
<code>shadowWidth</code>	Width of shadow.
<code>width</code>	Frame width.
<code>word</code>	Reserved.

#### FrameType

The `FrameType` type specifies a window frame style.

```
typedef UInt16 FrameType;
```

The `FrameType` can be set to one of the defined frame types shown in the table below, or a custom frame type as defined by a [FrameBitsType](#) structure.

---

Constant	Value	Description
<code>noFrame</code>	0	No frame
<code>simpleFrame</code>	1	Plain rectangular frame
<code>rectangleFrame</code>	1	Plain rectangular frame
<code>simple3DFrame</code>	0x0012	3D frame with width of 2. This frame type is not supported.
<code>roundFrame</code>	0x0401	Round frame with width of 1.
<code>boldRoundFrame</code>	0x0702	Round frame with width of 2.
<code>popupFrame</code>	0x0205	Popup frame style with slight corner roundness, width of 1 and shadow of 1.
<code>dialogFrame</code>	0x0302	Dialog frame style with slight corner roundness and width of 2.
<code>menuFrame</code>	<code>popupFrame</code>	Same as <code>popupFrame</code> .

---

## IndexedColorType

The `IndexedColorType` type is used to specify a color by its index value; that is, by its location in a color table. Color tables are defined by the [ColorTableType](#) structure, which is declared in `Bitmap.h`. The `IndexedColorType` can hold a 1, 2, 4, or 8-bit index.

```
typedef UInt8 IndexedColorType;
```

**Compatibility** This type is implemented only if [3.5 New Feature Set](#) is present.

## PatternType

The `PatternType` enumerated type specifies a pattern for drawing. This type is returned by [WinGetPatternType](#) and is used as a parameter to the [WinSetPatternType](#) function.

```
typedef enum {
    blackPattern,
    whitePattern,
    grayPattern,
    customPattern,
    lightGrayPattern,
    darkGrayPattern
} PatternType;
```

### Value Descriptions

<code>blackPattern</code>	Pattern with all bits on.
<code>whitePattern</code>	Pattern with all bits off.
<code>grayPattern</code>	Pattern with alternating on and off bits.
<code>customPattern</code>	Custom pattern specified by <a href="#">CustomPatternType</a> .

## Windows

### Window Data Structures

---

- `lightGrayPattern` Pattern with one out of four bits in each row turned on. This value is defined only if the [High-Density Display Feature Set](#) is present.
- `darkGrayPattern` Pattern with one out of four bits in each row turned off. This value is defined only if the [High-Density Display Feature Set](#) is present.

These patterns all operate with current foreground and background color instead of black and white. In effect, `blackPattern` is only black if the current foreground color is black. `whitePattern` uses the current background color. `grayPattern` and `customPattern` uses a combination of background and foreground colors.

Patterns are expanded to the destination bit depth by the blitter when drawing patterned lines and filled rectangles.

The three standard gray patterns—`grayPattern`, `lightGrayPattern`, and `darkGrayPattern`—are always drawn by the blitter using the screen density to improve the appearance of gray fills. Custom patterns, however, are stretched as appropriate by the blitter based on the destination density.

#### Compatibility

The `lightGrayPattern` and `darkGrayPattern` values are defined only if the [High-Density Display Feature Set](#) is present.

### UnderlineModeType

The `UnderlineModeType` enumerated type specifies possible values for the underline mode stored in [DrawStateType](#).

```
typedef enum { noUnderline, grayUnderline,  
solidUnderline, colorUnderline }  
UnderlineModeType;
```

### **Value Descriptions**

noUnderline	No underline.
grayUnderline	Underline is drawn using a dotted line in the current foreground color.
solidUnderline	Underline is drawn using a solid line in the foreground color.
colorUnderline	Underline is drawn using a solid line in the foreground color.

**Compatibility** The `solidUnderline` and `colorUnderline` options are only available in Palm OS 3.1 and higher.

### **WindowFlagsType**

The `WindowFlagsType` specifies different window attributes.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `WindowFlagsType` bit field. Access it only through the functions described below. Never access its bit field members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct WindowFlagsType {  
    UInt16 format:1;  
    UInt16 offscreen:1;  
    UInt16 modal:1;  
    UInt16 focusable:1;  
    UInt16 enabled:1;  
    UInt16 visible:1;  
    UInt16 dialog:1;  
    UInt16 freeBitmap:1;
```

## Windows

### Window Data Structures

---

```
    UInt16 reserved :8;
} WindowFlagsType;
```

#### Field Descriptions

<code>format</code>	If set, use the <code>genericFormat</code> . If 0, use <code>screenFormat</code> . Screen format is the native format of the video system; windows in this format can be copied to the display faster. The generic format is device-independent. A window cannot be enabled (that is, accept pen input) unless it uses screen format.
<code>offscreen</code>	If set, the window is offscreen. If 0, the window is onscreen.
<code>modal</code>	If set, the window is modal. If 0, the window is not modal. You set this value when you create the window. This value is returned by <a href="#">WinModal</a> .
<code>focusable</code>	If set, the window can accept the focus. If 0, the window does not accept the focus. You set this value when you create the window.
<code>enabled</code>	If set, the window is enabled. If 0, the window is disabled.
<code>visible</code>	If set, the window is visible if it is onscreen. If 0, the window is not visible.
<code>dialog</code>	If set, the window is a form. If 0, the window is not a form. The <a href="#">FrmInitForm</a> function sets this value.
<code>freeBitmap</code>	If set, free the bitmap when the window is freed. If 0, retain the bitmap after the window is freed.
<code>reserved</code>	Reserved for future use. Must be 0.

#### Compatibility

In OS versions previous to 3.5, the `freeBitmap` flag was not present. Instead, a compressed flag was present, where 0 specified uncompressed and 1 specified compressed. This compressed flag is now part of the [BitmapType](#).

## WindowFormatType

Use this enumeration to specify the window format when creating an offscreen window with the [WinCreateOffscreenWindow](#) function.

```
typedef enum {
    screenFormat = 0,
    genericFormat,
    nativeFormat
} WindowFormatType;
```

### Field Values

- `screenFormat` The window's bitmap is allocated using the hardware screen's depth, but for backward compatibility the bitmap associated with the offscreen window is always low density, and the window always uses a coordinate system that directly maps offscreen pixels to coordinates.
- `genericFormat` Like `screenFormat`, except that `genericFormat` offscreen windows do not accept pen input.
- `nativeFormat` Reflects the actual hardware screen format in all ways, including screen depth, density, and pixel format. Applications must always use the graphic API when drawing to a `nativeFormat` offscreen window: directly accessing offscreen pixels will produce undefined results. When using this format, the width and height arguments must be specified using the active coordinate system. Like `genericFormat`, `nativeFormat` offscreen windows do not accept pen input.

**Compatibility** `WindowFormatType` is defined only if the [High-Density Display Feature Set](#) is present.

## WindowType

The `WindowType` structure represents a window.

## Windows

### Window Data Structures

---

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `WindowType` structure. Access it only through the functions described below. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct WindowType {
    Coord          displayWidthV20;
    Coord          displayHeightV20;
    void          *displayAddrV20;
    WindowFlagsType windowFlags;
    RectangleType windowBounds;
    AbsRectType   clippingBounds;
    BitmapPtr     bitmapP;
    FrameBitsType frameType;
    DrawStateType *drawStateP;
    struct WindowType *nextWindow;
} WindowType;
```

#### Field Descriptions

- `displayWidthV20` Width of the window in pre OS 3.5 devices. In OS 3.5, use [WinGetBounds](#) to return the window width.
- `displayHeightV20` Height of the window in pre OS 3.5 devices. In OS 3.5, use [WinGetBounds](#) to return the window height.
- `displayAddrV20` Pointer to the window display memory buffer in pre OS 3.5 devices. In OS 3.5 or later, call [WinGetBitmap](#) and then [BmpGetBits](#) to obtain the window's memory buffer.

---

**WARNING!** Writing directly to screen memory will not be supported in all devices.

---

- `windowFlags` Window attributes (see [WindowFlagsType](#)).

windowBounds	Display-relative bounds of the window. Use <a href="#">WinGetBounds</a> and <a href="#">WinSetBounds</a> to retrieve and set this value.
clippingBounds	Bounds for clipping any drawing within the window. Use <a href="#">WinGetClip</a> and <a href="#">WinSetClip</a> to retrieve and set this value.
bitmapP	Pointer to the window bitmap, which holds the window's contents. Use <a href="#">WinGetBitmap</a> to retrieve this value.
frameType	Frame attributes; see <a href="#">FrameBitsType</a> .
drawStateP	Pointer to a state of the current transfer mode, pattern mode, font, underline mode, and colors. See <a href="#">DrawStateType</a> . Only one drawing state exists in the system. Each window points to the same structure.
nextWindow	Pointer to the next window in a linked list of windows. This linked list of windows is called the active window list. Do not change this field.

**Compatibility** In OS versions previous to 3.5, this structure is slightly different. Specifically, the `bitmapP` field is instead a `viewOrigin` field of type `PointType` and specified the window origin point on the display. The `drawStateP` was named `gstate` and was of type `GraphicStatePtr`. The complete definition is shown below:

```
typedef struct WinTypeStruct {
    Word          displayWidth;
    Word          displayHeight;
    VoidPtr       displayAddr;
    WindowFlagsType windowFlags;
    RectangleType windowBounds;
    AbsRectType   clippingBounds;
    PointType     viewOrigin;
    FrameBitsType frameType;
    GraphicStatePtr gstate;
    struct WinTypeStruct *nextWindow;
}
```

## Windows

### Window Data Structures

---

```
} WindowType;
```

## WinDrawOperation

The WinDrawOperation enumerated type specifies the transfer mode for color drawing. This type is used as a parameter to the [WinCopyRectangle](#) and [WinSetDrawMode](#) functions.

```
typedef enum {winPaint, winErase, winMask,  
winInvert, winOverlay, winPaintInverse,  
winSwap} WinDrawOperation;
```

### Value Descriptions

winPaint	Write color-matched source pixels to the destination. If a bitmap's <code>hasTransparency</code> flag is set, <code>winPaint</code> behaves like <code>winOverlay</code> instead.
winErase	Write <code>backColor</code> if the source pixel is transparent.
winMask	Write <code>backColor</code> if the source pixel is not transparent.
winInvert	Bitwise XOR the color-matched source pixel onto the destination. This mode does not honor the transparent color in any way.
winOverlay	Write color-matched source pixel to the destination if the source pixel is not transparent. Transparent pixels are skipped. For a 1-bit display, the "off" bits are considered to be the transparent color. Note that this definition of <code>winOverlay</code> is new for Palm OS 5: in Palm OS 4.x, the destination is set (only) where the source pixels are "on."

<code>winPaintInverse</code>	Invert the source pixel color and then proceed as with <code>winPaint</code> .
<code>winSwap</code>	Swap the <code>backColor</code> and <code>foreColor</code> destination colors if the source is a pattern (the type of pattern is disregarded). If the source is a bitmap, then the bitmap is transferred using <code>winPaint</code> mode instead.

Note that 2-bit, 4-bit, and 8-bit source bitmaps that don't have a color table inherit the system default color table for their given depth. 1-bit sources (bitmap, text, and patterns) that don't have a color table are given a color table where entry 0 is the `backColor` and entry 1 is the `foreColor` (`textColor` for text).

`winSwap` is not a color invert operation, although a pair of `winSwap` operations will restore the original graphics data. This mode is used by the OS to select and deselect areas of the screen. It changes destination pixels matching the foreground color to the background color, and changes destination pixels matching the background color to the foreground color. It is a mode available for rectangles, lines, and pixels, but not text or bitmaps. This mode ignores the current pattern. **The Transparent Color**

As of Palm OS 4.0, bitmaps have a `hasTransparency` flag and may designate a transparent color. These concepts are augmented somewhat in Palm OS 5 to make the transfer modes more consistent:

- Bitmaps that don't specify any transparent color (text, patterns, and version 0 bitmaps) are assumed to have a transparent color of index 0 and the `hasTransparency` bit is assumed to be `false`.
- When the `hasTransparency` flag is set and the transfer mode is `winPaint`, only the non-transparent pixels are copied to the destination. With text and patterns, the Palm OS assumes that the "off" bits are the ones designated as transparent and acts as if the `hasTransparency` flag is always `false`. This assumption retains backwards compatibility and unifies the use of transparency across all source data.

## Windows

### Window Data Structures

---

**Compatibility** This type is implemented only if [3.5 New Feature Set](#) is present. In earlier releases, this type is named `ScrOperation` and its values begin with the prefix `scr` rather than `win`. `WinDrawOperation` is fully compatible with `ScrOperation`. Transparency is only available if [4.0 New Feature Set](#) is present, and as mentioned in [“winSwap is not a color invert operation, although a pair of winSwap operations will restore the original graphics data. This mode is used by the OS to select and deselect areas of the screen. It changes destination pixels matching the foreground color to the background color, and changes destination pixels matching the background color to the foreground color. It is a mode available for rectangles, lines, and pixels, but not text or bitmaps. This mode ignores the current pattern. The Transparent Color”](#) the behavior of the window drawing modes—`winOverlay` in particular—changes slightly if [5.0 New Feature Set](#) is present.

## WinHandle

The `WinHandle` type is a pointer to a [WindowType](#) structure. Note that this may change.

```
typedef WindowType *WinHandle;
```

## WinLineType

The `WinLineType` structure defines a line.

```
typedef struct WinLineType {
    Coord x1;
    Coord y1;
    Coord x2;
    Coord y2;
} WinLineType;
```

### Field Descriptions

<code>x1</code>	X coordinate of the first endpoint of the line.
<code>y1</code>	Y coordinate of the first endpoint of the line.
<code>x2</code>	X coordinate of the second endpoint of the line.
<code>y2</code>	Y coordinate of the second endpoint of the line.

**Compatibility** This type is implemented only if [3.5 New Feature Set](#) is present.

## WinPtr

The WinPtr type is a pointer to a [WindowType](#) structure.

```
typedef WindowType *WinPtr;
```

## Window Constants

If the [5.0 New Feature Set](#) or the [High-Density Display Feature Set](#) are present, the following constants are defined:

- [Window Coordinate System Constants](#)

---

### **New** Window Coordinate System Constants

These constants specify the coordinate system to be used when drawing within a given window:

---

Constant	Value	Description
kCoordinatesNative	0	Use the bitmap's native coordinate system; this enables a 1-to-1 correspondence between coordinates and pixels.
kCoordinatesStandard	72	The coordinate system used by most handhelds running Palm OS 4.0 and earlier. On a single-density handheld, there is one screen pixel per standard coordinate. On a high-density screen, there is more than one screen pixel per standard coordinate.
kCoordinatesOneAndAHalf	108	One and a half times the standard coordinate system.
kCoordinatesDouble	144	Twice the standard coordinate system.
kCoordinatesTriple	216	Three times the standard coordinate system.
kCoordinatesQuadruple	288	Four times the standard coordinate system.

---

## Windows

### Window Functions

---

---

**IMPORTANT:** Not all coordinate systems listed in the above table are supported in this version of the [High-Density Display Feature Set](#). For Palm OS 5, only `kCoordinatesNative`, `kCoordinatesStandard`, and `kCoordinatesDouble` are supported.

---

Pass one of these constants as an argument to [WinSetCoordinateSystem](#). These values are returned by [WinGetCoordinateSystem](#).

**Compatibility** Defined only if the [High-Density Display Feature Set](#) is present.

## Window Functions

### WinClipRectangle

<b>Purpose</b>	Shrink the rectangle to make it fit within the clipping region of the current draw window.
<b>Declared In</b>	<code>Window.h</code>
<b>Prototype</b>	<code>void WinClipRectangle (RectangleType *rP)</code>
<b>Parameters</b>	<code>&lt;-&gt; rP</code> Pointer to a structure holding the rectangle to clip. The rectangle returned is the intersection of the rectangle passed and the clipping bounds of the draw window.
<b>Result</b>	Returns nothing.
<b>Comments</b>	This function does not change the clipping rectangle of the window. To modify the window's clipping rectangle, use the <a href="#">WinSetClip</a> and <a href="#">WinResetClip</a> functions.

The draw window is the window to which all drawing functions send their output. It is returned by [WinGetDrawWindow](#).

**See Also** [WinCopyRectangle](#), [WinDrawRectangle](#),  
[WinEraseRectangle](#), [WinGetClip](#)

## WinCopyRectangle

**Purpose** Copy a rectangular region from one place to another (either between windows or within a single window).

**Declared In** Window.h

**Prototype** `void WinCopyRectangle (WinHandle srcWin,  
WinHandle dstWin, const RectangleType *srcRect,  
Coord destX, Coord destY, WinDrawOperation mode)`

**Parameters**

-> srcWin	Window from which the rectangle is copied. If NULL, use the draw window.
-> dstWin	Window to which the rectangle is copied. If NULL, use the draw window.
-> srcRect	Bounds of the region to copy.
-> destX	Top bound of the rectangle in destination window.
-> destY	Left bound of the rectangle in destination window.
-> mode	The method of transfer from the source to the destination window (see <a href="#">WinDrawOperation</a> ).

**Result** Returns nothing.

**Comments** Copies the bits of the window inside the rectangle region. If the destination bitmap is compressed, the mode parameter must be winPaint, and the destination coordinates must be (0,0). If the width of the destination rectangle is less than 16 pixels or if the

## Windows

### Window Functions

---

destination coordinates are not (0,0), then this function turns off compression for the destination bitmap. Normally, you do not copy to a compressed bitmap. Instead, you copy to an uncompressed bitmap and compress it afterwards.

**Compatibility** In OS versions before 3.5, the mode parameter was defined as type `ScrOperation`. It is defined as type `WinDrawOperation` only if [3.5 New Feature Set](#) is present. `ScrOperation` and `WinDrawOperation` are fully compatible with each other.

In OS versions before 3.5, it was common practice to render a bitmap in an offscreen window and then use `WinCopyRectangle` to draw it on the screen. In version 3.5 and higher, the preferred method of doing this is to use [WinDrawBitmap](#) or [WinPaintBitmap](#).

**See Also** [WinDrawBitmap](#)

## WinCreateBitmapWindow

**Purpose** Create a new offscreen window.

**Declared In** `Window.h`

**Prototype** `WinHandle WinCreateBitmapWindow  
(BitmapType *bitmapP, UInt16 *error)`

**Parameters**

<code>-&gt; bitmapP</code>	Pointer to a bitmap to associate with the window. (See <a href="#">BitmapType</a> .)
<code>&lt;- error</code>	Pointer to any error this function encounters.

**Result** Returns the handle of the new window upon success, or `NULL` if an error occurs. The error parameter contains one of the following:

<code>errNone</code>	No error.
<code>sysErrParamErr</code>	The <code>bitmapP</code> parameter is invalid. The bitmap must be uncompressed and it must have a valid pixel size (1, 2, 4, or 8). It must not be the screen bitmap.

sysErrNoFreeResource

There is not enough memory to allocate a new window structure.

**Comments** Use `WinCreateBitmapWindow` if you want to draw into a previously created bitmap, such as a bitmap created using [BmpCreate](#).

This function generates a window wrapper for the specified bitmap. The newly created window is offscreen, uses the generic format (for device independence), and is added to the active window list. Use [WinSetDrawWindow](#) to make it the draw window, and then use the window drawing functions to modify the bitmap.

When you use this function to create a window and then delete the window with [WinDeleteWindow](#), the bitmap is **not** freed when the window is freed.

[WinCreateOffscreenWindow](#) uses this function to create its offscreen window. If you call `WinCreateOffscreenWindow` instead of using this function, the bitmap is freed when `WinDeleteWindow` is called.

The bitmap data will not be blitted properly if the depth of the screen is changed using [WinScreenMode](#) and the new window uses a bitmap that does not define the bitmap's color table. See [WinScreenMode](#) for information on how to work around this limitation.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinCreateWindow](#), [WinCreateOffscreenWindow](#)

## WinCreateOffscreenWindow

- Purpose** Create a new offscreen window and add it to the window list.
- Declared In** Window.h
- Prototype** WinHandle WinCreateOffscreenWindow (Coord width, Coord height, WindowFormatType format, UInt16 \*error)
- Parameters**
- > width Width of the window in pixels. The coordinate system you use for this parameter depends upon the value of format.
  - > height Height of the window in pixels. The coordinate system you use for this parameter depends upon the value of format.
  - > format One of the window formats defined by [WindowFormatType](#).
  - <- error Pointer to any error this function encounters.
- Result** Returns the handle of the new window upon success, or NULL if an error occurs. The error parameter contains one of the following:
- errNone No error.
  - sysErrParamErr The width or height parameter is NULL or the current color table is invalid.
  - sysErrNoFreeResource There is not enough memory to complete the function.
- The debug ROM gives a warning if you try to draw to a bad window address.
- Comments** Windows created with this routine draw to a memory buffer instead of the display. Use this function for temporary drawing operations such as double-buffering or save-behind operations.
- The memory buffer has two formats: screen format and generic format. Screen format is the native format of the video system;

windows in this format can be copied to the display faster. The generic format is device-independent. A window cannot be enabled (that is, accept pen input) unless it uses screen format.

This function differs from [WinCreateBitmapWindow](#) in the following ways:

- `WinCreateOffscreenWindow` creates a new bitmap in the same depth as the current screen. `WinCreateBitmapWindow` uses the bitmap you pass in, which may or may not be in the same depth as the current screen.
- `WinCreateOffscreenWindow` uses the screen format you specify. `WinCreateBitmapWindow` always uses `genericFormat` for the format argument.
- When you delete the window created with `WinCreateOffscreenWindow`, its bitmap is freed along with the window. The bitmap used in the `WinCreateBitmapWindow` is not freed when the window is freed.

Note that if you aren't directly accessing the bits of an offscreen window's bitmap but are just using the APIs, you can always pass `nativeFormat` for the screen format even on pre-Palm OS 5 handhelds and things will work as expected. If you need direct access to the bits of the offscreen window's bitmap, however, call [BmpCreate](#) and then call `WinCreateBitmapWindow`. Because you created the bitmap, you know its format and thus can safely manipulate its bits. Calling `WinCreateOffscreenWindow` with a format argument of `nativeFormat` can result in a bitmap with an unexpected format: the endianness, number of bits per pixel, and so on would match the screen and therefore be fastest to draw, but your application wouldn't be able to manipulate the pixels directly.

The bitmap data will not be blitted properly if the depth of the screen is changed using [WinScreenMode](#) and the new window uses a bitmap that does not define the bitmap's color table. See [WinScreenMode](#) for information on how to work around this limitation.

**See Also** [WinCreateWindow](#), [WinScreenMode](#),

## Windows

### Window Functions

---

## WinCreateWindow

<b>Purpose</b>	Create a new window and add it to the window list.
<b>Declared In</b>	Window.h
<b>Prototype</b>	WinHandle WinCreateWindow (const RectangleType *bounds, FrameType frame, Boolean modal, Boolean focusable, UInt16 *error)
<b>Parameters</b>	-> bounds            Display-relative bounds of the window. -> frame            Type of frame around the window (see <a href="#">FrameType</a> ). -> modal            true if the window is modal. -> focusable        true if the window can be the active window. <- error            Pointer to any error encountered by this function.
<b>Result</b>	Returns the handle of the new window upon success, or NULL if an error occurs. The error parameter contains one of the following:  errNone            No error.  sysErrNoFreeResource        There is not enough memory to complete the operation.
<b>Comments</b>	Windows created by this routine draw to the display. See <a href="#">WinCreateOffscreenWindow</a> for information on drawing off screen.  You typically don't call this function directly. Instead, you use <a href="#">FrmInitForm</a> to create form windows from a resource. Forms are much more flexible and have better system support. All forms are windows, but not all windows are forms.  The window is created with the bounds and frame type that you specify and uses the bitmap and drawing state of the current draw window. Its clipping region is reset according to the bounds you specify.

All window flags are set to 0 except for the modal and focusable flags, which you pass as a parameter to this function. Specifically, newly created windows are disabled and invisible. You must specifically enable the window before the window can accept input. You can do so with [WinSetActiveWindow](#).

**See Also** [WinDeleteWindow](#)

## WinDeleteWindow

**Purpose** Remove a window from the window list and free the memory used by the window.

**Declared In** `Window.h`

**Prototype** `void WinDeleteWindow (WinHandle winHandle, Boolean eraseIt)`

**Parameters**

-> winHandle	Handle of window to delete.
-> eraseIt	If true, the window is erased before it is deleted. If false, the window is not erased.

**Result** Returns nothing.

**Comments** This function frees all memory associated with the window. Windows created using [WinCreateOffscreenWindow](#) have their bitmaps freed; windows created using [WinCreateWindow](#) or [WinCreateBitmapWindow](#) do not.

The `eraseIt` parameter affects onscreen windows only; offscreen windows are never erased. As a performance optimization, you might set `eraseIt` to `false` for an onscreen window if you know that you are going to immediately redraw the area anyway. For example, when the form manager closes a form dialog, it restores the area with the save-behind bits it had stored for that form. For this reason, when the form manager deletes the dialog window, it passes `false` for `eraseIt` because the entire area will be redrawn.

## **WinDisplayToWindowPt**

- Purpose** Convert a display-relative coordinate to a window-relative coordinate. The coordinate returned is relative to the display window.
- Declared In** `Window.h`
- Prototype** `void WinDisplayToWindowPt (Coord *extentX, Coord *extentY)`
- Parameters**
- `<-> extentX`      Pointer to x coordinate to convert.
  - `<-> extentY`      Pointer to y coordinate to convert.
- Result** Returns nothing.
- See Also** [WinWindowToDisplayPt](#)

## **WinDrawBitmap**

- Purpose** Draw a bitmap at the given coordinates in `winPaint` mode (see [WinDrawOperation](#) for mode details).
- Declared In** `Window.h`
- Prototype** `void WinDrawBitmap (BitmapPtr bitmapP, Coord x, Coord y)`
- Parameters**
- `-> bitmapP`      Pointer to a bitmap.
  - `-> x`              The x coordinate of the top-left corner.
  - `-> y`              The y coordinate of the top-left corner.
- Result** Returns nothing.
- Comments** If the bitmap has multiple depths (is a bitmap family), the closest match less than or equal to the current draw window depth is used.

If such a bitmap does not exist, the bitmap with the closest match greater than the draw window depth is used.

If the bitmap has its own color table, color conversion to the draw window color table will be applied (on OS 3.5 or later). This color conversion is slow and not recommended. Instead of including a color table in the bitmap, consider using [WinPalette](#) to change the system color table, draw the bitmap, and then change the system color table back when the bitmap is no longer visible.

This function differs from [WinPaintBitmap](#) in that this function always uses winPaint mode (copy mode) as the transfer mode. WinPaintBitmap uses the current drawing state transfer mode.

**See Also** [WinEraseRectangle](#)

## WinDrawChar

**Purpose** Draw the specified character in the draw window.

**Declared In** Window.h

**Prototype** void WinDrawChar (WChar theChar, Coord x,  
Coord y)

**Parameters**

-> theChar	The character to draw. This may be either a single-byte character or a multi-byte character.
-> x	x coordinate of the location where the character is to be drawn (left bound).
-> y	y coordinate of the location where the character is to be drawn (top bound).

**Result** Returns nothing.

**Comments** Before calling this function, call [WinSetUnderlineMode](#) and [FntSetFont](#) to set the desired underline and font to draw the characters.

This function differs from [WinPaintChar](#) in that this function always uses winPaint mode (see [WinDrawOperation](#)). This

## Windows

### Window Functions

---

means the on bits are drawn in the text color, the off bits are in the background color, and underlines are in the foreground color. `WinPaintChar` uses the current drawing state transfer mode instead of `winPaint`.

**Compatibility** Implemented only if [3.1 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `WinGlueDrawChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [WinDrawChars](#), [WinDrawInvertedChars](#), [WinDrawTruncChars](#), [WinEraseChars](#), [WinInvertChars](#), [WinPaintChars](#)

## WinDrawChars

**Purpose** Draw the specified characters in the draw window.

**Declared In** `Window.h`

**Prototype** `void WinDrawChars (const Char *chars, Int16 len, Coord x, Coord y)`

**Parameters**

-> <code>chars</code>	Pointer to the characters to draw.
-> <code>len</code>	Length in bytes of the characters to draw.
-> <code>x</code>	x coordinate of the first character to draw (left bound).
-> <code>y</code>	y coordinate of the first character to draw (top bound).

**Result** Returns nothing.

**Comments** This function is useful for printing non-editable status or warning messages on the screen.

Before calling this function, call [WinSetUnderlineMode](#) and [FntSetFont](#) to set the desired underline and font to draw the characters.

This function differs from [WinPaintChars](#) in that this function always uses winPaint mode (see [WinDrawOperation](#)). This means the on bits are drawn in the text color, the off bits are in the background color, and underlines are in the foreground color. WinPaintChar uses the current drawing state transfer mode instead of winPaint.

**See Also** [WinDrawChar](#), [WinDrawInvertedChars](#),  
[WinDrawTruncChars](#), [WinEraseChars](#), [WinInvertChars](#),  
[WinPaintChar](#)

## WinDrawGrayLine

**Purpose** Draw a dashed line in the draw window.

**Declared In** Window.h

**Prototype** void WinDrawGrayLine (Coord x1, Coord y1,  
Coord x2, Coord y2)

**Parameters**

-> x1	x coordinate of line start point.
-> y1	y coordinate of line start point.
-> x2	x coordinate of line endpoint.
-> y2	y coordinate of line endpoint.

**Result** Returns nothing.

**Comments** This routine does not draw in the gray color; it draws with alternating foreground and background pixels. That is, it uses the grayPattern pattern type.

**See Also** [WinDrawLine](#), [WinEraseLine](#), [WinFillLine](#), [WinInvertLine](#),  
[WinPaintLine](#), [WinPaintLines](#)

## WinDrawGrayRectangleFrame

- Purpose** Draw a gray rectangular frame in the draw window.
- Declared In** `Window.h`
- Prototype**  
`void WinDrawGrayRectangleFrame (FrameType frame,  
const RectangleType *rP)`
- Parameters**
- > `frame`           Type of frame to draw (see [FrameType](#)).
  - > `rP`                Pointer to the rectangle to frame.
- Result** Returns nothing.
- Comments** This routine does not draw in the gray color; it draws with alternating foreground and background pixels. The standard gray pattern is not used by this routine; rather, the frame is drawn so that the top-left pixel of the frame is always on.
- See Also** [WinDrawRectangleFrame](#), [WinEraseRectangleFrame](#), [WinGetFramesRectangle](#), [WinInvertRectangleFrame](#), [WinPaintRectangleFrame](#)

## WinDrawInvertedChars

- Purpose** Draw the specified characters inverted (background color) in the draw window.
- Declared In** `Window.h`
- Prototype**  
`void WinDrawInvertedChars (const Char *chars,  
Int16 len, Coord x, Coord y)`
- Parameters**
- > `chars`            Pointer to the characters to draw.
  - > `len`              Length in bytes of the characters to draw.
  - > `x`                 x coordinate of the first character to draw (left bound).

-> y                    y coordinate of the first character to draw (top bound).

**Result**            Returns nothing.

**Comments**        This routine draws the **on** bits and any underline in the background color and the **off** bits in the text color. (Black and white uses copy NOT mode.) This is the standard function for drawing inverted text. Before calling this function, consider calling [WinSetUnderlineMode](#) and [FntSetFont](#).

**See Also**        [WinDrawChar](#), [WinDrawChars](#), [WinDrawTruncChars](#), [WinEraseChars](#), [WinInvertChars](#), [WinPaintChar](#), [WinPaintChars](#)

## WinDrawLine

**Purpose**            Draw a line in the draw window using the current foreground color.

**Declared In**      Window.h

**Prototype**        void WinDrawLine (Coord x1, Coord y1, Coord x2, Coord y2)

**Parameters**      -> x1                    x coordinate of line start point.  
                     -> y1                    y coordinate of line start point.  
                     -> x2                    x coordinate of line endpoint.  
                     -> y2                    y coordinate of line endpoint.

**Result**            Returns nothing.

**Comments**        This function differs from [WinPaintLine](#) in that it always uses winPaint mode (see [WinDrawOperation](#)). WinPaintLine uses the current drawing state transfer mode instead of winPaint.

**See Also**        [WinDrawGrayLine](#), [WinEraseLine](#), [WinFillLine](#), [WinInvertLine](#), [WinPaintLine](#), [WinPaintLines](#)

## WinDrawPixel

- Purpose** Draw a pixel in the draw window using the current foreground color.
- Declared In** Window.h
- Prototype** void WinDrawPixel (Coord x, Coord y)
- Parameters**
- > x Pointer to the x coordinate of a pixel.
  - > y Pointer to the y coordinate of a pixel.
- Result** Returns nothing. May display a fatal error message if the draw window's bitmap is compressed.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [WinErasePixel](#), [WinInvertPixel](#), [WinPaintPixel](#), [WinPaintPixels](#)

## WinDrawRectangle

- Purpose** Draw a rectangle in the draw window using the current foreground color.
- Declared In** Window.h
- Prototype** void WinDrawRectangle (const RectangleType \*rP, UInt16 cornerDiam)
- Parameters**
- > rP Pointer to the rectangle to draw.
  - > cornerDiam Radius of rounded corners. Specify zero for square corners.
- Result** Returns nothing.

**Comments** The `cornerDiam` parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides. This function differs from [WinPaintRectangle](#) in that it always uses `winPaint` mode (see [WinDrawOperation](#)). [WinPaintRectangle](#) uses the current drawing state transfer mode instead of `winPaint`.

**See Also** [WinEraseRectangle](#), [WinFillRectangle](#), [WinInvertRectangle](#)

## WinDrawRectangleFrame

**Purpose** Draw a rectangular frame in the draw window using the current foreground color.

**Declared In** `Window.h`

**Prototype** `void WinDrawRectangleFrame (FrameType frame, const RectangleType *rP)`

**Parameters**

- > `frame`           Type of frame to draw (see [FrameType](#)).
- > `rP`                Pointer to the rectangle to frame.

**Result** Returns nothing.

**Comments** The frame is drawn outside the specified rectangle. This function differs from [WinPaintRectangleFrame](#) in that it always uses `winPaint` mode (see [WinDrawOperation](#)). [WinPaintRectangleFrame](#) uses the current drawing state transfer mode instead of `winPaint`.

**See Also** [WinDrawGrayRectangleFrame](#), [WinEraseRectangleFrame](#), [WinGetFramesRectangle](#), [WinInvertRectangleFrame](#)

## WinDrawTruncChars

**Purpose** Draw the specified characters in the draw window, truncating the characters to the specified width.

**Declared In** Window.h

**Prototype** void WinDrawTruncChars (const Char \*chars,  
Int16 len, Coord x, Coord y, Coord maxWidth)

**Parameters**

-> chars	Pointer to the characters to draw.
-> len	Length in bytes of the characters to draw.
-> x	x coordinate of the first character to draw (left bound).
-> y	y coordinate of the first character to draw (top bound).
-> maxWidth	Maximum width in pixels of the characters that are to be drawn.

**Result** Returns nothing.

**Comments** Before calling this function, consider calling [WinSetUnderlineMode](#) and [FntSetFont](#).

If drawing all of the specified characters requires more space than `maxWidth` allows, `WinDrawTruncChars` draws one less than the number of characters that can fit in `maxWidth` and then draws an ellipsis (...) in the remaining space. (If the boundary characters are narrower than the ellipsis, more than one character may be dropped to make room.) If `maxWidth` is narrower than the width of an ellipsis, nothing is drawn.

Use this function to truncate text that may contain multi-byte characters.

**Compatibility** Implemented only if [3.1 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call

WinGlueDrawTruncChars. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [WinDrawChar](#), [WinDrawChars](#), [WinDrawInvertedChars](#), [WinEraseChars](#), [WinInvertChars](#), [WinPaintChar](#), [WinPaintChars](#)

## WinEraseChars

**Purpose** Erase the specified characters in the draw window.

**Declared In** Window.h

**Prototype** void WinEraseChars (const Char \*chars, Int16 len, Coord x, Coord y)

**Parameters**

-> chars	Pointer to the characters to erase.
-> len	Length in bytes of the characters to erase.
-> x	x coordinate of the first character to erase (left bound).
-> y	y coordinate of the first character to erase (top bound).

**Result** Returns nothing.

**Comments** The winMask transfer mode is used to erase the characters. See [WinDrawOperation](#) for more information. This has the effect of erasing only the on bits for the characters rather than the entire text rectangle. This function only works if the foreground color is black and the background color is white.

**See Also** [WinDrawChar](#), [WinDrawChars](#), [WinDrawInvertedChars](#), [WinDrawTruncChars](#), [WinInvertChars](#), [WinPaintChar](#), [WinPaintChars](#)

## WinEraseLine

- Purpose** Draw a line in the draw window using the current background color.
- Declared In** Window.h
- Prototype** void WinEraseLine (Coord x1, Coord y1, Coord x2, Coord y2)
- Parameters**
- > x1 x coordinate of line start point.
  - > y1 y coordinate of line start point.
  - > x2 x coordinate of line endpoint.
  - > y2 y coordinate of line endpoint.
- Result** Returns nothing.
- See Also** [WinDrawGrayLine](#), [WinDrawLine](#), [WinFillLine](#), [WinInvertLine](#), [WinPaintLine](#), [WinPaintLines](#)

## WinErasePixel

- Purpose** Draw a pixel in the draw window using the current background color.
- Declared In** Window.h
- Prototype** void WinErasePixel (Coord x, Coord y)
- Parameters**
- > x Pointer to the x coordinate of a pixel.
  - > y Pointer to the y coordinate of a pixel.
- Result** Returns nothing.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

**See Also**        [WinDrawPixel](#), [WinInvertPixel](#), [WinPaintPixel](#),  
[WinPaintPixels](#)

## WinEraseRectangle

**Purpose**            Draw a rectangle in the draw window using the current background color.

**Declared In**      Window.h

**Prototype**        void WinEraseRectangle (const RectangleType \*rP,  
                          UInt16 cornerDiam)

**Parameters**        -> rP                    Pointer to the rectangle to erase.  
                      -> cornerDiam    Radius of rounded corners. Specify zero for square corners.

**Result**            Returns nothing.

**Comments**        The cornerDiam parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides.

**See Also**        [WinDrawRectangle](#), [WinFillRectangle](#),  
[WinInvertRectangle](#), [WinPaintRectangle](#)

## Windows

### Window Functions

---

## WinEraseRectangleFrame

- Purpose** Draw a rectangular frame in the draw window using the current background color.
- Declared In** Window.h
- Prototype** void WinEraseRectangleFrame (FrameType frame, const RectangleType \*rP)
- Parameters**
- > frame           Type of frame to draw (see [FrameType](#)).
  - > rP                Pointer to the rectangle to frame.
- Result** Returns nothing.
- See Also** [WinDrawGrayRectangleFrame](#), [WinDrawRectangleFrame](#), [WinGetFramesRectangle](#), [WinInvertRectangleFrame](#), [WinPaintRectangleFrame](#)

## WinEraseWindow

- Purpose** Erase the contents of the draw window.
- Declared In** Window.h
- Prototype** void WinEraseWindow (void)
- Parameters** None.
- Result** Returns nothing.
- Comments** [WinEraseRectangle](#) is used to erase the window. This routine doesn't erase the frame around the draw window. See [WinEraseRectangleFrame](#) and [WinGetWindowFrameRect](#).

## WinFillLine

- Purpose** Fill a line in the draw window with the current pattern.
- Declared In** `Window.h`
- Prototype**  
`void WinFillLine (Coord x1, Coord y1, Coord x2,  
Coord y2)`
- Parameters**
- > `x1` x coordinate of line start point.
  - > `y1` y coordinate of line start point.
  - > `x2` x coordinate of line endpoint.
  - > `y2` y coordinate of line endpoint.
- Result** Returns nothing.
- Comments** You can set the current pattern with [WinSetPattern](#).
- See Also** [WinDrawGrayLine](#), [WinDrawLine](#), [WinEraseLine](#),  
[WinInvertLine](#), [WinPaintLine](#), [WinPaintLines](#)

## WinFillRectangle

- Purpose** Draw a rectangle in the draw window with current pattern.
- Declared In** `Window.h`
- Prototype**  
`void WinFillRectangle (const RectangleType *rP,  
UInt16 cornerDiam)`
- Parameters**
- > `rP` Pointer to the rectangle to draw.
  - > `cornerDiam` Radius of rounded corners. Specify zero for square corners.
- Result** Returns nothing.

## Windows

### Window Functions

---

**Comments** You can set the current pattern with [WinSetPattern](#).  
The `cornerDiam` parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides.

**See Also** [WinDrawRectangle](#), [WinEraseRectangle](#),  
[WinInvertRectangle](#), [WinPaintRectangle](#)

## WinGetActiveWindow

**Purpose** Return the window handle of the active window.

**Declared In** `Window.h`

**Prototype** `WinHandle WinGetActiveWindow (void)`

**Parameters** None.

**Result** Returns the handle of the active window. All user input is directed to the active window.

**See Also** [WinSetActiveWindow](#), [WinGetDisplayWindow](#),  
[WinGetFirstWindow](#), [WinGetDrawWindow](#)

## WinGetBitmap

**Purpose** Return a pointer to a window's bitmap, which holds the window contents.

**Declared In** `Window.h`

**Prototype** `BitmapType *WinGetBitmap (WinHandle winHandle)`

**Parameters** `-> winHandle` Handle of window from which to get the bitmap.

**Result** Returns a pointer to the bitmap or `NULL` if `winHandle` is invalid.

**Comments** For onscreen windows, the bitmap returned always represents the whole screen. Thus, the top-left corner of the returned bitmap may not be the top-left corner of the window.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## WinGetBounds

**Purpose** Return the bounds of the current draw window in display-relative coordinates.

**Declared In** `Window.h`

**Prototype** `void WinGetBounds (WinHandle winH,  
RectangleType *rP)`

**Parameters**

-> winH	Handle to a window.
<- rP	Pointer to a rectangle.

**Result** Returns nothing.

**Comments** This function returns in `rP` the bounds of the window represented by `winH`. This corresponds to the convention used by [WinSetBounds](#), because it takes a window handle as an argument. Prior to Palm OS 4.0, `WinGetBounds` returned the bounds of the draw window, and did not take a window handle as an argument. If an application needed to determine the bounds of an arbitrary window, the application would call [WinSetDrawWindow](#) to temporarily set the draw window to the desired window, then `WinGetBounds` would be called to get the bounds of the draw window, then [WinSetDrawWindow](#) would be called again to restore the draw window. This is no longer necessary.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is **not** present. As of Palm OS 4.0, applications should use [WinGetDrawWindowBounds](#).

**See Also** [WinGetWindowExtent](#), [WinGetDrawWindowBounds](#)

## WinGetClip

- Purpose** Return the clipping rectangle of the draw window.
- Declared In** `Window.h`
- Prototype** `void WinGetClip (RectangleType *rP)`
- Parameters** `<- rP` Pointer to a structure to hold the clipping bounds.
- Result** Returns nothing.
- See Also** [WinSetClip](#)

---

## New WinGetCoordinateSystem

- Purpose** Get the coordinate system
- Declared In** `Window.h`
- Prototype** `UInt16 WinGetCoordinateSystem (void)`
- Parameters** None.
- Result** Returns a value representing the current coordinate system. See “[Window Coordinate System Constants](#)” on page 1163 for the values that this function can return.
- Comments** Use this function to determine the active coordinate system. Armed with this information, an application can properly initialize graphic primitive coordinates and dimensions, or can modify the coordinate system with [WinSetCoordinateSystem](#).
- Compatibility** Implemented only if the [High-Density Display Feature Set](#) is

present.

**See Also** [WinSetCoordinateSystem](#)

## WinGetDisplayExtent

**Purpose** Return the width and height of the display (the screen).

**Declared In** `Window.h`

**Prototype** `void WinGetDisplayExtent (Coord *extentX,  
Coord *extentY)`

**Parameters** `<- extentX` Pointer to the width of the display in pixels.  
`<- extentY` Pointer to the height of the display in pixels.

**Result** Returns nothing.

## WinGetDisplayWindow

**Purpose** Return the window handle of the display (screen) window.

**Declared In** `Window.h`

**Prototype** `WinHandle WinGetDisplayWindow (void)`

**Parameters** None.

**Result** Returns the handle of display window.

**Comments** The display window is created by the system at start-up; it has the same size as the Palm OS drawable area of the physical display (screen).

**See Also** [WinGetDisplayExtent](#), [WinGetActiveWindow](#),  
[WinGetDrawWindow](#)

## Windows

### Window Functions

---

## WinGetDrawWindow

- Purpose** Return the window handle of the current draw window.
- Declared In** `Window.h`
- Prototype** `WinHandle WinGetDrawWindow (void)`
- Parameters** None.
- Result** Returns handle of draw window.
- See Also** [WinGetDisplayWindow](#), [WinGetActiveWindow](#), [WinSetDrawWindow](#)

## WinGetDrawWindowBounds

- Purpose** Return the bounds of the draw window.
- Declared In** `Window.h`
- Prototype** `void WinGetDrawWindowBounds (RectangleType *rP)`
- Parameters** <- rP Pointer to the window bounds.
- Result** Returns nothing.
- Comments** A pointer to the bounds of the draw window is returned. This function is equivalent to [WinGetBounds](#) that was in Palm OS prior to 4.0.
- See Also** [WinGetBounds](#)

## WinGetFirstWindow

- Purpose** Return a pointer to the first window in the linked list of windows.
- Declared In** `Window.h`
- Prototype** `WinHandle WinGetFirstWindow (void)`
- Parameters** None.
- Result** Returns handle of first window.
- Comments** This function is usually used by the system only.
- See Also** [WinGetActiveWindow](#)

## WinGetFramesRectangle

- Purpose** Return the rectangle that includes a rectangle together with the specified frame around it.
- Declared In** `Window.h`
- Prototype** `void WinGetFramesRectangle (FrameType frame,  
const RectangleType *rP,  
RectangleType *obscuredRect)`
- Parameters**
- > `frame` Type of rectangle frame (see [FrameType](#)).
  - > `rP` Pointer to the rectangle to frame.
  - <- `obscuredRect` Pointer to the rectangle that includes both the specified rectangle and its frame.
- Result** Returns nothing.

## Windows

### Window Functions

---

**Comments** Frames are always drawn around (outside) a rectangle.

**See Also** [WinGetWindowFrameRect](#), [WinGetBounds](#)

## WinGetPattern

**Purpose** Return the current fill pattern.

**Declared In** `Window.h`

**Prototype** `void WinGetPattern (CustomPatternType *patternP)`

**Parameters** `<- patternP` Buffer where the current pattern is returned (see [CustomPatternType](#)).

**Result** Returns nothing.

**Comments** The fill pattern is used by [WinFillLine](#) and [WinFillRectangle](#). This function returns the value of `patternData` in the current drawing state. (See [DrawStateType](#).) The `patternData` field is only set if the `pattern` field is `customPattern`. Therefore, it's a good idea to use [WinGetPatternType](#) instead of this function on systems that support [WinGetPatternType](#).

**See Also** [WinSetPattern](#)

## WinGetPatternType

<b>Purpose</b>	Return the current pattern type.
<b>Declared In</b>	Window.h
<b>Prototype</b>	PatternType WinGetPatternType (void)
<b>Parameters</b>	None.
<b>Result</b>	Returns the current draw window pattern type (see <a href="#">PatternType</a> ). If the return value is customPattern, you can retrieve the pattern with <a href="#">WinGetPattern</a> .
<b>Comments</b>	The fill pattern is used by <a href="#">WinFillLine</a> and <a href="#">WinFillRectangle</a> .
<b>Compatibility</b>	Implemented only if <a href="#">3.5 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">WinSetPatternType</a>

## WinGetPixel

<b>Purpose</b>	Return the color value of a pixel in the current draw window.
<b>Declared In</b>	Window.h
<b>Prototype</b>	IndexedColorType WinGetPixel (Coord x, Coord y)
<b>Parameters</b>	-> x                    Pointer to the x coordinate of a pixel. -> y                    Pointer to the y coordinate of a pixel.
<b>Result</b>	Returns the indexed color value of the pixel. See <a href="#">IndexedColorType</a> . A return value of 0 means either that the coordinates do not lie in the current draw window or that they do and the color of that pixel is index 0 (typically white).

## Windows

### Window Functions

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinIndexToRGB](#)

## WinGetPixelRGB

**Purpose** Return the RGB color values of a pixel in the current draw window.

**Declared In** `Window.h`

**Prototype** `Err WinGetPixelRGB (Coord x, Coord y, RGBColorType *rgbP)`

**Parameters**

- > `x` Pointer to the x coordinate of a pixel.
- > `y` Pointer to the y coordinate of a pixel.
- <- `rgbP` RGB color components of the pixel.

**Result** Returns `errNone` or `sysErrParamErr`. `sysErrParamErr` is returned when the `x` or `y` arguments are < 0 or when they are outside the bounds of the draw window.

**Comments** The RGB color values of the pixel are returned as an [RGBColorType](#). This function can be used with both indexed or direct color modes. A return value of `sysErrParamErr` means that the coordinates do not lie in the current draw window.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

---

## **New** **WinGetSupportedDensity**

- Purpose** Enumerate the various display densities supported by the blitter.
- Declared In** `Window.h`
- Prototype** `Err WinGetSupportedDensity (UInt16 *densityP)`
- Parameters** `<-> densityP` Pointer to a supported density value. Set this value to zero before calling this function for the first time. Subsequent calls cause this value to be set to one of the display densities supported by the handheld.
- Result** Returns `errNone` unless the value you supply in `*densityP` isn't a supported density and isn't zero, in which case this function returns `SysErrParamErr`.
- Comments** Initialize `*densityP` to zero before your application calls this function for the first time. Repeated calls to `WinGetSupportedDensity` will cause the value pointed to by `densityP` to change; these values represent the supported display densities, in order from low to high density. After the last supported density value, this function sets `*densityP` back to zero.

---

**NOTE:** The densities reported by this function are those that are supported by the blitter. These densities are not necessarily supported by the underlying hardware. A handheld with a low-density screen that is able to scale high-density bitmaps will report that it can handle both high and low density bitmaps. Use [WinScreenGetAttribute](#) to determine the density of the handheld's screen.

---

Density values are defined in `Bitmap.h`; see the [DensityType](#) enum. Only those values supported by a given handheld will be returned by `WinGetSupportedDensity`. For example, on a

## Windows

### Window Functions

---

handheld with a double-density display this function returns `kDensityLow`, followed by `kDensityDouble`, followed by 0. For each supported density, the inverse scaling factor is supported. In this example, the blitter supports pixel-doubling low-density data for a double-density destination, and the blitter supports pixel-halving high-density data for a low-density destination.

The value pointed to by `densityP` should only be zero or one of the density values supported by the handheld. If it has any other value when you call `WinGetSupportedDensity`, this function will simply return `sysErrParamErr`.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

## WinGetWindowExtent

**Purpose** Return the width and height of the current draw window.

**Declared In** `Window.h`

**Prototype** `void WinGetWindowExtent (Coord *extentX,  
Coord *extentY)`

**Parameters**

<code>&lt;- extentX</code>	Pointer to the width in pixels of the draw window.
<code>&lt;- extentY</code>	Pointer to the height in pixels of the draw window.

**Result** Returns nothing.

**See Also** [WinGetBounds](#), [WinGetWindowFrameRect](#),

## WinGetWindowFrameRect

- Purpose** Return a rectangle, in display-relative coordinates, that defines the size and location of a window and its frame.
- Declared In** `Window.h`
- Prototype** `void WinGetWindowFrameRect (WinHandle winHandle, RectangleType *r)`
- Parameters**
- |                              |   |
|------------------------------|---|
| <code>-&gt; winHandle</code> | Handle of window whose coordinates are desired. |
| <code>&lt;- r</code>         | Pointer to the coordinates of the window.       |
- Result** Returns nothing.
- See Also** [WinGetBounds](#)

## WinIndexToRGB

- Purpose** Convert an index in the currently active color table to an RGB value.
- Declared In** `Window.h`
- Prototype** `void WinIndexToRGB (IndexedColorType i, RGBColorType *rgbP)`
- Parameters**
- |                         |  |
|-------------------------|--|
| <code>-&gt; i</code>    | A color index value. See <a href="#">IndexedColorType</a> .  |
| <code>&lt;- rgbP</code> | Pointer to an RGB color value corresponding to the index value <code>i</code> . See <a href="#">RGBColorType</a> . |
- Result** Returns nothing.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [WinRGBToIndex](#)

## WinInvertChars

- Purpose** Invert the specified characters in the draw window.
- Declared In** `Window.h`
- Prototype** `void WinInvertChars (const Char *chars, Int16 len, Coord x, Coord y)`
- Parameters**
- > `chars` Pointer to the characters to invert.
  - > `len` Length in bytes of the characters to invert.
  - > `x` x coordinate of the first character to invert (left bound).
  - > `y` y coordinate of the first character to invert (top bound).
- Result** Returns nothing.
- Comments** This function applies the `winInvert` operation of [WinDrawOperation](#) to the characters in the draw window. To perform color inverting, use [WinSetTextColor](#) and [WinSetBackColor](#) to choose the desired colors, and call [WinPaintChar](#).
- See Also** [WinDrawChar](#), [WinDrawChars](#), [WinDrawInvertedChars](#), [WinDrawTruncChars](#), [WinEraseChars](#), [WinPaintChar](#), [WinPaintChars](#)

## WinInvertLine

- Purpose** Invert a line in the draw window (using the [WinDrawOperation winInvert](#)).
- Declared In** Window.h
- Prototype** void WinInvertLine (Coord x1, Coord y1, Coord x2, Coord y2)
- Parameters**
- > x1 x coordinate of line start point.
  - > y1 y coordinate of line start point.
  - > x2 x coordinate of line endpoint.
  - > y2 y coordinate of line endpoint.
- Result** Returns nothing.
- See Also** [WinDrawGrayLine](#), [WinDrawLine](#), [WinEraseLine](#), [WinFillLine](#), [WinPaintLine](#), [WinPaintLines](#)

## WinInvertPixel

- Purpose** Invert a pixel in the draw window (using the [WinDrawOperation winInvert](#)).
- Declared In** Window.h
- Prototype** void WinInvertPixel (Coord x, Coord y)
- Parameters**
- > x Pointer to the x coordinate of a pixel.
  - > y Pointer to the y coordinate of a pixel.
- Result** Returns nothing.

## Windows

### Window Functions

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinDrawPixel](#), [WinErasePixel](#), [WinPaintPixel](#),  
[WinPaintPixels](#)

## WinInvertRectangle

**Purpose** Invert a rectangle in the draw window (using the [WinDrawOperation](#) winInvert).

**Declared In** Window.h

**Prototype** void WinInvertRectangle (const RectangleType \*rP,  
UInt16 cornerDiam)

**Parameters**

- > rP Pointer to the rectangle to invert.
- > cornerDiam Radius of rounded corners. Specify zero for square corners.

**Result** Returns nothing.

**Comments** The cornerDiam parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides.

The operating system itself does not use the inverting routines. Instead, it uses the winSwap transfer mode, or it changes the color selection and uses the WinPaint... routines.

**See Also** [WinDrawRectangle](#), [WinEraseRectangle](#),  
[WinFillRectangle](#), [WinPaintRectangle](#)

## WinInvertRectangleFrame

- Purpose** Invert a rectangular frame in the draw window (using the [WinDrawOperation](#) winInvert).
- Declared In** Window.h
- Prototype** void WinInvertRectangleFrame (FrameType frame, const RectangleType \*rP)
- Parameters**
- > frame           Type of frame to draw (see [FrameType](#)).
  - > rP                Pointer to the rectangle to frame.
- Result** Returns nothing.
- See Also** [WinDrawGrayRectangleFrame](#), [WinDrawRectangleFrame](#), [WinEraseRectangleFrame](#), [WinGetFramesRectangle](#), [WinPaintRectangleFrame](#)

## WinModal

- Purpose** Return true if the specified window is modal.
- Declared In** Window.h
- Prototype** Boolean WinModal (WinHandle winHandle)
- Parameters**
- > winHandle    Handle of a window.
- Result** Returns true if the window is modal, otherwise false.
- Comments** A window is modal if it cannot lose the focus.
- See Also** [FrmAlert](#), [FrmCustomAlert](#), [FrmDoDialog](#)

## WinPaintBitmap

**Purpose** Draw a bitmap in the current draw window at the specified coordinates with the current draw mode.

**Declared In** Window.h

**Prototype** void WinPaintBitmap (BitmapType \*bitmapP,  
Coord x, Coord y)

**Parameters**

- > bitmapP      Pointer to a bitmap.
- > x              The x coordinate of the top-left corner.
- > y              The y coordinate of the top-left corner.

**Result** Returns nothing.

**Comments** If the bitmap has multiple depths (is a bitmap family), the closest match less than or equal to the current draw window depth is used. If such a bitmap does not exist, the bitmap with the closest match greater than the draw window depth is used.

Using WinPaintBitmap is now recommended instead of the previous practice of rendering bitmaps into an offscreen window and then using [WinCopyRectangle](#) to draw them on screen.

The current draw mode is set by [WinSetDrawMode](#).

If the bitmap has its own color table, color conversion to the draw window color table will be applied (on OS 3.5 or later). This color conversion is slow and not recommended. Instead of including a color table in the bitmap, consider using [WinPalette](#) to change the system color table, draw the bitmap, and then change the system color table back when the bitmap is no longer visible.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinDrawBitmap](#), [WinEraseRectangle](#),  
[WinPaintTiledBitmap](#)

## WinPaintChar

<b>Purpose</b>	Draw a character in the draw window using the current drawing state.						
<b>Declared In</b>	Window.h						
<b>Prototype</b>	<code>void WinPaintChar (WChar theChar, Coord x, Coord y)</code>						
<b>Parameters</b>	<table><tr><td>-&gt; theChar</td><td>The character to draw. This may be either a single-byte character or a multi-byte character.</td></tr><tr><td>-&gt; x</td><td>x coordinate of the location where the character is to be drawn (left bound).</td></tr><tr><td>-&gt; y</td><td>y coordinate of the location where the character is to be drawn (top bound).</td></tr></table>	-> theChar	The character to draw. This may be either a single-byte character or a multi-byte character.	-> x	x coordinate of the location where the character is to be drawn (left bound).	-> y	y coordinate of the location where the character is to be drawn (top bound).
-> theChar	The character to draw. This may be either a single-byte character or a multi-byte character.						
-> x	x coordinate of the location where the character is to be drawn (left bound).						
-> y	y coordinate of the location where the character is to be drawn (top bound).						
<b>Result</b>	Returns nothing.						
<b>See Also</b>	<p>WinPaintChar draws the <b>on</b> bits in the text color and the <b>off</b> bits in the background color, with underlines (if any) drawn in the foreground color using the current drawing mode.</p> <p>This function uses the current drawing state, which is stored in a <a href="#">DrawStateType</a> structure. See the description of that structure to learn the functions you can call to set the drawing state to the values you want.</p>						
<b>Compatibility</b>	Implemented only if <a href="#">3.5 New Feature Set</a> is present.						
<b>See Also</b>	<a href="#">WinDrawChar</a> , <a href="#">WinDrawChars</a> , <a href="#">WinDrawInvertedChars</a> , <a href="#">WinDrawTruncChars</a> , <a href="#">WinEraseChars</a> , <a href="#">WinInvertChars</a> , <a href="#">WinPaintChars</a>						

## WinPaintChars

<b>Purpose</b>	Draw the specified characters in the draw window with the current draw state.								
<b>Declared In</b>	Window.h								
<b>Prototype</b>	<pre>void WinPaintChars (const Char *chars, Int16 len, Coord x, Coord y)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; chars</td><td>Pointer to the characters to draw.</td></tr><tr><td>-&gt; len</td><td>Length in bytes of the characters to draw.</td></tr><tr><td>-&gt; x</td><td>x coordinate of the first character to draw (left bound).</td></tr><tr><td>-&gt; y</td><td>y coordinate of the first character to draw (top bound).</td></tr></table>	-> chars	Pointer to the characters to draw.	-> len	Length in bytes of the characters to draw.	-> x	x coordinate of the first character to draw (left bound).	-> y	y coordinate of the first character to draw (top bound).
-> chars	Pointer to the characters to draw.								
-> len	Length in bytes of the characters to draw.								
-> x	x coordinate of the first character to draw (left bound).								
-> y	y coordinate of the first character to draw (top bound).								
<b>Result</b>	Returns nothing.								
<b>Comments</b>	<p>WinPaintChars draws the <b>on</b> bits in the text color and the <b>off</b> bits in the background color, with underlines (if any) drawn in the foreground color using the current drawing mode.</p> <p>This function uses the current drawing state, which is stored in a <a href="#">DrawStateType</a> structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.</p> <p>Before calling this function, consider calling <a href="#">WinSetUnderlineMode</a> and <a href="#">FntSetFont</a>.</p>								
<b>Compatibility</b>	Implemented only if <a href="#">3.5 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">WinDrawChar</a> , <a href="#">WinDrawChars</a> , <a href="#">WinDrawInvertedChars</a> , <a href="#">WinDrawTruncChars</a> , <a href="#">WinEraseChars</a> , <a href="#">WinInvertChars</a> , <a href="#">WinPaintChar</a>								

## WinPaintLine

<b>Purpose</b>	Draw a line in the draw window using the current drawing state.								
<b>Declared In</b>	Window.h								
<b>Prototype</b>	<pre>void WinPaintLine (Coord x1, Coord y1, Coord x2, Coord y2)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; x1</td><td>x coordinate of line beginning point.</td></tr><tr><td>-&gt; y1</td><td>y coordinate of line beginning point.</td></tr><tr><td>-&gt; x2</td><td>x coordinate of line endpoint.</td></tr><tr><td>-&gt; y2</td><td>y coordinate of line endpoint.</td></tr></table>	-> x1	x coordinate of line beginning point.	-> y1	y coordinate of line beginning point.	-> x2	x coordinate of line endpoint.	-> y2	y coordinate of line endpoint.
-> x1	x coordinate of line beginning point.								
-> y1	y coordinate of line beginning point.								
-> x2	x coordinate of line endpoint.								
-> y2	y coordinate of line endpoint.								
<b>Result</b>	Returns nothing.								
<b>Comments</b>	This function uses the current drawing state, which is stored in a <a href="#">DrawStateType</a> structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.								
<b>Compatibility</b>	Implemented only if <a href="#">3.5 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">WinDrawLine</a> , <a href="#">WinDrawGrayLine</a> , <a href="#">WinEraseLine</a> , <a href="#">WinFillLine</a> , <a href="#">WinInvertLine</a> , <a href="#">WinPaintLines</a>								

## WinPaintLines

<b>Purpose</b>	Draw several lines in the draw window using the current drawing state.		
<b>Declared In</b>	Window.h		
<b>Prototype</b>	<pre>void WinPaintLines (UInt16 numLines, WinLineType lines[])</pre>		
<b>Parameters</b>	<table><tr><td>-&gt; numLines</td><td>Number of lines to paint.</td></tr></table>	-> numLines	Number of lines to paint.
-> numLines	Number of lines to paint.		

## Windows

### Window Functions

---

-> lines            Array of lines. See [WinLineType](#).

**Result**        Returns nothing.

**Comments**     This function uses the current drawing state, which is stored in a [DrawStateType](#) structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

**See Also**        [WinDrawLine](#), [WinDrawGrayLine](#), [WinEraseLine](#),  
[WinFillLine](#), [WinInvertLine](#), [WinPaintLine](#)

## WinPaintPixel

**Purpose**         Render a pixel in the draw window using the current drawing state.

**Declared In**    Window.h

**Prototype**     void WinPaintPixel (Coord x, Coord y)

**Parameters**    -> x            Pointer to the x coordinate of a pixel.  
                 -> y            Pointer to the y coordinate of a pixel.

**Result**        Returns nothing.

**Comments**     This function uses the current drawing state, which is stored in a [DrawStateType](#) structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

**See Also**        [WinDrawPixel](#), [WinErasePixel](#), [WinInvertPixel](#),  
[WinPaintPixels](#)

## WinPaintPixels

<b>Purpose</b>	Render several pixels in the draw window using the current drawing state.
<b>Declared In</b>	Window.h
<b>Prototype</b>	<pre>void WinPaintPixels (UInt16 numPoints, PointType pts[])</pre>
<b>Parameters</b>	-> numPoints     Number of pixels to paint. -> pts            Array of pixels.
<b>Result</b>	Returns nothing.
<b>Comments</b>	This function uses the current drawing state, which is stored in a <a href="#">DrawStateType</a> structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.
<b>Compatibility</b>	Implemented only if <a href="#">3.5 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">WinDrawPixel</a> , <a href="#">WinErasePixel</a> , <a href="#">WinInvertPixel</a> , <a href="#">WinPaintPixel</a>

## WinPaintRectangle

<b>Purpose</b>	Draw a rectangle in the draw window using the current drawing state.
<b>Declared In</b>	Window.h
<b>Prototype</b>	<pre>void WinPaintRectangle (const RectangleType *rP, UInt16 cornerDiam)</pre>
<b>Parameters</b>	-> rP            Pointer to the rectangle to draw.

## Windows

### Window Functions

---

-> cornerDiam    Radius of rounded corners. Specify zero for square corners.

**Result**       Returns nothing.

**Comments**    The cornerDiam parameter specifies the radius of four imaginary circles used to form the rounded corners. An imaginary circle is placed within each corner tangent to the rectangle on two sides.

This function uses the current drawing state, which is stored in a [DrawStateType](#) structure. See the description of that structure to learn the functions you can call to set the drawing state to the state you want.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

**See Also**       [WinDrawRectangle](#), [WinEraseRectangle](#),  
[WinFillRectangle](#), [WinInvertRectangle](#)

## WinPaintRectangleFrame

**Purpose**       Draw a rectangular frame in the draw window using the current drawing state.

**Declared In**    Window.h

**Prototype**     void WinPaintRectangleFrame (FrameType frame,  
                                  const RectangleType \*rP)

**Parameters**    -> frame            Type of frame to draw (see [FrameType](#)).  
                  -> rP                Pointer to the rectangle to frame.

**Result**       Returns nothing.

**Comments**    The frame is drawn outside the specified rectangle.

This function uses the current drawing state, which is stored in a [DrawStateType](#) structure. See the description of that structure to

learn the functions you can call to set the drawing state to the state you want.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinDrawGrayRectangleFrame](#), [WinDrawRectangleFrame](#), [WinEraseRectangleFrame](#), [WinGetFramesRectangle](#), [WinInvertRectangleFrame](#), [WinPaintRoundedRectangleFrame](#)

---

## **New** **WinPaintRoundedRectangleFrame**

**Purpose** Draw a rectangular frame with rounded corners in the draw window using the current drawing state.

**Declared In** `Window.h`

**Prototype**

```
void WinPaintRoundedRectangleFrame
(const RectangleType *rP, Coord width,
Coord cornerRadius, Coord shadowWidth)
```

**Parameters**

- > `rP` Pointer to the rectangle to frame.
- > `width` The width of the frame, interpreted using the active coordinate system.
- > `cornerRadius` The radius of the rectangle's rounded corners, interpreted using the active coordinate system.
- > `shadowWidth` The shadow offset, interpreted using the active coordinate system.

**Result** Returns nothing.

**Comments** This function allows you to draw a rectangle with a frame width and corner radius specified in the active coordinate system. It is necessary because [WinPaintRectangleFrame](#) doesn't allow you to draw rounded rectangles with a frame width greater than 2. Note that because there isn't a function that parallels either

## Windows

### Window Functions

---

[WinDrawRectangleFrame](#), [WinEraseRectangleFrame](#), or [WinInvertRectangleFrame](#), you must set the drawing mode and colors as appropriate and use [WinPaintRoundedRectangleFrame](#) to achieve the desired effect.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

---

## New WinPaintTiledBitmap

**Purpose** Fill a rectangle with a pattern defined by a bitmap.

**Declared In** `Window.h`

**Prototype** `void WinPaintTiledBitmap (BitmapType *bitmapP, RectangleType *rectP)`

**Parameters**

-> <code>bitmapP</code>	Pointer to the bitmap that contains the desired pattern.
-> <code>rectP</code>	Pointer to the rectangle that is to be filled.

**Result** Returns nothing. On a debug ROM, if either `bitmapP` or `rectP` are `NULL`, an error is displayed.

**Comments** This function makes it possible for an application to define a pattern that is larger than the standard 8 by 8 custom pattern, and to define high-density custom patterns.

The pattern is scaled by the blitter using the density of `bitmapP` and the density of the screen bitmap. `bitmapP` can be a bitmap family; if it is, the Window Manager selects a bitmap using the same algorithm used by [WinPaintBitmap](#). As with other patterns, the tiled pattern is anchored to the window's origin.

If `bitmapP` does not match the depth or density of the destination bitmap, the blitter converts the bitmap using a temporary buffer.

Note that if there isn't enough heap space for the temporary buffer, `WinPaintTiledBitmap` will be slow.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

## WinPalette

**Purpose** Set or retrieve the palette for the draw window.

**Declared In** `Window.h`

**Prototype** `Err WinPalette (UInt8 operation, Int16 startIndex, UInt16 paletteEntries, RGBColorType *tableP)`

**Parameters** `-> operation` Specify one of the following values:

- `winPaletteGet`  
Retrieve the palette. Entries are read from the palette beginning at `startIndex` and placed into `tableP` beginning at index 0.
- `winPaletteSet`  
Set the palette. Entries from `tableP` (beginning at index 0) are set into the palette beginning at `startIndex` in the palette.
- `winPaletteSetToDefault`  
Set the palette to the default system palette.

## Windows

### Window Functions

---

- > `startIndex` Identifies where in the palette to start reading or writing. Specify `WinUseTableIndexes` to indicate that the entries are not to be set or read sequentially; instead, the `index` value in each `RGBColorType` entry in `tableP` determines which slot in the palette is to be set or read. You can use this technique to get or set several discontinuous palette entries with a single function call.
- > `paletteEntries` Number of palette entries to get or set.
- <-> `tableP` A pointer to a buffer of `RGBColorType` entries that is either read from or written to, depending on the operation parameter; the table entries from 0 to `paletteEntries - 1` are affected by this routine.

**Result** Returns one of the following values:

- `errNone` Success.
- `winErrPalette` The current draw window does not have a color table, a set operation has overflowed the color table, or one of the entries in `tableP` has an invalid index value
- `sysErrParamErr` The `startIndex` value is invalid.

**Comments** Here are some examples of how this routine works:

- If `startIndex` is 0 and `paletteEntries` is 10, the first 10 elements of the palette will be set from `tableP` or will be copied into `tableP`.
- If `startIndex` is 10 and `paletteEntries` is 5, then entries 10, 11, 12, 13, and 14 in the palette will be set from or copied to elements 0, 1, 2, 3, and 4 in `tableP`.
- If `startIndex` is `WinUseTableIndexes` and `paletteEntries` is 1, then the index value in the `RGBColorType` of element 0 of `tableP` will be read from or copied to `tableP`; in this case, the index field of the `RGBColorType` will not change.

During a set operation, this function broadcasts the [sysNotifyDisplayChangeEvent](#) to notify any interested observer that the color palette has changed.

One use for this function is if you need to display a bitmap that uses a color table other than the one in use by the system. You can attach a custom color table to a bitmap, and if you do, the bitmap is drawn using that color table. However, this is a performance drain. As an optimization, you can use `WinPalette` to change the system color table to match that used by the bitmap, display the bitmap, and use `WinPalette` to reset the color table when the bitmap is no longer visible.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## WinPopDrawState

**Purpose** Restore the draw state values to the last saved set on the stack.

**Declared In** `Window.h`

**Prototype** `void WinPopDrawState (void)`

**Parameters** None.

**Result** Returns nothing.

**Comments** Use this routine to restore the draw state saved by the previous call to [WinPushDrawState](#).

After you call this function, the current draw window's `drawStateP` field points to the restored drawing state.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## WinPushDrawState

- Purpose** Save the current draw state values onto the draw state stack.
- Declared In** `Window.h`
- Prototype** `void WinPushDrawState (void)`
- Parameters** None.
- Result** Returns nothing.
- Comments** Use this routine to save the current draw state before making changes to it using the functions listed in the [DrawStateType](#) structure's description. Call [WinPopDrawState](#) to restore the saved settings.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## WinResetClip

- Purpose** Reset the clipping rectangle of the draw window to the portion of the draw window that is within the bounds of the display.
- Declared In** `Window.h`
- Prototype** `void WinResetClip (void)`
- Parameters** None.
- Result** Returns nothing.
- See Also** [WinSetClip](#)

## WinRestoreBits

<b>Purpose</b>	Copy the contents of the specified window to the draw window and delete the passed window.						
<b>Declared In</b>	Window.h						
<b>Prototype</b>	<pre>void WinRestoreBits (WinHandle winHandle, Coord destX, Coord destY)</pre>						
<b>Parameters</b>	<table><tr><td>-&gt; winHandle</td><td>Handle of window to copy and delete.</td></tr><tr><td>-&gt; destX</td><td>x coordinate in the draw window to copy to.</td></tr><tr><td>-&gt; destY</td><td>y coordinate in the draw window to copy to.</td></tr></table>	-> winHandle	Handle of window to copy and delete.	-> destX	x coordinate in the draw window to copy to.	-> destY	y coordinate in the draw window to copy to.
-> winHandle	Handle of window to copy and delete.						
-> destX	x coordinate in the draw window to copy to.						
-> destY	y coordinate in the draw window to copy to.						
<b>Result</b>	Returns nothing.						
<b>Comments</b>	This routine is generally used to restore a region of the display that was saved with <a href="#">WinSaveBits</a> .						
<b>See Also</b>	<a href="#">WinSaveBits</a>						

## WinRGBToIndex

<b>Purpose</b>	Convert an RGB value to the index of the closest color in the currently active color lookup table (CLUT).		
<b>Declared In</b>	Window.h		
<b>Prototype</b>	<pre>IndexedColorType WinRGBToIndex (const RGBColorType *rgbP)</pre>		
<b>Parameters</b>	<table><tr><td>-&gt; rgbP</td><td>Pointer to an RGB color value.</td></tr></table>	-> rgbP	Pointer to an RGB color value.
-> rgbP	Pointer to an RGB color value.		
<b>Result</b>	Returns the index of the closest matching color in the CLUT.		
<b>Comments</b>	Palm OS 3.5 supports a maximum of 256 colors. The number of possible RGB colors greatly exceeds this amount. For this reason, an		

## Windows

### Window Functions

---

exact match may not be available for `rgbP`. If there is no exact RGB match, then a luminance best-fit is used if the color lookup table is entirely gray scale (red, green, and blue values for each entry are identical), or a shortest-distance fit in RGB space is used if the palette contains colors. RGB shortest distance may not always produce the actual closest perceptible color, but it's relatively fast and works for the system palette.

`WinRGBToIndex` uses the draw window's color table to return the appropriate color table index. If the draw window does not have a color table, the default color table of the current screen is used.

If the draw window does not have a color table, and if the depth of the draw window and the depth of the screen are different, this function will return an inappropriate index. If this situation exists, the application should either define a color table for the draw window, or use [WinScreenMode](#) to set the screen depth to the same depth as the draw window before calling `WinRGBToIndex`.

---

**NOTE:** The bitmap data will not be blitted properly if the depth of the screen is changed using [WinScreenMode](#) and the new window uses a bitmap that does not define the bitmap's color table. See [WinScreenMode](#) for information on how to work around this limitation.

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinIndexToRGB](#), [WinScreenMode](#)

## WinSaveBits

- Purpose** Create an offscreen window and copy the specified region from the draw window to the offscreen window.
- Declared In** `Window.h`
- Prototype** `WinHandle WinSaveBits  
(const RectangleType *source, UInt16 *error)`
- Parameters**
- |                           |   |
|---------------------------|---|
| <code>-&gt; source</code> | Pointer to the bounds of the region to save, relative to the display. |
| <code>&lt;- error</code>  | Pointer to any error encountered by this function.                    |
- Result** Returns the handle of the window containing the saved image, or zero if an error occurred.
- Comments** The offscreen window is the same size as the region to copy.  
This function tries to copy the window's bitmap using compressed format if possible. It may display a fatal error message if an error occurs when it tries to shrink the pointer for the compressed bits.
- See Also** [WinRestoreBits](#)

## New WinScaleCoord

---

<b>Purpose</b>	Convert a single coordinate from the standard coordinate system to the active coordinate system.				
<b>Declared In</b>	Window.h				
<b>Prototype</b>	<code>Coord WinScaleCoord (Coord coord, Boolean ceiling)</code>				
<b>Parameters</b>	<table><tr><td>-&gt; <code>coord</code></td><td>A coordinate in the standard coordinate system.</td></tr><tr><td>-&gt; <code>ceiling</code></td><td>Pass true to round up, false to truncate the fractional part when scaling.</td></tr></table>	-> <code>coord</code>	A coordinate in the standard coordinate system.	-> <code>ceiling</code>	Pass true to round up, false to truncate the fractional part when scaling.
-> <code>coord</code>	A coordinate in the standard coordinate system.				
-> <code>ceiling</code>	Pass true to round up, false to truncate the fractional part when scaling.				
<b>Result</b>	Returns the coordinate scaled to the active coordinate system.				
<b>Comments</b>	<p>This function converts a coordinate by multiplying it by the coordinate scaling factor, and then truncating or rounding the result to an integer value depending on the value of <code>ceiling</code>.</p> <p>If the active coordinate system is <code>kCoordinatesStandard</code>, the returned coordinate is equal to the supplied coordinate.</p>				
<b>Compatibility</b>	Implemented only if the <a href="#">High-Density Display Feature Set</a> is present.				
<b>See Also</b>	<a href="#">WinScalePoint</a> , <a href="#">WinScaleRectangle</a> , <a href="#">WinUnscaleCoord</a>				

---

## **New** **WinScalePoint**

<b>Purpose</b>	Convert a point from the standard coordinate system to the active coordinate system.				
<b>Declared In</b>	Window.h				
<b>Prototype</b>	<code>void WinScalePoint (PointType *pointP, Boolean ceiling)</code>				
<b>Parameters</b>	<table><tr><td><code>&lt;-&gt; pointP</code></td><td>Pointer to a <code>PointType</code> structure that, before the call, should contain a point's standard coordinate system coordinates. After this function is called the <code>PointType</code> structure contains the coordinates of the point scaled to the active coordinate system.</td></tr><tr><td><code>-&gt; ceiling</code></td><td>Pass <code>true</code> to round up, <code>false</code> to truncate the fractional part when scaling.</td></tr></table>	<code>&lt;-&gt; pointP</code>	Pointer to a <code>PointType</code> structure that, before the call, should contain a point's standard coordinate system coordinates. After this function is called the <code>PointType</code> structure contains the coordinates of the point scaled to the active coordinate system.	<code>-&gt; ceiling</code>	Pass <code>true</code> to round up, <code>false</code> to truncate the fractional part when scaling.
<code>&lt;-&gt; pointP</code>	Pointer to a <code>PointType</code> structure that, before the call, should contain a point's standard coordinate system coordinates. After this function is called the <code>PointType</code> structure contains the coordinates of the point scaled to the active coordinate system.				
<code>-&gt; ceiling</code>	Pass <code>true</code> to round up, <code>false</code> to truncate the fractional part when scaling.				
<b>Result</b>	Returns nothing. The coordinates of the point indicated by <code>pointP</code> are converted to the active coordinate system.				
<b>Comments</b>	This function converts a point by multiplying its x and y coordinates by the coordinate scaling factor and then truncating or rounding the the results depending on the value of <code>ceiling</code> .  If the active coordinate system is <code>kCoordinatesStandard</code> , <code>pointP</code> is not changed by this function.				
<b>Compatibility</b>	Implemented only if the <a href="#">High-Density Display Feature Set</a> is present.				
<b>See Also</b>	<a href="#">WinScaleCoord</a> , <a href="#">WinScaleRectangle</a> , <a href="#">WinUnscalePoint</a>				

---

**New WinScaleRectangle**

**Purpose** Convert a rectangle from the standard coordinate system to the active coordinate system.

**Declared In** `Window.h`

**Prototype** `void WinScaleRectangle (RectangleType *rectP)`

**Parameters** `<-> rectP` Pointer to a `RectangleType` structure that, before the call, should contain a rectangle's standard coordinate system coordinates. After this function is called the `RectangleType` structure contains the coordinates of the rectangle scaled to the active coordinate system.

**Result** Returns nothing. The coordinates of the rectangle indicated by `rectP` are converted to the native coordinate system.

**Comments** This function scales the rectangle's `topLeft` and `extent` points by multiplying their `x` and `y` coordinates by the coordinate scaling factor. All values are then truncated, but if either `topLeft.x` or `extent.x` had a fractional part, `extent.x` is incremented by 1 (and, similarly, if either `topLeft.y` or `extent.y` had a fractional part, `extent.y` is incremented by 1).

If the active coordinate system is `kCoordinatesStandard`, `rectP` is not changed by this function.

You can use this function when your gadget handler draws using a more precise coordinate system than the Form Manager and needs to convert the form-based bounds of the gadget to the high-density bounds used by the gadget's drawing function.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is

present.

**See Also** [WinScaleCoord](#), [WinScalePoint](#), [WinUnscaleRectangle](#)

---

## **New** **WinScreenGetAttribute**

**Purpose** Get various attributes of the screen.

**Declared In** `Window.h`

**Prototype** `Err WinScreenGetAttribute  
(WinScreenAttrType selector, UInt32 *attrP)`

**Parameters**

<code>-&gt; selector</code>	A value indicating which attribute to return. See the description of <a href="#">WinScreenAttrType</a> in the Comments section, below, for the values you can supply to this parameter.
<code>&lt;- attrP</code>	Pointer to a <code>UInt32</code> into which the specified attribute value is placed by this function.

**Result** Returns `errNone` if the function successfully retrieved the specified attribute, or `sysErrParamErr` if `selector` doesn't represent a screen attribute.

**Comments** This function returns many of the attributes that can be obtained with [WinScreenMode](#). Unlike `WinScreenMode`, however, this function can also return the number of bytes used by each row in the screen buffer as well as the number of pixels per inch on the screen's x and y axes.

Unlike `WinScreenMode`, you cannot set any attributes with this function. Also, you cannot use this function to obtain the "color enabled" attribute. And unlike `WinScreenMode`, this function always returns the true screen dimensions; `WinScreenMode` converts the dimensions to the active coordinate system.

## Windows

### Window Functions

---

Applications can use the screen resolution information to make intelligent decisions about how to draw primitives on Palm Powered handhelds with different screen resolutions.

#### WinScreenAttrType

This enum defines the selectors that can be used with the [WinScreenGetAttribute](#) function.

```
typedef enum {
    winScreenWidth,
    winScreenHeight,
    winScreenRowBytes,
    winScreenDepth,
    winScreenAllDepths,
    winScreenDensity,
    winScreenPixelFormat,
    winScreenResolutionX,
    winScreenResolutionY
} WinScreenAttrType;
```

#### Value Descriptions

<code>winScreenWidth</code>	The width of the screen, in pixels.
<code>winScreenHeight</code>	The height of the screen, in pixels.
<code>winScreenRowBytes</code>	The number of bytes used by each row in the screen buffer.
<code>winScreenDepth</code>	The screen depth.
<code>winScreenAllDepths</code>	All screen depths (in bitmap format).
<code>winScreenDensity</code>	The screen bitmap's density.
<code>winScreenPixelFormat</code>	The <a href="#">PixelFormatType</a> appropriate for the screen.
<code>winScreenResolutionX</code>	The number of pixels per inch along the screen's x axis.
<code>winScreenResolutionY</code>	The number of pixels per inch along the screen's y axis.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is

present.

**See Also** [WinScreenMode](#)

## WinScreenLock

**Purpose** “Lock” the current screen by switching the UI concept of the screen base address to an area that is not reflected on the display.

**Declared In** `Window.h`

**Prototype** `UInt8 *WinScreenLock (WinLockInitType initMode)`

**Parameters** `-> initMode` Indicates how to initialize the new screen area. Specify one of the following values:

- `winLockCopy`  
Copy old screen to new.
- `winLockErase`  
Erase new screen to white.
- `winLockDontCare`  
Don't do anything

**Result** Returns a pointer to the new screen base address, or NULL if this routine fails.

**Comments** This routine can be used to “freeze” the display while doing lengthy drawing operations to avoid a flickering effect. Call [WinScreenUnlock](#) to unlock the display and cause it to be updated with any changes. The screen must be unlocked as many times as it is locked to actually update the display.

Because this function copies the screen, using it is a relatively expensive operation.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## WinScreenMode

- Purpose** Sets or returns display parameters, including display geometry, bit depth, and color support.
- Declared In** `Window.h`
- Prototype** `Err WinScreenMode  
(WinScreenModeOperation operation,  
UInt32 *widthP, UInt32 *heightP, UInt32 *depthP,  
Boolean *enableColorP)`
- Parameters** The `widthP`, `heightP`, `depthP`, and `enableColorP` parameters are used in different ways for different operations. See [Comments](#) at the end of this description for details.
- > `operation` The work this function is to perform, as specified by one of the following selectors:
- `winScreenModeGet`  
Return the current settings for the display.
  - `winScreenModeGetDefaults`  
Return the default settings for the display.
  - `winScreenModeGetSupportedDepths`  
Return in `depthP` a hexadecimal value indicating the supported screen depths. The binary representation of this value defines a bitfield in which the value 1 indicates support for a particular display depth. The position representing a particular bit depth corresponds to the value  $2^{(\text{bitDepth}-1)}$ . See the [Example](#) at the end of this function description for more information.

`winScreenModeGetSupportsColor`

Return `true` as the value of the `enableColorP` parameter when color mode can be enabled.

`winScreenModeSet`

Change display settings to the values specified by the other arguments to the `WinScreenMode` function.

`winScreenModeSetToDefaults`

Change display settings to default values.

`<-> widthP`

Pointer to new/old screen width. For backward compatibility, when operation is `winScreenModeGet` or `winScreenModeGetDefaults`, a single-density width is returned, even if the handheld has a double-density display. Use [WinScreenGetAttribute](#) to retrieve the true hardware dimensions of the display.

`<-> heightP`

Pointer to new/old screen height. . For backward compatibility, when operation is `winScreenModeGet` or `winScreenModeGetDefaults`, a single-density height is returned, even if the handheld has a double-density display. Use [WinScreenGetAttribute](#) to retrieve the true hardware dimensions of the display.

`<-> depthP`

Pointer to new/old/available screen depth.

## Windows

### Window Functions

---

<-> enableColorP

Pass `true` to enable color drawing mode. The returned value (when using an operation that returns a value through this parameter) simply indicates whether or not the hardware supports color; its value does not change based on the current screen depth.

**Result** If no error, returns values as specified by the `operation` argument. Various invalid arguments may cause this function to return a `sysErrParamErr` result code. In rare cases, a failed allocation can cause this function to return a `memErrNotEnoughSpace` error.

**Comments** The `widthP`, `heightP`, `depthP`, and `enableColorP` parameters are used in different ways for different operations. All “get” operations overwrite these values with a result when the function returns. The `winScreenModeSet` operation changes current display parameters when passed valid argument values that are not `NULL` pointers. The `winScreenModeSetToDefaults` operation ignores values passed for all of these parameters.

[Table 54.1](#) summarizes parameter usage for each operation this function performs.

**Table 54.1 Use of parameters to WinScreenMode function**

<b>Operation</b>	<b>winScreenMode...</b>	<b>widthP</b>	<b>heightP</b>	<b>depthP</b>	<b>enableColorP</b>
...Get		returned	returned	returned	returned
...GetDefaults		returned	returned	returned	returned
...GetSupportedDepths		ignored	ignored	returned	pass in
...GetSupportsColor		ignored	ignored	pass in	returned
...Set		pass in	pass in	pass in	pass in
...SetToDefaults		ignored	ignored	ignored	ignored

This function ignores NULL pointer arguments to the `widthP`, `heightP`, `depthP`, and `enableColorP` parameters; thus, you can pass a NULL pointer for any of these values to leave the current value unchanged. Similarly, when getting values, this function does not return a value for any NULL pointer argument.

If you change the display depth, it is recommended that you restore it to its previous state when your application closes, even though the system sets display parameters back to their default values when launching an application.

Note that none of the other operations interprets the `depth` parameter the same way that `winScreenModeGetSupportedDepths` does. For example, to set the display depth to 8-bit mode, you use 8 (decimal) for the display depth, not 0x80 (128 decimal).

When a window is created, and if the window's associated bitmap does not have its own color table, the window will use the system's default color translation tables when a blitting operation occurs to that window. When the system's bit depth changes, the system's default color translation tables are recalculated based on the new screen depth. When the blit occurs at the new screen depth to the offscreen window, the color translation tables are out of sync.

To workaroud this system limitation, developers should either:

- allocate offscreen windows after changing the depth, or

## Windows

### Window Functions

---

- use [WinCreateBitmapWindow](#) so that it uses a bitmap with a defined color table.

The latter workaround causes the system to perform color matching when blitting, so the first workaround may be preferred.

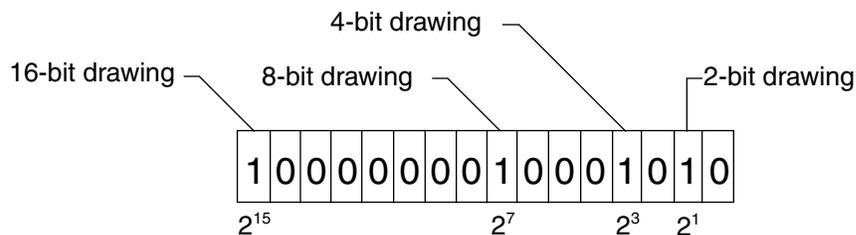

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. In OS versions prior to 3.5, this function is called `ScrDisplayMode`. The prototype for `ScrDisplayMode` is similar to `WinScreenMode`:

```
Err ScrDisplayMode (  
    ScrDisplayModeOperation operation,  
    DWordPtr widthP, DWordPtr heightP,  
    DWordPtr depthP, BooleanPtr enableColorP)
```

The only other difference between `ScrDisplayMode` and `WinScreenMode` is that the `ScrDisplayModeOperation` constants begin with the prefix `scrDisplayMode` rather than `winScreenMode`.

**Example** Here are some additional examples of return values provided by the `winScreenModeGetSupportedDepths` mode of the `WinScreenMode` function.

This function indicates support for 4-bit drawing by returning a value of `0x08`, or  $2^3$ , which corresponds to a binary value of `1000`. Support for bit depths of 2 and 1 is indicated by a return value of `0x03`. Support for bit depths of 4, 2, and 1 is indicated by `0x0B`, which is a binary value of `1011`. Support for bit depths of 16, 8, 4 and 2 is indicated by `0x808A`. The figure immediately following depicts this final example graphically.

**See Also** [WinScreenGetAttribute](#)

## WinScreenUnlock

<b>Purpose</b>	Unlock the screen and update the display.
<b>Declared In</b>	Window.h
<b>Prototype</b>	<code>void WinScreenUnlock (void)</code>
<b>Parameters</b>	None.
<b>Result</b>	Returns nothing.
<b>Comments</b>	The screen must be unlocked as many times as it is locked to actually update the display.
<b>Compatibility</b>	Implemented only if <a href="#">3.5 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">WinScreenLock</a>

## WinScrollRectangle

<b>Purpose</b>	Scroll a rectangle in the draw window.						
<b>Declared In</b>	Window.h						
<b>Prototype</b>	<code>void WinScrollRectangle (const RectangleType *rP, WinDirectionType direction, Coord distance, RectangleType *vacatedP)</code>						
<b>Parameters</b>	<table><tr><td>-&gt; rP</td><td>Pointer to the rectangle to scroll.</td></tr><tr><td>-&gt; direction</td><td>Direction to scroll (winUp, winDown, winLeft, or winRight).</td></tr><tr><td>-&gt; distance</td><td>Distance to scroll in pixels.</td></tr></table>	-> rP	Pointer to the rectangle to scroll.	-> direction	Direction to scroll (winUp, winDown, winLeft, or winRight).	-> distance	Distance to scroll in pixels.
-> rP	Pointer to the rectangle to scroll.						
-> direction	Direction to scroll (winUp, winDown, winLeft, or winRight).						
-> distance	Distance to scroll in pixels.						

## Windows

### Window Functions

---

`<- vacatedP`      Pointer to the rectangle that needs to be redrawn because it has been vacated as a result of the scroll.

**Result**      Returns nothing.

**Comments**      The rectangle scrolls within its own bounds. Any portion of the rectangle that is scrolled outside its bounds is clipped.

## WinSetActiveWindow

**Purpose**      Make a window the active window.

**Declared In**      `Window.h`

**Prototype**      `void WinSetActiveWindow (WinHandle winHandle)`

**Parameters**      `-> winHandle`      Handle of a window.

**Result**      Returns nothing.

**Comments**      The active window is not actually set in this routine; flags are set to indicate that a window is being exited and another window is being entered. The routine `EvtGetEvent` sends a [winExitEvent](#) and a [winEnterEvent](#) when it detects these flags. The active window is set by `EvtGetEvent` when it sends the `winEnterEvent`. The draw window is also set to the new active window when the active window is changed.

The window is enabled before it is made active.

All user input is directed to the active window.

**See Also**      [WinGetActiveWindow](#), [EvtGetEvent](#)

## WinSetBackColor

- Purpose** Set the background color to use in subsequent draw operations.
- Declared In** `Window.h`
- Prototype** `IndexedColorType WinSetBackColor  
(IndexedColorType backColor)`
- Parameters** `-> backColor` Color to set; specify a value of type [IndexedColorType](#).
- Result** Returns the previous background color index.
- Comments** This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later. To set the foreground color to a predefined UI color default, use [UIColorGetTableEntryIndex](#) as an input to this function. For example:
- ```
curColor = WinSetBackColor  
(UIColorGetTableEntryIndex(UIFieldBackground));
```
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [WinSetForeColor](#), [WinSetTextColor](#)

## WinSetBackColorRGB

- Purpose** Set the background color to use in subsequent draw operations.
- Declared In** `Window.h`
- Prototype**  
`void WinSetBackColorRGB  
(const RGBColorType *newRgbP,  
RGBColorType *prevRgbP)`
- Parameters**
- |             |                                                                        |
|-------------|------------------------------------------------------------------------|
| -> newRgbP  | Color to set; specify a value of type <a href="#">RGBColorType</a> .   |
| <- prevRgbP | Previous color; specify a value of type <a href="#">RGBColorType</a> . |
- Result** Returns nothing
- Comments** This function takes new and previous [RGBColorType](#) arguments. It is okay to set newRgbP or prevRgbP to NULL. If an application only wants to get the current color, the newRgbP argument is set to NULL. If the application does not care about the previous color, prevRgbP can be set to NULL.
- This function sets the backColorRGB field of the [DrawStateType](#) structure to the value specified by newRgbP. It then sets the index field of backColorRGB to the 8 bit system palette entry that most closely matches the RGB components. Finally, it sets the backColor index field of [DrawStateType](#) to this index value.
- This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [WinSetForeColorRGB](#), [WinSetTextColorRGB](#)

## WinSetBounds

|                      |                                                                                                                                                                                         |              |                                                    |       |                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------------------------------------------------|-------|-------------------------------------------|
| <b>Purpose</b>       | Set the bounds of the window to display-relative coordinates.                                                                                                                           |              |                                                    |       |                                           |
| <b>Declared In</b>   | Window.h                                                                                                                                                                                |              |                                                    |       |                                           |
| <b>Prototype</b>     | <pre>void WinSetBounds (WinHandle winHandle,<br/>const RectangleType *rP)</pre>                                                                                                         |              |                                                    |       |                                           |
| <b>Parameters</b>    | <table><tr><td>-&gt; winHandle</td><td>Handle for the window for which to set the bounds.</td></tr><tr><td>-&gt; rP</td><td>Pointer to a rectangle to use for bounds.</td></tr></table> | -> winHandle | Handle for the window for which to set the bounds. | -> rP | Pointer to a rectangle to use for bounds. |
| -> winHandle         | Handle for the window for which to set the bounds.                                                                                                                                      |              |                                                    |       |                                           |
| -> rP                | Pointer to a rectangle to use for bounds.                                                                                                                                               |              |                                                    |       |                                           |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                        |              |                                                    |       |                                           |
| <b>Comments</b>      | A visible window cannot have its bounds modified.                                                                                                                                       |              |                                                    |       |                                           |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                     |              |                                                    |       |                                           |

## New WinSetCoordinateSystem

|                    |                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Establish the coordinate system to be used for subsequent drawing operations.                                                                            |
| <b>Declared In</b> | Window.h                                                                                                                                                 |
| <b>Prototype</b>   | <pre>UInt16 WinSetCoordinateSystem (UInt16 coordSys)</pre>                                                                                               |
| <b>Parameters</b>  | -> coordSys      The desired coordinate system. Supply one of the values defined in “ <a href="#">Window Coordinate System Constants</a> ” on page 1163. |
| <b>Result</b>      | Returns the previous coordinate system value.                                                                                                            |

**Comments** This function modifies the `scale` field in the draw state (a [DrawStateType](#) structure). As when making other modifications to a window's draw state, applications should call [WinPushDrawState](#) before modifying the coordinate system. To restore the coordinate system, your application can then call [WinPopDrawState](#).

To calculate the draw state `scale` field, the Window Manager divides the density of the bitmap associated with the draw window by `coordSys`. If `coordSys` is `kCoordinatesNative`, the Window Manager sets the `scale` field to 1.0, which enables 1-to-1 mapping of coordinates to pixels.

If you supply a value of `kCoordinatesStandard` for `coordSys`, subsequent drawing will use the standard coordinate system.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [WinGetCoordinateSystem](#)

## WinSetDrawWindow

**Purpose** Set the draw window. (All drawing operations are relative to the draw window.)

**Declared In** `Window.h`

**Prototype** `WinHandle WinSetDrawWindow (WinHandle winHandle)`

**Parameters** `-> winHandle` Handle of a window.

**Result** Returns the previous draw window.

**Compatibility** OS versions before 3.5 allowed you to use `NULL` as a parameter to this function to set the draw window to the display window (or screen window). In version 3.5 and higher, this practice is discouraged. If `winHandle` is `NULL`, the debug ROM sets the draw

## Windows

### Window Functions

---

window to `badDrawWindowValue`, and you are warned if you try to draw to it.

**See Also** [WinGetDrawWindow](#), [WinSetActiveWindow](#)

## WinSetForeColor

**Purpose** Set the foreground color to use in subsequent draw operations.

**Declared In** `Window.h`

**Prototype** `IndexedColorType WinSetForeColor  
(IndexedColorType foreColor)`

**Parameters** `-> foreColor` Color to set; specify a value of type [IndexedColorType](#).

**Result** Returns the previous foreground color index.

**Comments** This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later.

To set the foreground color to a predefined UI color default, use [UIColorGetTableEntryIndex](#) as an input to this function. For example:

```
curColor = WinSetForeColor  
    (UIColorGetTableEntryIndex  
    (UIObjectForeground)) ;
```

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinSetBackColor](#), [WinSetTextColor](#)

## WinSetForeColorRGB

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                                                      |             |                                                                        |

| <b>Comments</b>      | <p>This function takes new and previous <a href="#">RGBColorType</a> arguments. It is okay to set newRgbP or prevRgbP to NULL. If an application only wants to get the current color, the newRgbP argument is set to NULL. If the application does not care about the previous color, prevRgbP can be set to NULL.</p> <p>This function sets the foreColorRGB field of the <a href="#">DrawStateType</a> structure to the value specified by newRgbP. It then sets the index field of foreColorRGB to the 8 bit system palette entry that most closely matches the RGB components. Finally, it sets the foreColor index field of <a href="#">DrawStateType</a> to this index value.</p> <p>This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState</a> to restore it later.</p> |            |                                                                      |             |                                                                        |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |            |                                                                      |             |                                                                        |
| <b>See Also</b>      | <a href="#">WinSetBackColorRGB</a> , <a href="#">WinSetTextColorRGB</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |            |                                                                      |             |                                                                        |

## WinSetPattern

- Purpose** Set the current fill pattern.
- Declared In** `Window.h`
- Prototype**  
`void WinSetPattern  
(const CustomPatternType *patternP)`
- Parameters** `-> patternP` Pattern to set (see [CustomPatternType](#)).
- Result** Returns nothing.
- Comments** The fill pattern is used by [WinFillLine](#) and [WinFillRectangle](#). This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later.
- See Also** [WinGetPattern](#)

## WinSetPatternType

- Purpose** Set the current pattern type.
- Declared In** `Window.h`
- Prototype**  
`void WinSetPatternType (PatternType newPattern)`
- Parameters** `-> newPattern` Pattern type to set for the draw window (see [PatternType](#)).
- Result** Returns nothing.
- Comments** This function sets the pattern field of the drawing state to `newPattern` and sets the `patternData` field to `NULL`. To set `patternData` to a custom pattern use [WinSetPattern](#).  
The fill pattern is used by [WinFillLine](#) and [WinFillRectangle](#).

This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinGetPatternType](#)

## WinSetTextColor

**Purpose** Set the color to use for drawing characters in subsequent draw operations.

**Declared In** `Window.h`

**Prototype** `IndexedColorType WinSetTextColor  
(IndexedColorType textColor)`

**Parameters** `-> textColor` Color to set; specify a value of type [IndexedColorType](#).

**Result** Returns the previous text color index.

**Comments** This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later.

To set the foreground color to a predefined UI color default, use [UIColorGetTableEntryIndex](#) as an input to this function. For example:

```
curColor = WinSetTextColor  
(UIColorGetTableEntryIndex(UIFieldText));
```

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [WinSetBackColor](#), [WinSetForeColor](#)

## WinSetTextColorRGB

**Purpose** Set the color to use for drawing characters in subsequent draw operations.

**Declared In** `Window.h`

**Prototype**  
`void WinSetTextColorRGB  
(const RGBColorType *newRgbP,  
RGBColorType *prevRgbP)`

**Parameters**

|             |                                                                        |
|-------------|------------------------------------------------------------------------|
| -> newRgbP  | Color to set; specify a value of type <a href="#">RGBColorType</a> .   |
| <- prevRgbP | Previous color; specify a value of type <a href="#">RGBColorType</a> . |

**Result** Returns nothing.

**Comments** This function takes new and previous [RGBColorType](#) arguments. It is okay to set newRgbP or prevRgbP to NULL. If an application only wants to get the current color, the newRgbP argument is set to NULL. If the application does not care about the previous color, prevRgbP can be set to NULL.

This function sets the `textColorRGB` field of the [DrawStateType](#) structure to the value specified by newRgbP. It then sets the index field of `textColorRGB` to the 8 bit system palette entry that most closely matches the RGB components. Finally, it sets the `textColor` index field of [DrawStateType](#) to this index value.

This function changes the current drawing state. If necessary, use [WinPushDrawState](#) to preserve the current drawing state before you set this function and use [WinPopDrawState](#) to restore it later.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [WinSetBackColorRGB](#), [WinSetForeColorRGB](#)

## WinSetUnderlineMode

|                    |                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the graphic state to enable or disable the underlining of characters.                                                                                                                                                           |
| <b>Declared In</b> | Window.h                                                                                                                                                                                                                            |
| <b>Prototype</b>   | UnderlineModeType WinSetUnderlineMode<br>(UnderlineModeType mode)                                                                                                                                                                   |
| <b>Parameters</b>  | <-> mode            New underline mode type; see<br><a href="#">UnderlineModeType</a> .                                                                                                                                             |
| <b>Result</b>      | Returns the previous underline mode type.                                                                                                                                                                                           |
| <b>Comments</b>    | This function changes the current drawing state. If necessary, use <a href="#">WinPushDrawState</a> to preserve the current drawing state before you set this function and use <a href="#">WinPopDrawState</a> to restore it later. |
| <b>See Also</b>    | <a href="#">WinDrawChars</a>                                                                                                                                                                                                        |

---

## **New** WinUnscaleCoord

|                    |                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a single coordinate from the active coordinate system to the standard coordinate system.                                                                     |
| <b>Declared In</b> | Window.h                                                                                                                                                             |
| <b>Prototype</b>   | Coord WinUnscaleCoord (Coord coord,<br>Boolean ceiling)                                                                                                              |
| <b>Parameters</b>  | -> coord            A coordinate in the active coordinate system.<br>-> ceiling           Pass true to round up, false to truncate the fractional part when scaling. |
| <b>Result</b>      | Returns the coordinate scaled to the standard coordinate system.                                                                                                     |

## Windows

### Window Functions

---

**Comments** This function converts a coordinate by dividing it by the coordinate scaling factor, truncating or rounding the result to an integer value depending on the value of `ceiling`.  
If the active coordinate system is `kCoordinatesStandard`, the returned coordinate is equal to the supplied coordinate.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [WinScaleCoord](#), [WinUnscalePoint](#), [WinUnscaleRectangle](#)

---

## New WinUnscalePoint

**Purpose** Convert a point from the active coordinate system to the standard coordinate system.

**Declared In** `Window.h`

**Prototype** `void WinUnscalePoint (PointType *pointP,  
Boolean ceiling)`

**Parameters**

|                               |                                                                                                                                                                                                                                                                                                  |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; pointP</code> | Pointer to a <code>PointType</code> structure that, before the call, should contain a point's coordinates using the active coordinate system. After this function is called the <code>PointType</code> structure contains the coordinates of the point scaled to the standard coordinate system. |
| <code>-&gt; ceiling</code>    | Pass <code>true</code> to round up, <code>false</code> to truncate the fractional part when scaling.                                                                                                                                                                                             |

**Result** Returns nothing. The coordinates of the point indicated by `pointP` are converted to the standard coordinate system.

**Comments** This function converts a point by dividing its x and y coordinates by the coordinate scaling factor, truncating or rounding the results to integer values depending on the value of `ceiling`. For instance,

the input coordinates (11, 13) are transformed to (6, 7) if the input values represent native coordinates on a handheld with a double-density screen and `ceiling` is set to `true`. If `ceiling` is set to `false`, the same input coordinates are transformed to (5, 6).

If the active coordinate system is `kCoordinatesStandard`, `pointP` is not changed by this function.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [WinScalePoint](#), [WinUnscaleCoord](#), [WinUnscaleRectangle](#)

---

## **New** WinUnscaleRectangle

**Purpose** Convert a rectangle from the active coordinate system to the standard coordinate system.

**Declared In** `Window.h`

**Prototype** `void WinUnscaleRectangle (RectangleType *rectP)`

**Parameters** `<-> rectP` Pointer to a `RectangleType` structure that, before the call, should contain a rectangle's coordinates using the active coordinate system. After this function is called the `RectangleType` structure contains the coordinates of the rectangle scaled to the standard coordinate system.

**Result** Returns nothing. The coordinates of the rectangle indicated by `rectP` are converted to the standard coordinate system.

**Comments** This function scales the rectangle's `topLeft` and `extent` points by dividing their `x` and `y` coordinates by the coordinate scaling factor. All values are then truncated, but if either `topLeft.x` or `extent.x` had a fractional part, `extent.x` is incremented by 1

## Windows

### Window Functions

---

(and, similarly, if either `topLeft.y` or `extent.y` had a fractional part, `extent.y` is incremented by 1).

If the active coordinate system is `kCoordinatesStandard`, `rectP` is not changed by this function.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [WinScaleRectangle](#), [WinUnscaleCoord](#), [WinUnscalePoint](#)

## WinValidateHandle

**Purpose** Return `true` if the specified handle references a valid window object.

**Declared In** `Window.h`

**Prototype** `Boolean WinValidateHandle (WinHandle winHandle)`

**Parameters** `-> winHandle` The handle to be tested.

**Result** Returns `true` if the specified handle references a non-NULL pointer to a window in the active window list, `false` if the handle references a window whose values are out of sync with the current system state.

**Comments** For debugging purposes only. Do not include this function in commercial applications.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FrmValidatePtr](#), [FrmRemoveObject](#)

## **WinWindowToDisplayPt**

- Purpose** Convert a window-relative coordinate to a display-relative coordinate.
- Declared In** `Window.h`
- Prototype** `void WinWindowToDisplayPt (Coord *extentX,  
Coord *extentY)`
- Parameters**
- `<-> extentX`      Pointer to x coordinate to convert.
  - `<-> extentY`      Pointer to y coordinate to convert.
- Result** Returns nothing.
- Comments** The coordinate passed is assumed to be relative to the draw window.
- See Also** [WinDisplayToWindowPt](#)

## **Windows**

### *Window Functions*

---

# Miscellaneous System Functions

---

This chapter describes miscellaneous system functions. The functions in this chapter are declared in the header files `Crc.h`, `DLServer.h`, `IntlMgr.h`, and `Localize.h`.

## Crc16CalcBlock

|                    |                                                                                 |                                |
|--------------------|---------------------------------------------------------------------------------|--------------------------------|
| <b>Purpose</b>     | Calculate the 16-bit CRC of a data block using the table lookup method.         |                                |
| <b>Declared In</b> | <code>Crc.h</code>                                                              |                                |
| <b>Prototype</b>   | <code>UInt16 Crc16CalcBlock (const void *bufP, UInt16 count, UInt16 crc)</code> |                                |
| <b>Parameters</b>  | <code>bufP</code>                                                               | Pointer to the data buffer.    |
|                    | <code>count</code>                                                              | Number of bytes in the buffer. |
|                    | <code>crc</code>                                                                | Seed crc value.                |
| <b>Result</b>      | A 16-bit CRC for the data buffer.                                               |                                |

### DlkControl

- Purpose** Perform an operation at the behest of the desktop software. Among other things, this function is used to return values to the conduit during the handling of [sysAppLaunchCmdHandleSyncCallApp](#).
- Declared In** DLServer.h
- Prototype** Err DlkControl (DlkCtlEnum op, void \*param1P, void \*param2P)
- Parameters**
- > op Desktop Link control code. Use `dlkCtlSendCallAppReply` when sending a result back to the conduit while handling a `sysAppLaunchCmdHandleSyncCallApp` launch code.
  - <-> param1P Pointer to the first parameter (operation-specific). For `dlkCtlSendCallAppReply`, this parameter should point to a [DlkCallAppReplyParamType](#) structure.
  - <-> param2P Pointer to the second parameter (operation-specific). For `dlkCtlSendCallAppReply`, this parameter should be set to NULL.
- Result** `errNone` if no error, or an error code if there was a problem during the call to `DlkControl`. In either case, place the value returned from `DlkControl` into the `replyErr` field of the `SysAppLaunchCmdHandleSyncCallAppType` structure when handling `sysAppLaunchCmdHandleSyncCallApp`.
- Comments** This function is needed to return data back to a conduit during the handling of [sysAppLaunchCmdHandleSyncCallApp](#). Set `param1P` to point to a [DlkCallAppReplyParamType](#) structure, as described below. See the [Example](#) on page 1249 for an illustration of how to handle `sysAppLaunchCmdHandleSyncCallApp`.

### DlkCallAppReplyParamType

**Prototype** `typedef struct DlkCallAppReplyParamType {  
 UInt16 pbSize;  
 UInt32 dwResultCode;  
 const void *resultP;  
 UInt32 dwResultSize;  
 void *dlRefP;  
 UInt32 dwReserved1;  
} DlkCallAppReplyParamType;`

|               |                           |                                                                                          |
|---------------|---------------------------|------------------------------------------------------------------------------------------|
| <b>Fields</b> | <code>pbSize</code>       | Size of this parameter block. Set it to <code>sizeof (DlkCallAppReplyParamType)</code> . |
|               | <code>dwResultCode</code> | Result code to be returned to the remote caller.                                         |
|               | <code>resultP</code>      | Pointer to result data.                                                                  |
|               | <code>dwResultSize</code> | Size of result data block (number of bytes).                                             |
|               | <code>dlRefP</code>       | Desktop Link reference pointer from <code>SysAppLaunchCmdHandleSyncCallAppType</code> .  |
|               | <code>dwReserved1</code>  | Reserved. Set to <code>NULL</code> .                                                     |

**Example** The `SysAppLaunchCmdHandleSyncCallAppType` structure that accompanies the [sysAppLaunchCmdHandleSyncCallApp](#) launch code contains all of the information passed into `SyncCallRemoteModule` on the desktop as well as the necessary fields to pass the result pack to the desktop. At the end of your `sysAppLaunchCmdHandleSyncCallApp` launch code handler, you'll need to send a [DlkCallAppReplyParamType](#) reply structure back to the device using `DlkControl`.

---

```
#include <DLServer.h>
...
case sysAppLaunchCmdHandleSyncCallApp:
{
    SysAppLaunchCmdHandleSyncCallAppType *theCommandPtr;
    DlkCallAppReplyParamType theReplyParams;
    CharPtr theReplyBuffer = "SUCCESS";

    // Cast the cmdPBP to a SysAppLaunchCmdHandleSyncCallAppType
    // pointer so that we can work with it.
    theCommandPtr = (SysAppLaunchCmdHandleSyncCallAppType*) cmdPBP;
```

## Miscellaneous System Functions

---

```
// Do whatever work is necessary here.  If you set the m_wActionCode
// field in your CCallModuleParams class on the desktop, then you
// can handle that code by looking at the action field of theCommandPtr
// (i.e.) if (theCommandPtr->action == 1)

// Create the reply to send back to the desktop

// First clear out all the fields.  This is necessary so that the reserved
// fields are set to NULL.
MemSet( &theReplyParams, sizeof(DlkCallAppReplyParamType), 0 );

// Set the size of the reply.  This is required.
theReplyParams.pbSize = sizeof(DlkCallAppReplyParamType);

// Set the result code.  Normally this will be set to zero unless you want
// to send an error code back to the desktop.
theReplyParams.dwResultCode = 0;

// Fill in the reply buffer and buffer length
theReplyParams.resultP = theReplyBuffer;
theReplyParams.dwResultSize = StrLen(theReplyBuffer) + 1;

// Fill in the DL reference pointer.  This is required.
theReplyParams.dlRefP = theCommandPtr->dlRefP;

// Set the handled field to true.  This is required to let the desktop
// know that the sysAppLaunchCmdHandleSyncCallApp was handled.  If you
// don't set this to true, the call to SyncCallRemoteModule will return
// SYNCERR_UNKNOWN_REQUEST.
theCommandPtr->handled = true;

// Finally, set the replyErr field by passing the reply parameters to
// DlkControl.  This is required for the DLServer to properly handle the
// reply request.
theCommandPtr->replyErr = DlkControl (dlkCtlSendCallAppReply,
    &theReplyParams, NULL);

break;
}
```

---

[Table 55.1](#) and [Table 55.2](#) list some important mappings from the CCallModuleParams class on the desktop to the SysAppLaunchCmdHandleSyncCallAppType and DlkCallAppReplyParamType structures on the handheld.

**Table 55.1 CCallModuleParams to SysAppLaunchCmdHandleSyncCallAppType mapping**

| <b>CCallModuleParams</b> | <b>SysAppLaunchCmdHandleSyncCallAppType</b> |
|--------------------------|---------------------------------------------|
| m_wActionCode            | action                                      |
| m_dwParamSize            | dwParamSize                                 |
| m_pParam                 | paramP                                      |

**Table 55.2 CCallModuleParams to DlkCallAppReplyParamType mapping**

| <b>CCallModuleParams</b> | <b>DlkCallAppReplyParamType</b> |
|--------------------------|---------------------------------|
| m_dwResultBufSize        | dwResultSize                    |
| m_pResultBuf             | resultP                         |
| m_dwResultCode           | dwResultCode                    |

## DlkGetSyncInfo

**Purpose** Get the sync info managed by Desktop Link. This function is often used to obtain the user name on the handheld.

**Declared In** DLServer.h

**Prototype** Err DlkGetSyncInfo (UInt32 \*succSyncDateP, UInt32 \*lastSyncDateP, DlkSyncStateType \*syncStateP, Char \*nameBufP, Char \*logBufP, Int32 \*logLenP)

**Parameters** <- succSyncDateP  
 Pointer to the location where the date of the last successful sync is stored. Supply NULL for this parameter if this date isn't needed.

## Miscellaneous System Functions

---

|                                  |                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- lastSyncDateP</code> | Pointer to the location where the date of the last sync, successful or otherwise, is stored. Supply <code>NULL</code> for this parameter if this date isn't needed.                                                                                                                                                                                                                         |
| <code>&lt;- syncStateP</code>    | Pointer to a <code>DlkSyncStateType</code> enum into which the state of the last sync is stored. Supply <code>NULL</code> for this parameter if the state information isn't needed. See the Comments, below, for a description of this enum.                                                                                                                                                |
| <code>&lt;- nameBufP</code>      | Pointer to a string buffer into which the null-terminated handheld user name is stored. This string buffer must have been preallocated to be at least <code>dlkUserNameBufSize</code> bytes in length. Supply <code>NULL</code> for this parameter if the user name isn't needed.                                                                                                           |
| <code>&lt;- logBufP</code>       | Pointer to a string buffer into which the sync log text, null-terminated, is stored. Supply <code>NULL</code> for this parameter if the log text isn't needed. If you supply a valid pointer for this parameter, you must specify the preallocated buffer length using the <code>logLenP</code> parameter; the returned log text will be truncated, if necessary, to fit within the buffer. |
| <code>&lt;-&gt; logLenP</code>   | Pointer to the log buffer size. If <code>logBufP</code> is not <code>NULL</code> , on entry you must set this value to the size of the <code>logBufP</code> buffer. When this function returns, this value indicates the actual length of the log text, not counting the null terminator.                                                                                                   |

**Result** Returns `errNone` if no error, or `dlkErrMemory` if the Desktop Link preferences resource couldn't be locked.

**Comments** The state information returned through `syncStateP` has one of the values defined by the `DlkSyncStateType` enum:

```
typedef enum DlkSyncStateType {
    dlkSyncStateNeverSynced = 0,
    dlkSyncStateInProgress,
```

## Miscellaneous System Functions

---

```
    dlkSyncStateLostConnection,  
    dlkSyncStateLocalCan,  
    dlkSyncStateRemoteCan,  
    dlkSyncStateLowMemoryOnTD,  
    dlkSyncStateAborted,  
    dlkSyncStateCompleted,  
    dlkSyncStateIncompatibleProducts,  
    dlkSyncStateNPOD  
} DlkSyncStateType;
```

---

| <b>Value</b>                            | <b>Description</b>                                        |
|-----------------------------------------|-----------------------------------------------------------|
| <code>dlkSyncStateNeverSynced</code>    | The handheld has never been synced.                       |
| <code>dlkSyncStateInProgress</code>     | A sync is currently in progress.                          |
| <code>dlkSyncStateLostConnection</code> | The connection was lost during sync.                      |
| <code>dlkSyncStateLocalCan</code>       | Sync was cancelled by the user on the handheld.           |
| <code>dlkSyncStateRemoteCan</code>      | Sync was cancelled by the user from the desktop.          |
| <code>dlkSyncStateLowMemoryOnTD</code>  | Sync ended due to a low memory condition on the handheld. |
| <code>dlkSyncStateAborted</code>        | Sync was aborted for some other reason.                   |
| <code>dlkSyncStateCompleted</code>      | Sync completed normally.                                  |

## Miscellaneous System Functions

---

| Value                                         | Description                                                                                                                                  |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dlkSyncStateIncompatibleProducts</code> | Sync ended because the desktop HotSync product is incompatible with this version of the handheld HotSync.                                    |
| <code>dlkSyncStateNPOD</code>                 | The sync could not take place because the handheld has a 4.0-style password but the desktop hasn't yet been updated to a compatible version. |

**Example** This function is most often used to obtain the handheld user name. The following code excerpt shows how to do this (for clarity, error-checking has been omitted):

---

```
MemHandle nameH;
char *nameP;

// Allocate a buffer for the user name
nameH = MemHandleNew(dlkUserNameBufSize);
nameP = MemHandleLock(nameH);

// Obtain the user's name
DlkGetSyncInfo(NULL, NULL, NULL, nameP, NULL, NULL);

// ... Do something with the user name here ...

// Now that we're done with the user name, free the buffer
MemPtrUnlock(nameP);
```

---

**Compatibility** The `dlkSyncStateIncompatibleProducts` enum value was added in Palm OS 3.0. The `dlkSyncStateNPOD` enum value was added in Palm OS 4.0.

## IntlGetRoutineAddress

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the address of an international manager or text manager function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b>   | <code>IntlMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>     | <pre>void *IntlGetRoutineAddress<br/>(IntlSelector inSelector)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>    | -> <code>inSelector</code> One of the routine selectors defined in <code>IntlMgr.h</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Result</b>        | Returns the address of the corresponding function. Returns <code>NULL</code> if an invalid routine selector is passed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Comments</b>      | <p>Use this function for performance reasons. It returns the address of an international manager or text manager function. You can then use this address to call the function without having to go through the international manager's trap dispatch table. This function is mostly useful for optimizing the performance of text manager routines that are called in a tight loop.</p> <p>You might also use this function to check for the presence of newer international manager and text manager functions. If the result is <code>NULL</code>, the function is not implemented on this device.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| -> iSelector         | One of the routine selectors defined in IntlMgr.h.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                                    |             |                                                                                 |
| -> iProcPtr          | Pointer to a function that the routine identified by iSelector should point to.                                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                                                    |             |                                                                                 |
| <b>Result</b>        | Returns errNone if no error, or intlErrInvalidSelector if iSelector does not refer to a valid international manager or text manager routine.                                                                                                                                                                                                                                                                                                                                                                              |              |                                                    |             |                                                                                 |
| <b>Comments</b>      | <p>This function is useful for patching an international or text manager function. Normally only a locale module would need to patch one of these functions.</p> <hr/> <p><b>WARNING!</b> If your application patches an international manager function using this function, you <b>must</b> remove the patch before your application exits. Do <b>not</b> use this mechanism to permanently patch international manager functions as it may cause unpredictable results for the system and other applications.</p> <hr/> |              |                                                    |             |                                                                                 |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present. If <a href="#">5.0 New Feature Set</a> is present this function is unimplemented.                                                                                                                                                                                                                                                                                                                                                                     |              |                                                    |             |                                                                                 |
| <b>See Also</b>      | <a href="#">IntlGetRoutineAddress</a> , <a href="#">SysSetTrapAddress</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |                                                    |             |                                                                                 |

## LocGetNumberSeparators

|                      |                                                                                                                                                                                                                                                        |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Get localized number separators.                                                                                                                                                                                                                       |
| <b>Declared In</b>   | Localize.h                                                                                                                                                                                                                                             |
| <b>Prototype</b>     | <pre>void LocGetNumberSeparators<br/>(NumberFormatType numberFormat,<br/>Char *thousandSeparator, Char *decimalSeparator)</pre>                                                                                                                        |
| <b>Parameters</b>    | <p>-&gt; numberFormat The format to use (see <a href="#">NumberFormatType</a>).</p> <p>&lt;- thousandSeparator<br/>The character used for the thousands separator.</p> <p>&lt;- decimalSeparator<br/>The character used for the decimal separator.</p> |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                       |
| <b>Comments</b>      | The format to use is stored in the system preferences. You can obtain it by passing prefNumberFormat to <a href="#">PrefGetPreference</a> .                                                                                                            |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                    |
| <b>See Also</b>      | <a href="#">StrLocalizeNumber</a> , <a href="#">StrDeLocalizeNumber</a> , “ <a href="#">Localized Applications</a> ” in the <i>Palm OS Programmer’s Companion</i> , vol. I                                                                             |

---

### PceNativeCall

- Purpose** Call a native ARM or Windows NT function from code running in the PACE (68k) environment.
- Declared In** `PceNativeCall.h`
- Prototype** `UInt32 PceNativeCall(  
NativeFuncType *nativeFuncP, void *userDataP)`
- Parameters**
- |                                  |                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; nativeFuncP</code>   | On a handheld with an ARM processor, this is a pointer to the ARM function to be executed. On Palm OS Simulator, this is a pointer to the name of a DLL and the name of the entry point within that DLL that is to be executed, separated by a null character and terminated with a null character. See the Comments, below, for more details on the format of this argument. |
| <code>&lt;-&gt; userDataP</code> | Pointer to an application-specific block of data that is passed to the ARM function. This block has no specific alignment requirements; it needn't be aligned on a 16- or 32-bit boundary. Note that your ARM function may impose specific alignment requirements, however.                                                                                                   |
- Result** The return value of the specified ARM function is returned by `PceNativeCall`. This value is placed in both the A0 and D0 registers in the emulated 68k CPU, allowing `PceNativeCall` to support both pointer and immediate return value conventions.
- Comments** Applications that employ `PceNativeCall` won't work on handhelds running a version of Palm OS prior to Palm OS 5. Before calling `PceNativeCall`, your application must verify the underlying processor type, since the calling convention is different on Palm OS Simulator. See "[Calling an ARM Function](#)" on page 340 of *Palm OS Programmer's Companion*, vol. I for more information and an example.

`PceNativeCall` byte-swaps the parameter pointer and return value as appropriate for the Dragonball-to-ARM transition. This allows you to dereference `userDataP` directly from your ARM code. Because the operating system has no knowledge of the structure of the parameter block, however, it performs no byte-swapping within this block. Your ARM code must do this as necessary for your application (see "[Accessing 68K Data From an ARM Function](#)" on page 342 of the *Palm OS Programmer's Companion*, vol. I for more information).

On Palm OS Simulator, rather than passing a pointer to a block of ARM code in `nativeFuncP`, you instead pass a pointer to the name of a DLL and the name of the function within that DLL that is to be executed. These two names must be separated by a null character, and the entire sequence must be terminated by a null character. For example, to load the DLL found at `C:\TEST_DLL\Debug\Simple.dll` and call the function `TestNativeCall` within that DLL, you might pass a pointer to the following character string literal:

```
"C:\\TEST_DLL\\Debug\\Simple.dll\\0TestNativeCall"
```

Note that if you don't supply an absolute path, Simulator looks for the DLL in (or relative to) the directory from which `PalmSim.exe` is running. Thus, if the DLL is located in the same directory as `PalmSim.exe`, you can call the above function with:

```
"Simple.dll\\0TestNativeCall"
```

On release ROMs, `PceNativeCall` fails silently if `nativeFuncP` is NULL. On debug ROMs, it generates an error. All other pointers are treated as valid code and followed. If `nativeFuncP` is invalid, the processor will try to execute the code anyway and will eventually generate an error.

---

**NOTE:** The call to your native function is guaranteed to be made from ARM mode.

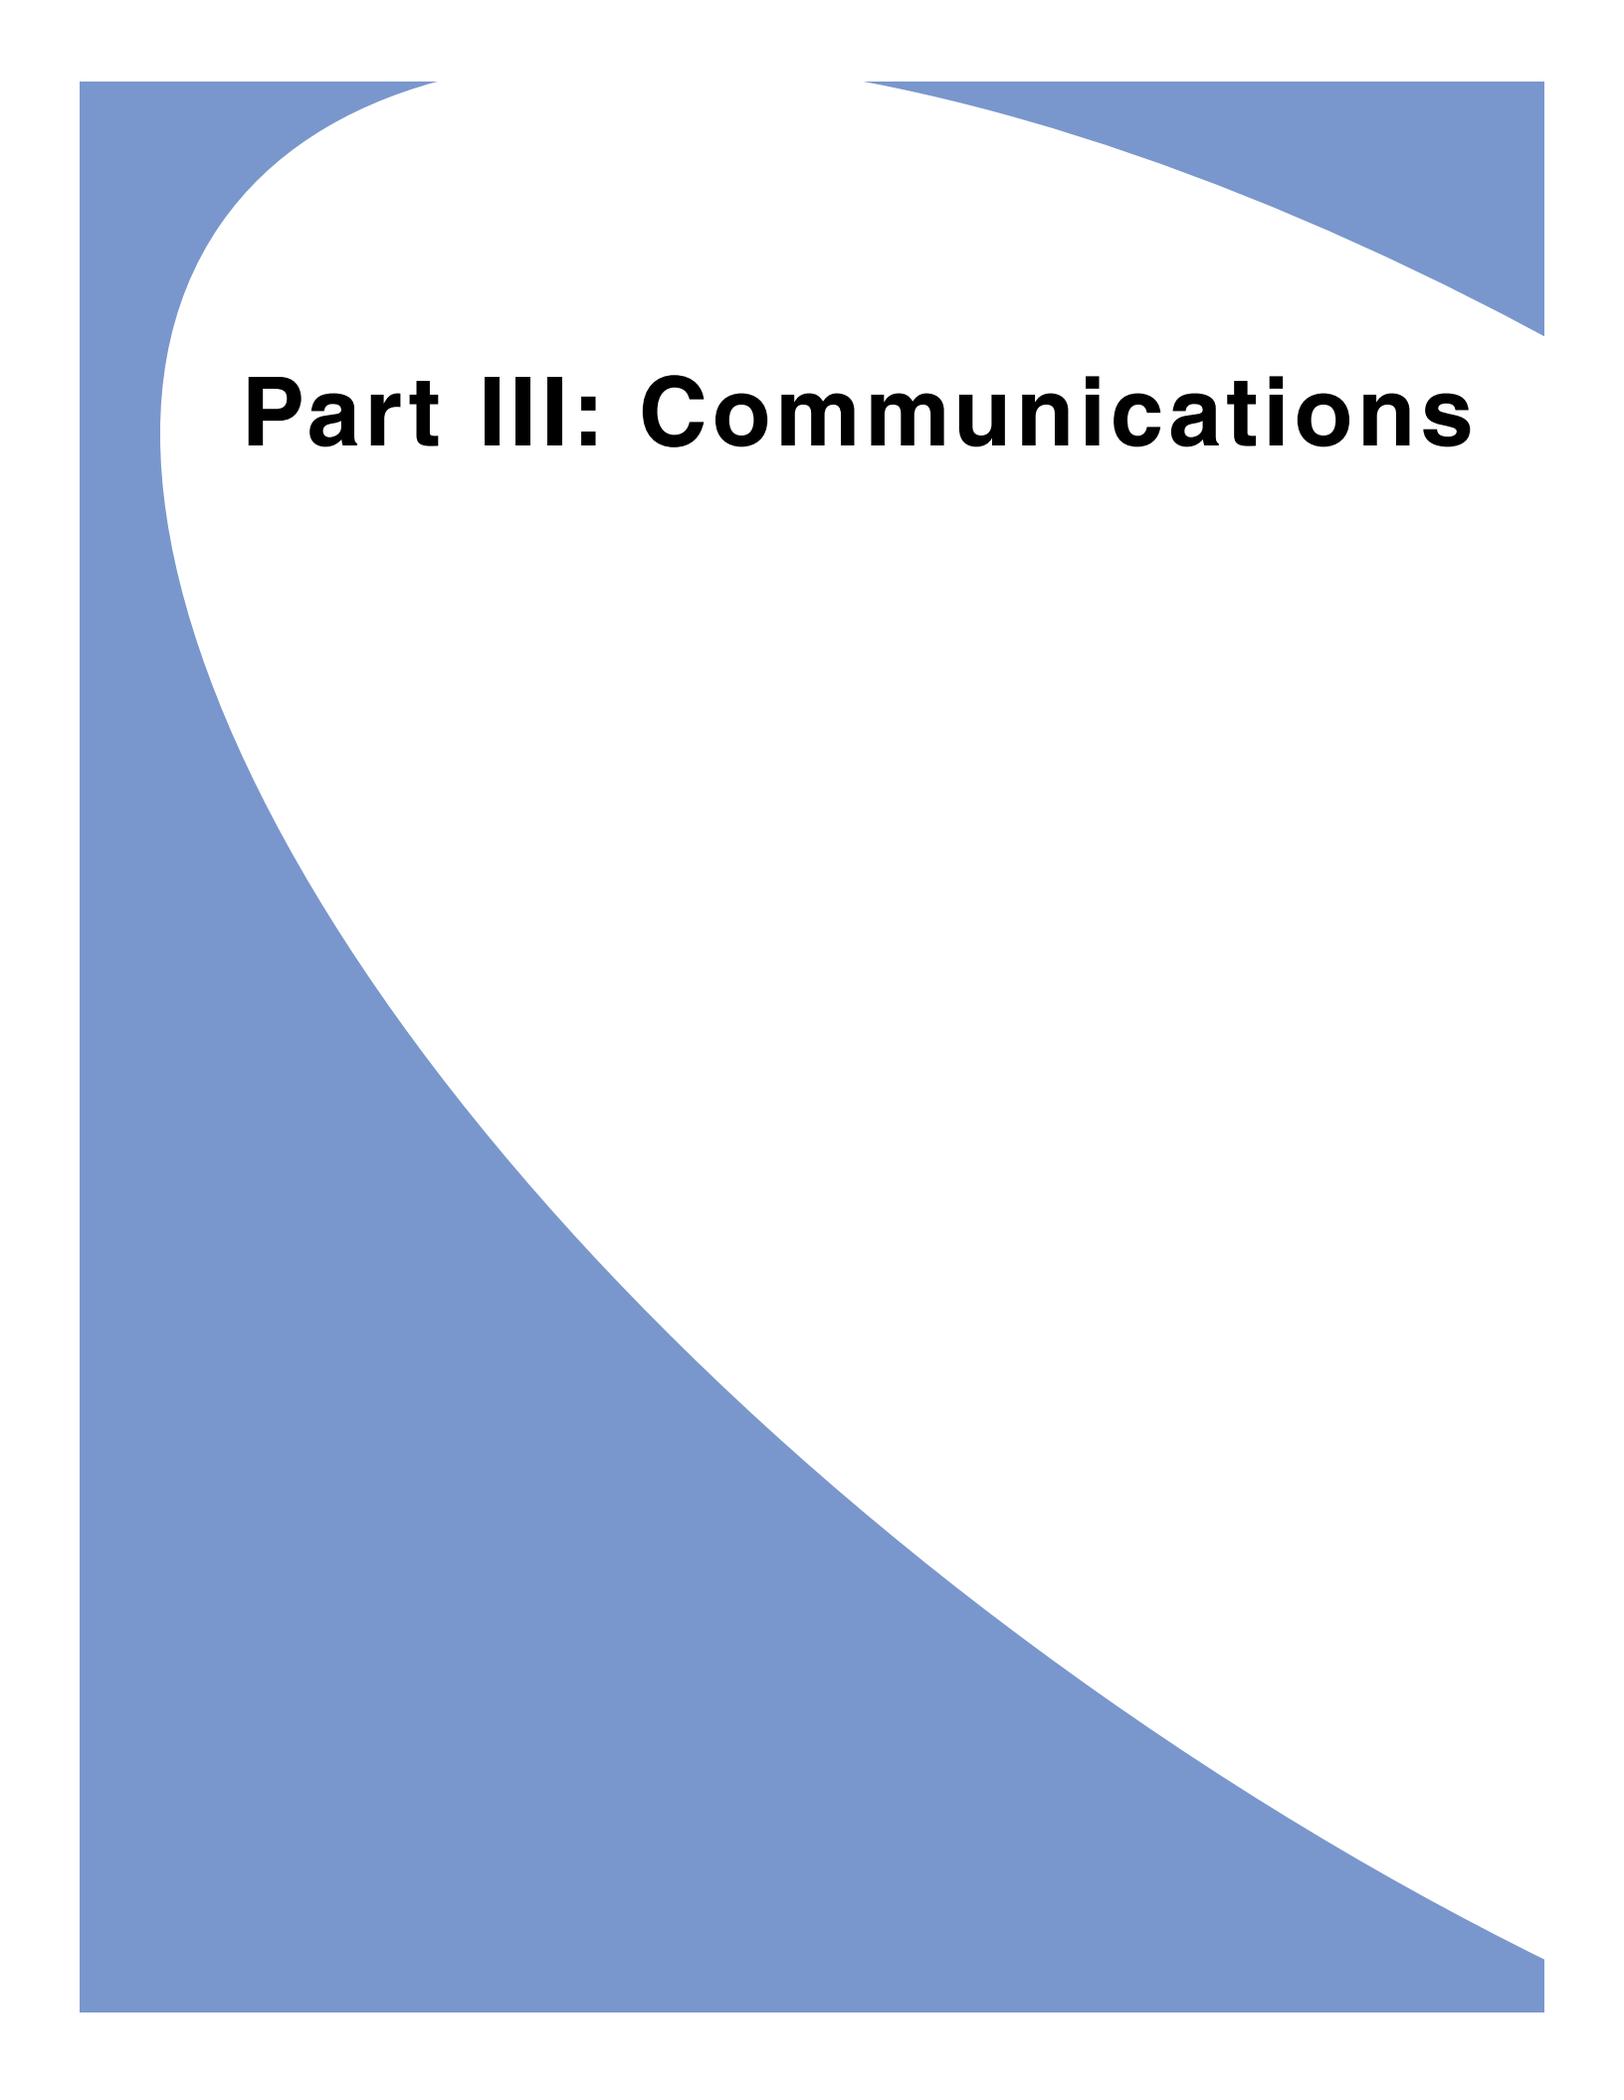

---

For more information on how the ARM code should be structured and how to call back and forth between the PACE and ARM environments, see "[ARM-Native Functions](#)" on page 339 of the *Palm OS Programmer's Companion*, vol. I.

## Miscellaneous System Functions

---

**Compatibility**    Implemented only if [5.0 New Feature Set](#) is present.

# **Part III: Communications**

# Connection Manager

---

The Connection Manager allows other applications to access, add, and delete connection profiles contained in the Connection panel.

This chapter provides reference material for the Connection Manager API declared in the header file `ConnectionMgr.h`:

- [Connection Manager Constants](#)
- [Connection Manager Functions](#)

For more information on the Connection Manager, see the chapter “[Serial Communication](#)” on page 89 in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Connection Manager Data Types

### CncProfileID

The `CncProfileID` type uniquely identifies a connection profile within the Connection Manager profile database. You pass this ID as a parameter to several of the Connection Manager functions. You can obtain a connection’s profile ID using [CncProfileGetIDFromName](#) or [CncProfileGetIDFromIndex](#).

```
typedef UInt32 CncProfileID
```

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

## Connection Manager Constants

### Profile Parameter Constants

The Connection Manager defines the following constants to represent individual parameters in the preinstalled connection profiles. Not all parameters work for all types of profiles.

## Connection Manager

### Connection Manager Constants

---

| Parameter Name                            | Parameter Type      | Description                                                                                                                                                                                                                       |
|-------------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kCncParamBaud</code>                | <code>UInt32</code> | The baud rate to use for the connection.                                                                                                                                                                                          |
| <code>kCncParamBluetoothDeviceAddr</code> | <code>buffer</code> | The 48-bit address ( <code>BD_ADDR</code> ) of the device that the handheld is connected to through the Bluetooth port. This parameter is only valid if <code>kCncParamPort</code> specifies the Bluetooth port.                  |
| <code>kCncParamBluetoothDeviceName</code> | <code>string</code> | The name of the device that the handheld is connected to through the Bluetooth port. The device name uses the UTF-8 character encoding. This parameter is only valid if <code>kCncParamPort</code> specifies the Bluetooth port.  |
| <code>kCncParamCountryIndex</code>        | <code>UInt16</code> | The index into the list of strings returned by <code>kCncParamIntlModemCountryStringList</code> and <code>kCncParamIntlModemResetStringList</code> that provides the name of the country and the reset commands for this profile. |
| <code>kCncParamDeviceKind</code>          | <code>UInt16</code> | The type of connection being made (general serial connection, connection to a modem, connection to a phone, and so on). This value is one of the <a href="#">Device Kind Constants</a> .                                          |
| <code>kCncParamDialingMode</code>         | <code>UInt8</code>  | For modem profiles, the dialing mode. 1 for Pulse dialing, 0 for TouchTone.                                                                                                                                                       |

---

|                                    |                     |                                                                                                                                                                                                                                   |
|------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kCncParamCountryIndex</code> | <code>UInt16</code> | The index into the list of strings returned by <code>kCncParamIntlModemCountryStringList</code> and <code>kCncParamIntlModemResetStringList</code> that provides the name of the country and the reset commands for this profile. |
| <code>kCncParamDeviceKind</code>   | <code>UInt16</code> | The type of connection being made (general serial connection, connection to a modem, connection to a phone, and so on). This value is one of the <a href="#">Device Kind Constants</a> .                                          |
| <code>kCncParamDialingMode</code>  | <code>UInt8</code>  | For modem profiles, the dialing mode. 1 for Pulse dialing, 0 for TouchTone.                                                                                                                                                       |

## Connection Manager

### Connection Manager Constants

---

| Parameter Name                      | Parameter Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamIntlModemCountryStringList | buffer         | <p>For modem profiles, a data buffer containing a list of possible countries. This list contains the countries in which the modem can operate and is shown in the Connection panel Details form for this profile. The selected country controls the dialing prefix and the modem reset string. The kCncParamCountryIndex parameter specifies the country selected from this list.</p> <p>The data buffer contains a packed block of null-terminated strings, each containing a country name. The first 16 bits of the data buffer (a UInt16 value) tells how many strings are contained in the block. You can use <a href="#">SysFormPointerArrayToString</a> to convert the data buffer into an array of strings.</p> <p>Because this parameter value has a variable size, you must first call <a href="#">CncProfileSettingGet</a> with a NULL data pointer to obtain the correct size.</p> |
| kCncParamIntlModemResetStringList   | buffer         | <p>For modem profiles, a data buffer containing possible reset strings. The kCncParamCountryIndex parameter specifies which reset string from this list is to be used. The actual string used is itself stored in the kCncParamResetString parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter Name                  | Parameter Type | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                 |                | <p>The data buffer contains a packed block of null-terminated strings, each containing a reset string. The first 16 bits of the data buffer (a <code>UInt16</code> value) tells how many strings are contained in the block. You can use <a href="#">SysFormPointerArrayToString</a> to convert the data buffer into an array of strings.</p> <p>Because this parameter value has a variable size, you must first call <a href="#">CncProfileSettingGet</a> with a <code>NULL</code> data pointer to obtain the correct size.</p> |
| <code>kCncParamInvisible</code> | system flag    | If <code>true</code> , the profile is hidden from the user. If <code>false</code> , the profile is visible. This parameter is not currently used.                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>kCncParamLocked</code>    | system flag    | If <code>true</code> , the profile is locked so that the user cannot edit it. If <code>false</code> , the profile can be edited. This parameter can be set by profiles, such as phone profiles, created by third party utilities.                                                                                                                                                                                                                                                                                                 |
| <code>kCncParamName</code>      | string         | The name of the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>kCncParamNoDetails</code> | system flag    | If <code>true</code> , the profile details should not be displayed. If <code>false</code> , they can be displayed. The profile details are the parameters that appear in the Details form of the Connection panel.                                                                                                                                                                                                                                                                                                                |

## Connection Manager

### Connection Manager Constants

---

| Parameter Name                            | Parameter Type      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kCncParamNonEditable</code>         | system flag         | <p>If <code>true</code>, the Connection panel's Edit form should be suppressed for this profile. If <code>false</code>, the Edit form can be displayed.</p> <p>This parameter differs from <code>kCncParamLocked</code> and <code>kCncParamReadOnly</code> in that it causes an alert to be displayed if the user taps the Edit button. The other parameters allow the Edit form to be displayed but do not allow changes to be made. Also, a non-editable profile can be deleted, but a read-only or locked profile cannot.</p> |
| <code>kCncParamPort</code>                | <code>UInt32</code> | The logical, physical, or virtual port identifier. See " <a href="#">Port Constants</a> " on <a href="#">page 1557</a> in the " <a href="#">Serial Manager</a> " chapter for more information.                                                                                                                                                                                                                                                                                                                                   |
| <code>kCncParam_PSDCreator</code>         | <code>UInt32</code> | For phone profiles, the creator ID of the phone driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>kCncParam_PSDName</code>            | string              | For phone profiles, the name of the phone driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>kCncParam_PSDParameterBuffer</code> | buffer              | For phone profiles, a data buffer containing any necessary data that the phone driver needs to store. This parameter typically holds data that is set using the Details form of the Connection panel.                                                                                                                                                                                                                                                                                                                            |
| <code>kCncParam_PSDType</code>            | <code>UInt32</code> | For phone profiles, the database type for the phone driver.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Parameter Name</b>                 | <b>Parameter Type</b> | <b>Description</b>                                                                                                                                                                                                                                    |
|---------------------------------------|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kCncParamReadOnly</code>        | system flag           | If <code>true</code> , the profile is read-only and cannot be edited. If <code>false</code> , the profile can be edited. This parameter is only intended to be used by profiles pre-installed in the Palm OS.                                         |
| <code>kCncParamReceiveTimeOut</code>  | UInt32                | For phone profiles, the number of milliseconds to wait for a response from the phone. This time-out value is used by telephony functions that don't need to access the network (for example, the function <a href="#">TelNwkGetSelectedNetwork</a> ). |
| <code>kCncParamResetString</code>     | string                | For modem and phone profiles, the reset string. For modem profiles, this is one of the strings in <code>kCncParamIntlModemResetStringList</code> .                                                                                                    |
| <code>kCncParamSerialPortFlags</code> | UInt32                | For phone profiles, bit flags that correspond to various serial port hardware settings. See " <a href="#">Serial Settings Constants</a> " on page 1560 for more information.                                                                          |
| <code>kCncParamSystemFlags</code>     | UInt32                | A bit flag representing all system flags. Currently, only bits 0 through 4 have a meaning. These correspond to the read-only bit, the invisible bit, the noneditable bit, the no details bit, and the locked bit, respectively.                       |
| <code>kCncParamTimeOut</code>         | UInt32                | The amount of time in milliseconds to wait for a response when CTS is unasserted and hardware flow control is on.                                                                                                                                     |

## Connection Manager

### Connection Manager Constants

---

| Parameter Name     | Parameter Type | Description                                                                                                                       |
|--------------------|----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| kCncParamTTCreator | UInt32         | For phone profiles, the creator ID of the telephony task used by the phone driver.                                                |
| kCncParamTTType    | UInt32         | For phone profiles, the database type for the telephony task used by the phone driver.                                            |
| kCncParamVersion   | UInt8          | The version of the Connection Manager API under which this profile was created. The current version number is kCncProfileVersion. |
| kCncParamVolume    | UInt16         | For modem profiles, the modem volume.                                                                                             |

---

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

### Profile Parameter Size Constants

The size constants specify the size of each of the predefined parameters described in "[Profile Parameter Constants](#)." The following table lists the parameter name, the size of its value, and the size constant that gives this size. These size constants are suitable for passing to [CncProfileSettingGet](#) and [CncProfileSettingSet](#).

| Profile Parameter Name       | Size | Size Constant                       |
|------------------------------|------|-------------------------------------|
| kCncParamBaud                | 32   | kCncParamBaudSize                   |
| kCncParamBluetoothDeviceAddr | 8    | kCncParamBluetoothDeviceAddrSize    |
| kCncParamBluetoothDeviceName | 249  | kCncParamBluetoothDeviceNameMaxSize |
| kCncParamCountryIndex        | 16   | kCncParamCountryIndexSize           |

---

| <b>Profile Parameter Name</b> | <b>Size</b> | <b>Size Constant</b>              |
|-------------------------------|-------------|-----------------------------------|
| kCncParamDeviceKind           | 16          | kCncParamDeviceKindSize           |
| kCncParamDialingMode          | 8           | kCncParamDialingModeSize          |
| kCncParamFlowControl          | 16          | kCncParamFlowControlSize          |
| kCncParamInitString           | 81          | kCncParamInitStringMaxSize        |
|                               | 81          | kCncProfileUsualInitStringsSize   |
| kCncParamInvisible            | 8           | kCncParamInvisibleSize            |
| kCncParamLocked               | 8           | kCncParamLockedSize               |
| kCncParamName                 | 22          | kCncParamNameMaxSize              |
|                               | 22          | kCncProfileNameSize               |
| kCncParamNoDetails            | 8           | kCncParamNoDetailsSize            |
| kCncParamNonEditable          | 8           | kCncParamNonEditableSize          |
| kCncParamPort                 | 32          | kCncParamPortSize                 |
| kCncParam_PSDCreator          | 32          | kCncParam_PSDCreatorSize          |
| kCncParam_PSDName             | 32          | kCncParam_PSDNameSize             |
| kCncParam_PSDType             | 32          | kCncParam_PSDTypeSize             |
| kCncParamReadOnly             | 8           | kCncParamReadOnlySize             |
| kCncParamReceiveTimeOut       | 32          | kCncParamReceiveTimeOutSize       |
| kCncParamResetString          | 81          | kCncParamResetStringMaxSize       |
|                               | 8           | kCncProfileClassicResetStringSize |
|                               | 81          | kCncProfileUsualResetStringSize   |
| kCncParamSystemFlags          | 32          | kCncParamSystemFlagsSize          |
| kCncParamTimeOut              | 32          | kCncParamTimeOutSize              |

## Connection Manager

### Connection Manager Constants

---

| Profile Parameter Name | Size | Size Constant          |
|------------------------|------|------------------------|
| kCncParamTTCreator     | 32   | kCncParamTTCreatorSize |
| kCncParamTTType        | 32   | kCncParamTTTypeSize    |
| kCncParamVersion       | 8    | kCncParamVersionSize   |
| kCncParamVolume        | 16   | kCncParamVolumeSize    |

---

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

### Device Kind Constants

The device kind constants specify the type of connection being made. You specify the type of connection by defining a value for the kCncParamDeviceKind parameter using [CncProfileSettingSet](#).

| Constant                   | Value | Description                                |
|----------------------------|-------|--------------------------------------------|
| kCncDeviceKindSerial       | 0     | The connection is through the serial port. |
| kCncDeviceKindModem        | 1     | The connection is to a modem.              |
| kCncDeviceKindPhone        | 2     | The connection is to a phone.              |
| kCncDeviceKindLocalNetwork | 3     | The connection is to a LAN.                |

---

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

### Profile Parameter Types

The parameter type constants specify the type of value stored for a parameter in a connection profile. If you define a new parameter using [CncDefineParamID](#), you must use one of these constants to specify the type of data the parameter stores. The macro [CncGetParamType](#) can return this information for any parameter in the profile.

| <b>Constant</b>     | <b>Value</b> | <b>Description</b>                                                                                                                                                                                                                                                       |
|---------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kCncParamSystemFlag | 0x00         | A system flag parameter. The Connection Manager can store up to 32 system flags. Flags are stored in a single bit and returned as a UInt8 value. The entire system flags word can be returned if you pass kCncParamSystemFlags to <a href="#">CncProfileSettingGet</a> . |
| kCncParamUInt8      | 0x01         | A UInt8 parameter.                                                                                                                                                                                                                                                       |
| kCncParamUInt16     | 0x02         | A UInt16 parameter.                                                                                                                                                                                                                                                      |
| kCncParamUInt32     | 0x03         | A UInt32 parameter.                                                                                                                                                                                                                                                      |
| kCncParamString     | 0x04         | A string parameter.                                                                                                                                                                                                                                                      |
| kCncParamBuffer     | 0x05         | A generic block of data.                                                                                                                                                                                                                                                 |

**Compatibility** Defined only if [Connection Manager Feature Set](#) is present.

## Connection Manager Functions

### CncAddProfile

**Purpose** Adds a profile to the Connection Manager.

**Declared In** ConnectionMgr.h

**Prototype** `Err CncAddProfile (Char *name, UInt32 port, UInt32 baud, UInt16 volume, UInt16 handShake, const Char *initString, const Char *resetString, Boolean isModem, Boolean isPulse)`

**Parameters** <-> name Pointer to the profile name to be added. If the name is already taken in the Connection panel then a duplication number is appended to it. The name added is returned here.

## Connection Manager

### Connection Manager Functions

---

|                |                                                                                                                                                                                                        |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> port        | The port identification used by the profile. See <a href="#">“Specifying the Port”</a> on page 100 of the <i>Palm OS Programmer’s Companion</i> , vol. II, <i>Communications</i> for more information. |
| -> baud        | The baud rate used by the profile.                                                                                                                                                                     |
| -> volume      | The volume setting for the device (for Modem only).                                                                                                                                                    |
| -> handShake   | Flow control setting (hardware handshaking). 0 specifies automatic (on at speeds > 2400 baud), 1 specifies always on, and 2 specifies always off.                                                      |
| -> initString  | Pointer to the initialization string used by a modem (for Modem only).                                                                                                                                 |
| -> resetString | Pointer to the reset string used by a modem (for Modem only).                                                                                                                                          |
| -> isModem     | true if Modem, false if Direct.                                                                                                                                                                        |
| -> isPulse     | true if Pulse dial, false if TouchTone.                                                                                                                                                                |

|               |                        |                                                            |
|---------------|------------------------|------------------------------------------------------------|
| <b>Result</b> | errNone                | No error.                                                  |
|               | cncErrAddProfileFailed | The add operation failed.                                  |
|               | cncErrProfileListFull  | The add operation failed because the profile list is full. |
|               | cncErrConDBNotFound    | The connection database is missing.                        |

**Comments** All profiles within the Connection Manager must have a unique name. The Connection Manager tries to append a duplication number to the end of the name if you specify a name that is already taken.

There is a maximum limit to the number of profiles that can be maintained by the Connection Manager. If the limit is passed, an error is returned and that profile will not be added.

Profiles that do not need certain fields may pass NULL in the place of a value.

**Compatibility** Implemented only if [New Serial Manager Feature Set](#) is present. If [Connection Manager Feature Set](#) is present, use [CncProfileCreate](#) instead of using this function. CncAddProfile is still supported for backward compatibility. In Palm OS 4.0 and higher, the maximum number of profiles that can be defined has greatly increased.

**Example**

```
AddMyProfile()
{
    Char *myConNameP;
    Err err;

    myConNameP = MemPtrNew(cncProfileNameSize);

    StrCopy(myConNameP, "Foobar");

    err = CncAddProfile(myConNameP, 'u328', 57600, 0, 0,
        "AT&FX4", 0, true, false);

    MemPtrFree(myConNameP);
}
```

## CncDefineParamID

**Purpose** Macro that creates and returns a parameter ID.

**Declared In** ConnectionMgr.h

**Prototype** CncDefineParamID (parameterRange, parameterType, parameterID)

**Parameters** -> parameterRange  
Use kCncParamThirdPartiesRange to specify that this parameter is not defined by the OS.

## Connection Manager

### Connection Manager Functions

---

-> parameterType

The type of value stored for the parameter. See [“Profile Parameter Types”](#) for a list of possible values.

-> parameterID

A unique value between 0 to 1023. The value must be unique within the profile for which you are defining the parameter.

If you are using a parameterType of kCncParamSystemFlag, specify a value from 0 to 31 to identify which of the system flag bit is to be set.

**Result** Returns the parameter ID as a UInt16 value.

**Comments** You use this macro only if you are defining your own connection profile and have a parameter that you need to define within that profile. The parameter ID immediately precedes its parameter value in the Connection Manager profile database. Because of how the database is formatted, the parameter ID must tell the Connection Manager how to interpret the next series of bytes. For this reason, the high order bits of the parameter ID include information about the type of value and whether the value is defined by the system or a third party.

**Compatibility** Parameter IDs of this format are only used if [4.0 New Feature Set](#) is present.

**See Also** [CncProfileSettingSet](#), [CncProfileSettingGet](#)

## CncDeleteProfile

|                      |                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Removes a profile from the Connection Manager.                                                                                                                                                                                                                               |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                                                                                                                                                                              |
| <b>Prototype</b>     | <code>Err CncDeleteProfile (const Char *name)</code>                                                                                                                                                                                                                         |
| <b>Parameters</b>    | -> name                    Pointer to the name of the profile to be deleted.                                                                                                                                                                                                 |
| <b>Result</b>        | <code>errNone</code> No error.<br><code>cncErrProfileReadOnly</code> The profile could not be deleted because it is read only.<br><code>cncErrProfileNotFound</code> The profile could not be found.<br><code>cncErrConDBNotFound</code> The connection database is missing. |
| <b>Comments</b>      | The profiles that come preinstalled on the unit are read only and cannot be deleted.                                                                                                                                                                                         |
| <b>Compatibility</b> | Implemented only if <a href="#">New Serial Manager Feature Set</a> is present.<br>If <a href="#">Connection Manager Feature Set</a> is present, use <a href="#">CncProfileDelete</a> instead of using this function.                                                         |

## **CncGetParamType**

- Purpose** Macro that returns the parameter type portion of the parameter ID.
- Declared In** `ConnectionMgr.h`
- Prototype** `CncGetParamType (parameterID)`
- Parameters** `-> parameterID` A `UInt16` that contains the parameter ID.
- Result** Returns a `UInt16` value where bits 11 through 14 contain one of the values in "[Profile Parameter Types](#)" and the other bits are clear.
- Compatibility** Parameter IDs of this format are only used if [4.0 New Feature Set](#) is present.
- See Also** [CncProfileSettingSet](#), [CncProfileSettingGet](#)

## **CncGetProfileInfo**

- Purpose** Returns the settings for a profile.
- Declared In** `ConnectionMgr.h`
- Prototype** `Err CncGetProfileInfo (Char *name, UInt32 *port, UInt32 *baud, UInt16 *volume, UInt16 *handShake, Char *initString, Char *resetString, Boolean *isModem, Boolean * isPulse)`
- Parameters**
- |                         |                                                                                                                                                                            |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; name</code> | Pointer to the name of the profile to be returned. Passing in NULL causes this function to return the settings for the profile currently selected in the Connection panel. |
| <code>&lt;- port</code> | Pointer to the port identifier that the profile uses.                                                                                                                      |
| <code>&lt;- baud</code> | Pointer to the baud rate that has been set for this profile.                                                                                                               |

|                                |                                                                                                                                                                  |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- volume</code>      | Pointer to the volume of the device (applies only to modems).                                                                                                    |
| <code>&lt;- handShake</code>   | Pointer to the flow control setting (hardware handshaking). 0 indicates automatic (on at speeds > 2400 baud), 1 indicates always on, and 2 indicates always off. |
| <code>&lt;- initString</code>  | Pointer to the initialization string for the device (applies only to modems).                                                                                    |
| <code>&lt;- resetString</code> | Pointer to the reset string for the device (applies only to modems).                                                                                             |
| <code>&lt;- isModem</code>     | Pointer to a Boolean value: <code>true</code> for Modem, <code>false</code> for Direct.                                                                          |
| <code>&lt;- isPulse</code>     | Pointer to a Boolean value: <code>true</code> for Pulse dial, <code>false</code> for TouchTone.                                                                  |

|               |                                     |                                                                        |
|---------------|-------------------------------------|------------------------------------------------------------------------|
| <b>Result</b> | <code>errNone</code>                | No error.                                                              |
|               | <code>cncErrGetProfileFailed</code> | The get profile operation failed. The profile may or may not be there. |
|               | <code>cncErrProfileNotFound</code>  | The profile could not be found                                         |
|               | <code>cncErrConDBNotFound</code>    | The connection database is missing.                                    |

**Comments** One or more of the parameters may be set to `NULL` if that information is not desired.

**Compatibility** Implemented only if [New Serial Manager Feature Set](#) is present. If [Connection Manager Feature Set](#) is present, use [CncProfileSettingGet](#) with one of the "[Profile Parameter Constants](#)" instead of using this function.

**Example**

```
{
    UInt32 portID, baud;
    UInt16 openPort;
    // get port id
    err = CncGetProfileInfo("Direct Serial", &portID, &baud,
```

## Connection Manager

### Connection Manager Functions

---

```
        0, 0, 0, 0, 0, 0);
    if(!err)
    { // open the port
        SrmOpen(portID, baud, &openPort);
    }
}
```

## CncGetProfileList

**Purpose** Returns a list of available profiles that are available through the Connection Manager.

**Declared In** ConnectionMgr.h

**Prototype** Err CncGetProfileList (Char \*\*\*nameListPPP,  
UInt16 \*countP)

**Parameters** <- nameListPPP Pointer to a pointer to a list of profile names.  
<- countP Pointer to the number of profile names.

## Connection Manager

### Connection Manager Functions

---

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Result</b>        | <code>errNone</code> No error.<br><code>cncErrGetProfileListFailed</code><br>The profile list could not be found.<br><code>cncErrConDBNotFound</code><br>The connection database is missing.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Comments</b>      | Allocation of the list is handled by the Connection Manager; deallocation is the responsibility of the calling application. Appended to the end of the list will be “-Current-”, which represents the profile currently selected in the Connection panel.                                                                                                                                                                                                                                                                                                                                   |
| <b>Compatibility</b> | Implemented only if <a href="#">New Serial Manager Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Example</b>       | <pre>//Declared globally Char ** globalProfileList; ListType *listP; UInt16 globalProfileCount;  void SetConnectionList () {     //Get the list from the Connection Manager     err = CncGetProfileList (&amp;globalProfileList,         &amp;globalProfileCount);     //Set the UI list     LstSetListChoices(listP, globalProfileList,         globalProfileCount); }  void StopApplication() {     UInt16 i;      //Deallocate the connection list     For(i = 0; i &lt; globalProfileCount; i++)         MemPtrFree(globalProfileList[ i ]);     MemPtrFree(globalProfileList); }</pre> |

## CncGetSystemFlagBitnum

|                      |                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that returns the number uniquely identifying a system flag parameter.                              |
| <b>Declared In</b>   | <code>ConnectionMgr.h</code>                                                                             |
| <b>Prototype</b>     | <code>CncGetSystemFlagBitnum (parameterID)</code>                                                        |
| <b>Parameters</b>    | -> <code>parameterID</code> The <code>UInt16</code> containing the parameter ID.                         |
| <b>Result</b>        | Returns the ID of the system flag parameter, which is a value from 0 to 31.                              |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present. |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet</a> , <a href="#">CncProfileSettingGet</a>                              |

## CncGetTrueParamID

|                      |                                                                                                                                                     |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that returns the portion of the parameter ID that uniquely identifies the parameter.                                                          |
| <b>Declared In</b>   | <code>ConnectionMgr.h</code>                                                                                                                        |
| <b>Prototype</b>     | <code>CncGetTrueParamID (parameterID)</code>                                                                                                        |
| <b>Parameters</b>    | -> <code>parameterID</code> A <code>UInt16</code> containing the parameter ID.                                                                      |
| <b>Result</b>        | Returns a <code>UInt16</code> containing just the parameter ID. The high-order bits, which specify the parameter type and address space, are clear. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                                            |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet</a> , <a href="#">CncProfileSettingGet</a>                                                                         |

## **CncIsFixedLengthParamType**

- Purpose** Macro that specifies whether the parameter value is fixed length or variable length.
- Declared In** `ConnectionMgr.h`
- Prototype** `CncIsFixedLengthParamType (parameterID)`
- Parameters** `-> parameterID` A `UInt16` containing the parameter ID.
- Result** Returns `true` if the parameter is a fixed length parameter type such as `UInt32`, or `false` if it is a variable length type.
- Compatibility** Parameter IDs of this format are only used if [Connection Manager Feature Set](#) is present.
- See Also** [CncProfileSettingSet](#), [CncProfileSettingGet](#)

## **CncIsSystemFlags**

- Purpose** Macro that returns whether the parameter value is a system flag.
- Declared In** `ConnectionMgr.h`
- Prototype** `CncIsSystemFlags (parameterID)`
- Parameters** `-> parameterID` The `UInt16` containing the parameter ID.
- Result** Returns `true` if the parameter type is a system flag. Returns `false` otherwise.
- Compatibility** Parameter IDs of this format are only used if [Connection Manager Feature Set](#) is present.
- See Also** [CncProfileSettingSet](#), [CncProfileSettingGet](#)

## CncIsSystemRange

|                      |                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that specifies whether the parameter is in the system range or in the third-party range.                                |
| <b>Declared In</b>   | <code>ConnectionMgr.h</code>                                                                                                  |
| <b>Prototype</b>     | <code>CncIsSystemRange (parameterID)</code>                                                                                   |
| <b>Parameters</b>    | -> <code>parameterID</code> A <code>UInt16</code> containing the parameter ID.                                                |
| <b>Result</b>        | Returns <code>true</code> if the parameter ID is defined by Palm OS, or <code>false</code> if it is defined by a third party. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                      |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet</a> , <a href="#">CncProfileSettingGet</a>                                                   |

## CncIsThirdPartiesRange

|                      |                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that specifies whether the parameter is defined by a third party.                                                   |
| <b>Declared In</b>   | <code>ConnectionMgr.h</code>                                                                                              |
| <b>Prototype</b>     | <code>CncIsThirdPartiesRange (parameterID)</code>                                                                         |
| <b>Parameters</b>    | -> <code>parameterID</code> A <code>UInt16</code> containing the parameter ID.                                            |
| <b>Result</b>        | Returns <code>true</code> if the parameter is a third-party parameter, or <code>false</code> if it is a system parameter. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                  |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet</a> , <a href="#">CncProfileSettingGet</a>                                               |

## **CncIsVariableLengthParamType**

|                      |                                                                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that returns whether the parameter value is a variable-length type.                                                                                    |
| <b>Declared In</b>   | <code>ConnectionMgr.h</code>                                                                                                                                 |
| <b>Prototype</b>     | <code>CncIsVariableLengthParamType (parameterID)</code>                                                                                                      |
| <b>Parameters</b>    | <code>-&gt;parameterID</code> A <code>UInt16</code> containing the parameter ID.                                                                             |
| <b>Result</b>        | Returns <code>true</code> if the parameter is a variable-length string or a buffer or <code>false</code> if it holds a fixed-length type such as an integer. |
| <b>Compatibility</b> | Parameter IDs of this format are only used if <a href="#">Connection Manager Feature Set</a> is present.                                                     |
| <b>See Also</b>      | <a href="#">CncProfileSettingSet</a> , <a href="#">CncProfileSettingGet</a>                                                                                  |

## **CncProfileCloseDB**

|                    |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Closes the Connection Manager profile database.                                                                                                                                                               |
| <b>Declared In</b> | <code>ConnectionMgr.h</code>                                                                                                                                                                                  |
| <b>Prototype</b>   | <code>Err CncProfileCloseDB (void)</code>                                                                                                                                                                     |
| <b>Parameters</b>  | None.                                                                                                                                                                                                         |
| <b>Result</b>      | <code>errNone</code> No error.<br><code>kCncErrDBAccessFailed</code> The database could not be closed or this is a reference counting error.                                                                  |
| <b>Comments</b>    | Use <a href="#">CncProfileOpenDB</a> and <code>CncProfileCloseDB</code> as an optimization if you make several Connection Manager calls in succession. All Connection Manager calls open the profile database |

when they begin and close the database when they are finished. The Connection Manager maintains a reference count that tells it whether the database is open. If you call `CncProfileOpenDB` before making another Connection Manager call, the next call does not open or close the database. This saves your application the overhead of opening and closing the database each time a call is made.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

## CncProfileCount

**Purpose** Returns the number of connection profiles currently defined in the Connection Manager profile database.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncProfileCount (UInt16 *profilesCountP)`

**Parameters** `<- profilesCountP`  
The number of profiles.

**Result** `errNone` No error.  
`kCncErrDBAccessFailed`  
The profile database could not be opened.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncGetProfileList](#)

## **CncProfileCreate**

|                      |                                                                                                                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Adds a profile record to the Connection Manager profile database.                                                                                                                                                                                                                                         |
| <b>Declared In</b>   | ConnectionMgr.h                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>     | Err CncProfileCreate (CncProfileID *profileIdP)                                                                                                                                                                                                                                                           |
| <b>Parameters</b>    | <- profileIdP      Upon return, the unique ID of the new profile.                                                                                                                                                                                                                                         |
| <b>Result</b>        | errNone              No error.<br>kCncErrDBAccessFailed      The profile database could not be opened.<br>a Data Manager error      The new record could not be created.                                                                                                                                  |
| <b>Comments</b>      | This function creates a new empty record in the Connection Manager profile database. To populate the profile, use <a href="#">CncProfileSettingSet</a> to set parameter values, including the profile name. Use <a href="#">CncDefineParamID</a> if you need to store information unique to your profile. |
| <b>Compatibility</b> | Implemented only if <a href="#">Connection Manager Feature Set</a> is present.                                                                                                                                                                                                                            |
| <b>See Also</b>      | <a href="#">CncAddProfile</a> , <a href="#">CncProfileDelete</a>                                                                                                                                                                                                                                          |

## **CncProfileDelete**

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <b>Purpose</b>     | Deletes a profile.                                      |
| <b>Declared In</b> | ConnectionMgr.h                                         |
| <b>Prototype</b>   | Err CncProfileDelete (CncProfileID profileId)           |
| <b>Parameters</b>  | profileId              The ID of the profile to delete. |
| <b>Result</b>      | errNone              No error.                          |

`kCncErrDBAccessFailed`

The profile database could not be opened, or the record could not be deleted.

`kCncErrProfileParamNotFound`

The database does not contain a profile with the specified ID.

**Comments** The profiles that come preinstalled on the unit are read only and cannot be deleted.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncDeleteProfile](#), [CncProfileCreate](#)

## **CncProfileGetCurrent**

**Purpose** Returns the ID of the currently selected profile in the Connection panel.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncProfileGetCurrent  
(CncProfileID *profileIdP)`

**Parameters** `<- profileIdP` The ID of the current profile.

**Result** `errNone` No error.

`kCncErrDBAccessFailed`

The profile database could not be opened.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

## CncProfileGetIDFromName

- Purpose** Returns the profile ID given its name.
- Declared In** `ConnectionMgr.h`
- Prototype**  
`Err CncProfileGetIDFromName  
(const Char *profileNameP,  
CncProfileID *profileIdP)`
- Parameters**
- > `profileNameP` The name of the profile. The name is displayed in a pop-up list in the Connection panel. If you pass the string “-Current-”, this function returns the ID of the current profile.
  - <- `profileIdP` The profile ID.
- Result**
- `errNone` No error.
  - `kCncErrDBAccessFailed`  
The profile database could not be opened.
  - `kCncErrProfileParamNotFound`  
No profile with the specified name.
- Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.
- See Also** [CncProfileGetCurrent](#), [CncProfileGetIDFromIndex](#), [CncProfileGetIndex](#)

## CncProfileGetIndex

- Purpose** Returns the index of the profile given its ID.
- Declared In** `ConnectionMgr.h`
- Prototype**  
`Err CncProfileGetIndex (CncProfileID profileId,  
UInt16 *indexP)`
- Parameters**
- > `profileId` The profile ID.

## Connection Manager

### Connection Manager Functions

---

`<- indexP`      The index of the profile's record in the Connection Manager profile database.

**Result**      `errNone`      No error.  
`kCncErrDBAccessFailed`  
                 The profile database could not be opened.  
`kCncErrProfileParamNotFound`  
                 No profile with the specified ID.

**Compatibility**      Implemented only if [Connection Manager Feature Set](#) is present.

**See Also**      [CncProfileGetIDFromIndex](#)

## CncProfileOpenDB

**Purpose**      Opens the Connection Manager profile database.

**Declared In**      `ConnectionMgr.h`

**Prototype**      `Err CncProfileOpenDB (void)`

**Parameters**      None

**Result**      `errNone`      No error.  
`kCncErrDBAccessFailed`  
                 The profile database could not be opened.

**Comments**      Use `CncProfileOpenDB` and [CncProfileCloseDB](#) as an optimization if you make several Connection Manager calls in succession. All Connection Manager calls open the profile database when they begin and close the database when they are finished. The Connection Manager maintains a reference count that tells it whether the database is open. If you call `CncProfileOpenDB` before making another Connection Manager call, the next call does not open or close the database. This saves your application the overhead of opening and closing the database each time a call is made.

The Connection Manager profile database is created if it does not exist.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

## **CncProfileSetCurrent**

**Purpose** Sets the current profile.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncProfileSetCurrent (CncProfileID profileId)`

**Parameters** `->profileId` The ID of the profile to be made current.

**Result** `errNone` No error.  
`kCncErrDBAccessFailed`  
The profile database could not be opened.

**Comments** The current profile is the profile that is used for the next network connection attempt.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncProfileGetCurrent](#)

## CncProfileSettingGet

| -> profileId                      | The ID of the profile from which to obtain a parameter value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |              |                                                               |                       |                                                                                                                                                                                |                              |                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |
| -> paramId                        | The ID of the parameter to obtain. See " <a href="#">Profile Parameter Constants</a> " for a list of the parameters used in the profiles that come preinstalled on the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |              |                                                               |                       |                                                                                                                                                                                |                              |                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |
| <- paramBufferP                   | A pointer to a buffer into which to write the parameter value. If the parameter stores a variable-sized value, you can determine the necessary size by passing NULL for paramBufferP. Upon return, paramSize contains the required size.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                                                               |                       |                                                                                                                                                                                |                              |                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |
| <-> ioParamSizeP                  | On input, a pointer to the size of the buffer into which to write the parameter. On output, points to the number of bytes written to paramBufferP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |                                                               |                       |                                                                                                                                                                                |                              |                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |

| kCncErrProfileBadSystemFlagBitnum | An attempt was made to obtain the value of a system flag that is undefined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                                               |                       |                                                                                                                                                                                |                              |                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |

`kCncErrProfileBadParamSize`

The `paramBufferP` buffer is too small.  
`ioParamSizeP` contains the correct size for the buffer.

`kCncErrProfileParamNotFound`

The specified parameter is not defined in the profile.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncProfileSettingSet](#), [CncGetProfileInfo](#)

## CncProfileSettingSet

**Purpose** Sets a parameter value in the specified profile.

**Declared In** `ConnectionMgr.h`

**Prototype** `Err CncProfileSettingSet (CncProfileID iProfileId, UInt16 paramId, const void *paramBufferP, UInt16 paramSize)`

**Parameters**

- > `iProfileId` The ID of the profile.
- > `paramId` The ID of the parameter. See "[Profile Parameter Constants](#)" for a list of the parameters defined in the preinstalled connection profiles.
- > `paramBufferP` A pointer to the value to set for this parameter.
- > `paramSize` The size of the buffer passed in `paramBufferP`. See "[Profile Parameter Size Constants](#)."

**Result** `errNone` No error.

`kCncErrDBAccessFailed`  
The profile database could not be opened.

## Connection Manager

### Connection Manager Functions

---

`kCncErrProfileParamNotFound`

No profile with the specified ID.

`kCncErrProfileSetParamFailed`

The Connection Manager failed to set the value of the parameter.

`kCncErrProfileBadParamSize`

The `paramBufferP` buffer is too small. Most likely, the passed in size does not allow space for a string parameter's null terminator.

`kCncErrProfileParamNameHasChange`

An attempt was made to set the profile name to a name that is already used. The Connection Manager appends a duplication number to the end of the name and returns this error. You should use [CncProfileSettingGet](#) to find out the new name.

**Compatibility** Implemented only if [Connection Manager Feature Set](#) is present.

**See Also** [CncDefineParamID](#), [CncProfileSettingGet](#)

# Exchange Manager

---

This chapter describes the Exchange Manager API declared in the header file `ExgMgr.h` and the Exchange Local Library API declared in the header file `ExgLocalLib.h`. It discusses the following topics:

- [Exchange Manager Data Structures](#)
- [Exchange Manager Constants](#)
- [Exchange Manager Functions](#)
- [Application-Defined Functions](#)

For more information on the Exchange Manager, see the chapter “[Object Exchange](#)” on page 1 of *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Exchange Manager Data Structures

### ExgAskResultType

The `ExgAskResultType` enum defines possible values for the `result` field of the [sysAppLaunchCmdExgAskUser](#) launch code parameter block.

```
typedef enum {
    exgAskDialog,
    exgAskOk,
    exgAskCancel }
ExgAskResultType;
```

### Value Descriptions

|                           |                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>exgAskDialog</code> | The Exchange Manager should display a dialog that prompts the user to confirm the receipt of data. See <a href="#">ExgDoDialog</a> . |
| <code>exgAskOk</code>     | Accept the data.                                                                                                                     |
| <code>exgAskCancel</code> | Reject the data.                                                                                                                     |

### ExgGoToType

The `ExgGoToType` structure defines the `goToParams` field of the [ExgSocketType](#) structure. Applications that want to be launched after the data is received place their creator IDs in the `goToCreator` field and define the `goToParams` field. The values in this structure are copied to the [sysAppLaunchCmdGoto](#) launch code's parameter block.

```
typedef struct {
    UInt16 dbCardNo;
    LocalID dbID;
    UInt16 recordNum;
    UInt32 uniqueID;
    UInt32 matchCustom;
} ExgGoToType;
```

### Field Descriptions

|                          |                                                                     |
|--------------------------|---------------------------------------------------------------------|
| <code>dbCardNo</code>    | The card number of the database that contains the added record.     |
| <code>dbID</code>        | The local ID of the database that contains the added record.        |
| <code>recordNum</code>   | The index of the record that was added.                             |
| <code>uniqueID</code>    | The unique ID of the record that was added. This field is not used. |
| <code>matchCustom</code> | Application-specific information.                                   |

## ExgLocalSocketInfoType

The `ExgLocalSocketInfoType` structure identifies information specific to the Local Exchange Library. The `socketRef` field of the [ExgSocketType](#) structure is set to this structure when you send and receive data using the Local Exchange Library. The Local Exchange Library creates this structure if it does not already exist. You only need to create it if you want to supply non-default values for the `noAsk` or `previewInfoP` fields.

```
typedef struct {
    Boolean freeOnDisconnect;
    Boolean noAsk;
    ExgPreviewInfoType *previewInfoP;
    FileHand tempFileH;
    Err err;
    ExgLocalOpType op;
} ExgLocalSocketInfoType;
```

### Field Descriptions

- |                               |                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>freeOnDisconnect</code> | Whether the structure is freed when the <a href="#">ExgDisconnect</a> call is made. The default is <code>true</code> . In general, code that allocates a structure should be responsible for freeing that structure. Therefore, if you have allocated <code>ExgLocalSocketInfoType</code> , you should set this field to <code>false</code> and explicitly free the structure when you are finished with it. |
| <code>noAsk</code>            | Set to <code>true</code> to disable the display of the exchange dialog. If you want to, for example, create a <code>vCalendar</code> object and send it to the Datebook application in response to a user command, you probably want to set <code>noAsk</code> to <code>true</code> so that the user does not have to confirm the receipt of the data they just requested you to send.                       |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>previewInfoP</code> | A pointer to an <a href="#">ExgPreviewInfoType</a> structure, used to display a preview of the data. If you wanted to simply use another application to help display data, you would create and initialize this structure.                                                                                                                                                                                                                                                                    |
| <code>tempFileH</code>    | A temporary buffer that the Local Exchange Library uses. Do not set this field directly; the Local Exchange Library should set it.                                                                                                                                                                                                                                                                                                                                                            |
| <code>err</code>          | The error code returned from the Local Exchange Library. Do not set this field directly; the Local Exchange Library should set it.                                                                                                                                                                                                                                                                                                                                                            |
| <code>op</code>           | The operation in progress. Do not set this field directly. The Local Exchange Library sets this field to one of the following:<br><br><code>exgLocalOpNone</code> No operation in progress.<br><code>exgLocalOpPut</code> A send is in progress.<br><code>exgLocalOpAccept</code> A receive is in progress.<br><code>exgLocalOpGet</code> A get is in progress.<br><code>exgLocalOpGetSender</code> The library is receiving information from the sending application during a get operation. |

## ExgPreviewInfoType

The ExgPreviewInfoType structure provides information to the [ExgNotifyPreview](#) function. The ExgNotifyPreview function uses this information to have the application display a preview of the data to be received in the exchange dialog.

```
typedef struct {
    UInt16          version;
    ExgSocketType  *socketP;
    UInt16          op;
    Char           *string;
    UInt32          size;
    RectangleType  bounds;
    UInt16          types;
    Err            error;
} ExgPreviewInfoType;
```

### Field Descriptions

- > version    Set this field to 0 to specify version 0 of this structure.
  
- > socketP    A pointer to the socket structure (see [ExgSocketType](#)). The libraryRef field must identify the exchange library from which preview data should be received, and the target, type, or name field should be defined as well.
  
- > op         One of the following constants:
  - exgPreviewDialog         Display a modal dialog containing the preview. This constant is only used in situations where one application launches another to display data.
  
  - exgPreviewDraw            The preview is a graphic.
  
  - exgPreviewLongString     The preview is a long string.

|                           |                                    |                                                                                                                                                                                                                                                  |
|---------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | <code>exgPreviewQuery</code>       | Ask the application which preview operations it supports. The answer is returned in the <code>types</code> field. If the application does not support any preview modes, the <code>error</code> field contains <code>exgErrNotSupported</code> . |
|                           | <code>exgPreviewShortString</code> | The preview is a short string.                                                                                                                                                                                                                   |
| <code>&lt;- string</code> |                                    | A buffer into which the application places the string preview if <code>exgPreviewLongString</code> or <code>exgPreviewShortString</code> is specified.                                                                                           |
| <code>-&gt; size</code>   |                                    | The allocated size of the <code>string</code> field.                                                                                                                                                                                             |
| <code>-&gt; bounds</code> |                                    | The bounds of the rectangle in which the application draws the graphic if <code>exgPreviewDraw</code> is specified.                                                                                                                              |
| <code>&lt;- types</code>  |                                    | Upon return from an <code>exgPreviewQuery</code> operation, a bit field identifying the types of previews the application supports.                                                                                                              |
| <code>&lt;- error</code>  |                                    | The error code returned from the application. If <code>errNone</code> , the preview operation was successful.                                                                                                                                    |

Applications can define and use their own constants for the preview operation. Operations specific to an application are numbered starting at `exgPreviewFirstUser` and should be no greater than `exgPreviewLastUser`.

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## ExgSocketType

The ExgSocketType structure defines an Exchange Manager socket, which is passed to most Exchange Manager functions. The ExgSocketPtr type points to a ExgSocketType structure.

```
typedef struct ExgSocketType {
    UInt16 libraryRef;
    UInt32 socketRef;
    UInt32 target;
    UInt32 count;
    UInt32 length;
    UInt32 time;
    UInt32 appData;
    UInt32 goToCreator;
    ExgGoToType goToParams;
    UInt16 localMode:1;
    UInt16 packetMode:1;
    UInt16 noGoTo:1;
    UInt16 noStatus:1;
    UInt16 preview:1;
    UInt16 reserved:11;
    Char *description;
    Char *type;
    Char *name;
} ExgSocketType;
```

```
typedef ExgSocketType* ExgSocketPtr;
```

Note that when data is received, some of the fields in this structure may not have values. When you are sending data, it is recommended that you provide values for all of these fields, but you should not rely on receiving values for the fields marked optional.

### Field Descriptions

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>libraryRef</code>  | <p>The exchange library in use. When an application or library receives a socket, this field is already assigned.</p> <p>When sending data, applications may identify the exchange library they want to connect with by providing a URL in the <code>name</code> field. If so, they should use 0 for the <code>libraryRef</code> field. The Exchange Manager then determines which library corresponds to the URL and assigns the <code>libraryRef</code> field. See the Comments in the <a href="#">ExgPut</a> function description for more information.</p> |
| <code>socketRef</code>   | <p>The connection identifier. This value is supplied by the exchange library when a connection is established. It contains any necessary library-specific data.</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>target</code>      | <p>The creator ID of the application that should receive the message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>count</code>       | <p>The number of objects in this connection, usually 1 (optional).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>length</code>      | <p>The total byte count for all objects being sent (optional).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>time</code>        | <p>The last modified time of object (optional).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>appData</code>     | <p>Application-specific information (optional).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>goToCreator</code> | <p>The creator ID of the application to launch using the <a href="#">sysAppLaunchCmdGoto</a> launch code after the item is received if <code>noGoTo</code> is 0. The value is assigned by the application that receives the object. See the Comments section in <a href="#">ExgDisconnect</a> for more information.</p>                                                                                                                                                                                                                                        |
| <code>goToParams</code>  | <p>If <code>goToCreator</code> is specified, then this field contains data that is copied into the launch code's parameter block. See <a href="#">ExgGoToType</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                         |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>localMode</code>   | Set to 1 to exchange with local device only. A <code>localMode</code> of 1 is equivalent to specifying a URL with the <code>exgLocalPrefix</code> . Set to 0 to enable an exchange with a remote machine. The default is 0.                                                                                                                                                                                                                              |
| <code>packetMode</code>  | Set to 1 to use connectionless packet mode (Ultra). The default is 0. Ultra mode is not currently supported.                                                                                                                                                                                                                                                                                                                                             |
| <code>noGoTo</code>      | Set to 1 to disable launching the application with <a href="#"><code>sysAppLaunchCmdGoto</code></a> . The default is 0.                                                                                                                                                                                                                                                                                                                                  |
| <code>noStatus</code>    | <p>If <code>true</code>, the exchange library should not display a progress dialog. If <code>false</code>, the library can display a progress dialog. The default is <code>false</code>.</p> <p>The Exchange Manager sets and clears this bit at various times while data is received. Applications may also want to set this bit if they use the Local Exchange Library and want to prevent the progress dialog from being displayed during a send.</p> |
| <code>preview</code>     | If <code>true</code> , a preview is in progress. The <a href="#"><code>ExgNotifyPreview</code></a> function sets this bit while the preview takes place and clears it when the preview is finished. Exchange libraries should not discard any data while a preview is in progress because the full data must be sent later if the receiving user accepts it.                                                                                             |
| <code>reserved</code>    | Reserved system flags.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>description</code> | A pointer to the text description of the object (optional).                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>type</code>        | A pointer to the MIME type of the object (optional).                                                                                                                                                                                                                                                                                                                                                                                                     |

## Exchange Manager

### Exchange Manager Constants

---

name                      The name of the object being sent. This can be a URL whose scheme identifies the exchange library to connect with.

If the name has a colon, it is treated as a URL.

**Compatibility**        The noGoTo and noStatus flags are only defined if [3.5 New Feature Set](#) is present, and the noStatus flag has no effect unless [4.0 New Feature Set](#) is present. The preview flag is only defined if [4.0 New Feature Set](#) is present.

## Exchange Manager Constants

### Registry ID Constants

The registry ID constants are used in the Exchange Manager registry. Exchange libraries register for the URL prefixes they handle, and applications register for the types of data they receive. The registry ID constants specify which type of data is being registered for.

| <b>Constant</b>                | <b>Value</b>         | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exgRegCreatorID</code>   | <code>0xffffb</code> | Register for a creator ID. The <code>target</code> field of the <a href="#">ExgSocketType</a> contains the creator ID of the application that should receive the data. Typically, the application with the matching creator ID receives the data, but it is possible for one application to register for another's creator ID and receive data in its place.                                                                                    |
| <code>exgRegSchemeID</code>    | <code>0xffffc</code> | Register for a URL scheme. Typically, only exchange libraries register for URL schemes. Applications can register for URL schemes, but they only receive the URL when <a href="#">ExgRequest</a> is called. If the <code>name</code> field of the <code>ExgSocketType</code> contains a colon (:), the portion of the URL before the colon is the URL scheme. The default library registered for URLs with that scheme will handle the message. |
| <code>exgRegExtensionID</code> | <code>0xffffd</code> | Register for a filename extension. If the <code>name</code> field of the <code>ExgSocketType</code> contains a period (.), the portion of the name after the last period is the filename extension. The application registered to handle files of that extension will handle the message.                                                                                                                                                       |
| <code>exgRegTypeID</code>      | <code>0xffffe</code> | Register for a MIME type. If the <code>type</code> field of the <code>ExgSocketType</code> contains a value, the application registered to receive that MIME type handles the message.                                                                                                                                                                                                                                                          |

**Compatibility** The `exgRegCreatorID` and `exgRegSchemeID` constants are only defined if [4.0 New Feature Set](#) is present.

## Predefined URL Schemes

The Exchange Manager provides these predefined URL schemes, for which exchange libraries can register.

## Exchange Manager

### Exchange Manager Constants

---

| Constant       | Value    | Description                                                                                                                                                                                                    |
|----------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exgBeamScheme  | "_beam"  | The URL scheme for Beam commands. By default, the IR Library handles this scheme.                                                                                                                              |
| exgSendScheme  | "_send"  | The URL scheme for Send commands. The purpose of the Send command is to provide a choice of transport mechanisms to the user; therefore, any exchange library that sends data should register for this scheme. |
| exgLocalScheme | "_local" | The URL scheme for the Local Exchange Library.                                                                                                                                                                 |

---

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

### Predefined URL Prefixes

The Exchange Manager provides the following prefixes, which can be used to construct URLs appropriate for the name field of the [ExgSocketType](#) structure. When sending data, applications provide a URL to identify the exchange library that should transport the data.

| Constant      | Value                   | Description                                                                                                                                                                                                                                          |
|---------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exgBeamPrefix | (exgBeamScheme ":")     | The URL to beam data.                                                                                                                                                                                                                                |
| exgSendPrefix | ("?" exgSendScheme ":") | A URL for the general Send command. Because this URL begins with a question mark (?), the Exchange Manager displays a dialog with a list of exchange libraries registered for the exgSendScheme. The user then chooses the desired exchange library. |

| Constant                       | Value                                                      | Description                                                                                                                                                                                           |
|--------------------------------|------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>exgSendBeamPrefix</code> | <code>("?" exgSendScheme ";"<br/>exgBeamScheme ":")</code> | A URL for the general Send command. The Exchange Manager displays a dialog with a list of exchange libraries registered for either the <code>exgSendScheme</code> or the <code>exgBeamScheme</code> . |
| <code>exgLocalPrefix</code>    | <code>(exgLocalScheme ":")</code>                          | The URL for using the Local Exchange Library.                                                                                                                                                         |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## Exchange Manager Functions

### ExgAccept

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                 |                      |         |                               |                                        |                                 |                                                                                                                       |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|---------|-------------------------------|----------------------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                  | Accepts a connection from a remote device.                                                                                                                                                                                                                                                                                                                                                      |                      |         |                               |                                        |                                 |                                                                                                                       |

| <code>exgErrNotSupported</code> | A preview is in progress, and the exchange library identified by <code>libraryRef</code> doesn't support preview mode                                                                                                                                                                                                                                                                           |                      |         |                               |                                        |                                 |                                                                                                                       |

Other error codes depend on the exchange library.

Displays a fatal error message if `socketP` does not have a `libraryRef` specified.

**Comments** Applications call this function when launched with the [sysAppLaunchCmdExgReceiveData](#) or [sysAppLaunchCmdExgPreview](#) launch code. The launch code contains `socketP` in its parameter block. Applications should pass this socket to `ExgAccept` to accept the connection, then call [ExgReceive](#) one or more times to receive the data, and then call [ExgDisconnect](#) to disconnect.

---

**NOTE:** Don't create the socket on the receiving side of an exchange. The socket is passed to you in the command parameter block of the [sysAppLaunchCmdExgReceiveData](#) or [sysAppLaunchCmdExgPreview](#) launch code.

---

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present. Preview mode is supported only if [4.0 New Feature Set](#) is present.

**See Also** [ExgConnect](#), [ExgPut](#), [ExgGet](#)

## ExgConnect

**Purpose** Establishes a connection with a remote socket.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgConnect (ExgSocketType *socketP)`

**Parameters** `-> socketP` A pointer to the socket structure (see [ExgSocketType](#)). Specify either a value for the `libraryRef` field or a URL in the `name` field. `libraryRef` should be 0 if the `name` field contains a URL.

**Result** Returns one of the following error codes:

|                                   |                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------|
| <code>errNone</code>              | Success                                                                     |
| <code>exgErrBadLibrary</code>     | Couldn't find exchange library                                              |
| <code>exgErrNotSupported</code>   | The library doesn't support the operation specified in <code>socketP</code> |
| <code>exgErrUserCancel</code>     | The user cancelled the connection operation                                 |
| <code>exgMemError</code>          | There isn't enough free memory to respond to the request                    |
| <code>exgErrNotEnoughPower</code> | The battery does not have enough power to perform the operation             |

Other error codes depend on the exchange library.

**Comments** Applications can call this function to initiate a connection for sending multiple objects or for performing two-way communications. Some exchange libraries support sending multiple objects but do not support this call. See "[Sending Multiple Objects](#)" on page 17 of *Palm OS Programmer's Companion*, vol. II, *Communications* for more information.

Before calling this function, the application must initialize the `socketP` parameter. The socket should identify the exchange library to connect with by providing either a library reference number in the `libraryRef` field or a URL in the `name` field. The default exchange library registered for that type of URL handles the connection.

To provide users with a choice of transport mechanisms, specify a URL that begins with a question mark (?). The Exchange Manager displays a dialog with a list of all exchange libraries that respond to URLs of the specified type. If only one exchange library is registered for this URL scheme, no dialog is displayed.

For example, many applications on Palm OS® 4.0 or higher support a Send command. This command generates a URL with the prefix `exgSendPrefix` (see [Predefined URL Prefixes](#)). The Exchange Manager displays a dialog containing a list of libraries registered for that URL scheme. The user selects an exchange library, and that library's `ExgLibConnect` function is called.

## Exchange Manager

### *Exchange Manager Functions*

---

If the library is not specified by either URL or library reference number (in the `libraryRef` field), the Exchange Manager by default uses the IR Library; however, if the `localMode` flag is set, the Local Exchange Library is used instead.

In addition to specifying the library, you can set the `count` field in `socketP` before making this call to indicate the number of objects that are going to be sent. Use a count of 0 if the number of objects isn't known in advance.

If no error is returned from `ExgConnect`, applications can follow this call either by sending multiple objects or requesting data from the remote device or both. To send an object, call [ExgPut](#) at the beginning of each object and call [ExgSend](#) one or more times per object to send the data. To request data from the remote device, use [ExgGet](#) (and then use [ExgReceive](#) to receive the requested data). You can use these calls in combination with each other to support two-way communications. After all of the objects have been sent and received, call [ExgDisconnect](#) to disconnect.

---

**IMPORTANT:** Not all exchange libraries support the sending of multiple objects or using `ExgGet` to request data.

---

#### **Compatibility**

Implemented only if [3.0 New Feature Set](#) is present. `ExgConnect` was for system use only until the release of Palm OS 4.0. Multiple object sending and identifying exchange libraries by URL are supported only if [4.0 New Feature Set](#) is present. On earlier releases, this function is an alias for the `ExgPut` function.

## Exchange Manager

### Exchange Manager Functions

---

**Comments** The Exchange Manager uses this function to request information from the exchange library. Applications may also call this function. The Exchange Manager defines and uses a set of operation constants that it might send to any exchange library. These constants begin with the prefix `exgLibCtlGet`. The type of the variable pointed to by `valueP` depends on the type of operation to be performed. [Table 57.1](#) lists and describes the predefined Exchange Manager operations.

**Table 57.1 ExgControl operations for all exchange libraries**

| Operation<br><code>exgLibCtlGet...</code> | value Data Type                                                           | Description                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Preview                                   | Boolean. Output only.                                                     | Returns <code>true</code> if the exchange library supports preview mode or <code>false</code> if not. If the exchange library does not respond to this operation, it is assumed to support preview mode.                                                                                                      |
| Title                                     | String buffer of size <code>exgTitleBufferSize</code> bytes. Output only. | Returns the name of the exchange library as it should appear in the Send dialog. All exchange libraries must respond to this operation.                                                                                                                                                                       |
| Version                                   | UInt16. Output only.                                                      | Returns the version of the exchange library API that this library implements. The constant <code>exgLibAPIVersion</code> defines the current version number. If the exchange library does not respond to this operation, the library supports the version of the Exchange Library API defined in Palm OS 4.0. |

An exchange library may also define its own operations. For example, the IR Library supports operations to enable or disable beaming, to set the baud rates, or to use the serial port (see “[IR Control Constants](#)” on page 1378). The SMS Library supports operations that allow you to set the SMS preferences for sending messages or to manipulate multipart messages (see “[SMS Control](#)”).

[Constants](#)” on page 2232). Operations specific to an exchange library are numbered starting at `exgLibCtlSpecificOp`.

The `socketP` passed to this function must identify an exchange library either using the `libraryRef` field or using a URL in the `name` field. The Comments section in [ExgConnect](#) describes how an application should identify the exchange library.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## ExgDBRead

**Purpose**    Converts a Palm OS database from its internal format and writes it to storage RAM.

**Declared In**    `ExgMgr.h`

**Prototype**    `Err ExgDBRead (ExgDBReadProcPtr readProcP,  
ExgDBDeleteProcPtr deleteProcP, void* userDataP,  
LocalID* dbIDP, UInt16 cardNo,  
Boolean* needResetP, Boolean keepDates)`

**Parameters**

|                                |                                                                                                                                                                                                                                                 |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; readProcP</code>   | A pointer to a function that reads in the database and passes it to <code>ExgDBRead</code> . See <a href="#">ExgDBReadProcPtr</a> for details.                                                                                                  |
| <code>-&gt; deleteProcP</code> | A pointer to a function that is called if a database with an identical name already exists on the device. See <a href="#">ExgDBDeleteProcPtr</a> for details.                                                                                   |
| <code>-&gt; userDataP</code>   | A pointer to any data you want to pass to either the <code>readProcP</code> or <code>deleteProcP</code> functions. Often, this parameter is used to pass the <a href="#">ExgSocketType</a> that is required by many Exchange Manager functions. |
| <code>&lt;- dbIDP</code>       | The ID of the database that <code>ExgDBRead</code> created on the local device.                                                                                                                                                                 |
| <code>&lt;- cardNo</code>      | The number of the card on which the database was stored by <code>ExgDBRead</code> .                                                                                                                                                             |

## Exchange Manager

### Exchange Manager Functions

---

`<- needResetP` Set to `true` by `ExgDBRead` if the `dmHdrAttrResetAfterInstall` attribute bit is set in the received database.

`-> keepDates` Specify `true` to retain the creation, modification, and last backup dates as set in the received database header. Specify `false` to reset these dates to the current date.

**Result** Returns `errNone` if successful; otherwise, returns one of the data manager error codes (`dmErr. . .`) or a callback-specific error code. (If the `readProcP` function returns an error, it is also returned by `ExgDBRead`.)

**Comments** This function converts data received from an exchange library or from any other transport mechanism into a Palm OS database and stores that database in the storage heap. It is not required that you use this function in conjunction with Exchange Manager calls. That is, it's possible to use this function to perform other operations, such as converting a database created on the desktop computer to a Palm OS formatted database in the storage heap.

The primary use of this function, however, is to receive a database that has been beamed onto the device. In this case, call `ExgDBRead` in response to the launch code

[sysAppLaunchCmdExgReceiveData](#) after calling [ExgAccept](#) to accept the connection. Place the call to [ExgReceive](#) in the read callback function you passed as the `readProcP` parameter. Pass the [ExgSocketType](#) structure returned from `ExgAccept` in the `userDataP` parameter so that you have access to it in the read callback function.

The read callback function performs the actual reading of data. `ExgDBRead` calls the read callback function multiple times. Each time, the `sizeP` parameter contains the number of bytes `ExgDBRead` expects the data returned in `dataP` to contain. It's important for the read callback function to set the number of bytes (in `sizeP`) that it actually placed in `dataP` if it's not the same as what `ExgDBRead` expected. `ExgDBRead` stops calling the read callback function after 0 is returned in `sizeP`.

The callback function you pass in `deleteProcP` handles the case where the database being read already exists on the device. It is called only in that circumstance. The callback function may want to close the database if it is open, change the existing database's name, or delete the existing database to allow an overwrite. See [ExgDBDeleteProcPtr](#) for more information.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

**See Also**        [ExgDBWrite](#)

## ExgDBWrite

- Purpose** Converts a given Palm OS database from its internal format on the local device and writes it using a function you supply.
- Declared In** `ExgMgr.h`
- Prototype** `Err ExgDBWrite (ExgDBWriteProcPtr writeProcP, void* userDataP, const char* nameP, LocalID dbID, UInt16 cardNo)`
- Parameters**
- > `writeProcP` A pointer to a function that writes out the database identified by `dbID`. See [ExgDBWriteProcPtr](#) for details.
  - > `userDataP` A pointer to any data you want to pass to the `writeProcP` function. Often, this parameter is used to pass the [ExgSocketType](#) that is required by many Exchange Manager functions.
  - > `nameP` A pointer to the name of the database that you want `ExgDBWrite` to write. This database is passed to `writeProcP`.
  - > `dbID` The ID of the database that you want `ExgDBWrite` to pass to `writeProcP`. If you don't supply an ID, then `nameP` is used to search for the database by name.
  - > `cardNo` The number of the card on which to look for the database identified by `nameP`.
- Result** Returns `errNone` if successful; otherwise, returns one of the data manager error codes (`dmErr...`) or a callback-specific error code. (If the `writeProcP` function returns an error, it is also returned by `ExgDBWrite`.)
- Comments** This function converts a Palm OS formatted database on the storage heap into a stream of bytes that can be sent over the Internet or over

any other transport mechanism. It is not required that you use this function in conjunction with Exchange Manager calls.

The primary use of this function, however, is to write a database that is going to be beamed onto another device. In this case, call `ExgDBWrite` after establishing the connection with [ExgPut](#). Place the call to [ExgSend](#) in the write callback function you passed as the `writeProcP` parameter. Pass the [ExgSocketType](#) structure returned from `ExgSend` in the `userDataP` parameter so that you have access to it in the write callback function.

The write callback function performs the actual writing of data. `ExgDBWrite` calls the write callback function multiple times. Each time, the `sizeP` parameter contains the number of bytes of `dataP` that are to be written. If the write callback function didn't handle it all, it's important that it set in `sizeP` the number of bytes that it did handle successfully. `ExgDBWrite` stops calling the write callback function after 0 is returned in `sizeP`.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

**See Also**        [ExgDBRead](#)

## ExgDisconnect

**Purpose**            Terminates an Exchange Manager transfer and disconnects.

**Declared In**      `ExgMgr.h`

**Prototype**        `Err ExgDisconnect (ExgSocketType *socketP,  
Err error)`

**Parameters**      `-> socketP`        A pointer to the socket structure (see [ExgSocketType](#)) identifying the connection to terminate.

## Exchange Manager

### Exchange Manager Functions

---

-> error                      Any error that occurred. This parameter tells the exchange library why the connection is being broken. Normally the error code from [ExgSend](#) or [ExgReceive](#) is passed in here.

**Result**                      Returns one of the following error codes:

|                               |                                        |
|-------------------------------|----------------------------------------|
| <code>errNone</code>          | Success                                |
| <code>exgErrBadLibrary</code> | Couldn't find default exchange library |
| <code>exgMemError</code>      | Couldn't read data to send             |
| <code>exgErrUserCancel</code> | User cancelled transfer                |

Other error codes depend on the exchange library.

May display a fatal error message if `socketP` doesn't contain a `libraryRef` value.

**Comments**                      Applications must call this function when finished sending data or receiving data. It terminates the connection made with [ExgConnect](#), [ExgAccept](#), [ExgPut](#), or [ExgGet](#).

In the `error` parameter, pass any error that occurs during the application loop, including errors returned from other Exchange Manager functions. This ensures that the connection is shut down knowing that it failed rather than succeeded.

It's especially important to check the result code from this function, since this will tell you if the transfer was successful. An `errNone` return value means that the item was delivered to the destination successfully. It does not mean that the user on the other end actually kept the data.

`ExgDisconnect` is used after sending and receiving. When receiving, the application can insert its creator ID into the `goToCreator` field in the `socket` structure and add other `goto` information in the `goToParams` field. After the application returns from the [sysAppLaunchCmdExgReceiveData](#) launch code, the exchange library may call [ExgNotifyGoto](#), which launches the `goToCreator` application with the standard launch code [sysAppLaunchCmdGoto](#).

---

**IMPORTANT:** Placing your creator ID in the `goToCreator` field is no longer a guarantee that you receive this launch code starting in Palm OS 4.0 because Palm OS 4.0 supports the sending of multiple objects at once. Thus, another application might overwrite the `goToCreator` field after your application has disconnected, making that application the recipient of the launch code.

---

Note that some exchange libraries wait to establish a connection until `ExgDisconnect` is called. The IR Library, for example, buffers the data that it receives and then waits until `ExgDisconnect` to actually send this data unless `ExgConnect` is called to establish a multi-object send connection.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

Prior to Palm OS release 4.0, the Exchange Manager always launched the `goToCreator` application, if one was provided, upon return from this function. If [4.0 New Feature Set](#) is present, the Exchange Manager does not launch the `goToCreator` application. Exchange libraries that want the previous behavior must explicitly call [ExgNotifyGoto](#).

| <b>Result</b>      | Returns true if the user clicks the OK button on the dialog, or false otherwise.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                           |
| <b>Comments</b>    | This function displays the exchange dialog, which prompts the user to accept or reject incoming data.<br><br>By default, the Exchange Manager calls this function if the receiving application doesn't handle the <a href="#">sysAppLaunchCmdExgAskUser</a> launch code or if it returns exgAskDialog from the launch code handler. When the Exchange Manager calls ExgDoDialog, the dialog displays a message similar to "Do you want to accept 'John Doe' into Address Book?" and allows the user to accept or reject the data. If the user clicks OK, the data should be received as an unfiled record. |                                                                                                                                                                                                                                                                                           |

The Exchange Manager attempts to display a preview of the data in the exchange dialog to provide users with enough information to determine if they want to accept or reject the data. To display the preview data, it calls [ExgNotifyPreview](#). Applications wishing to support preview mode should respond to the launch code [sysAppLaunchCmdExgPreview](#). See the [ExgNotifyPreview](#) function's description for more information.

Applications may also want to allow users to select a category in which to accept the incoming data. To do so, handle [sysAppLaunchCmdExgAskUser](#) to call [ExgDoDialog](#) directly and pass it a pointer to an [ExgDialogInfoType](#) structure. The [ExgDialogInfoType](#) structure is defined as follows:

```
typedef struct {
    UInt16      version;
    DmOpenRef  db;
    UInt16      categoryIndex;
} ExgDialogInfoType;
```

- > version           Set this field to 0 to specify version 0 of this structure.
  
- > db                 A pointer to an open database that defines the categories the dialog should display.
  
- <- categoryIndex     The index of the category in which the user wants to file the incoming data.

If [db](#) is valid, the function extracts the category information from the specified database and displays it in a pop-up list. Upon return, the [categoryIndex](#) field contains the index of the category the user selected, or [dmUnfiledCategory](#) if the user did not select a category.

If the call to [ExgDoDialog](#) is successful, your application is responsible for retaining the value returned in [categoryIndex](#) and using it to file the incoming data as a record in that category. One way to do this is to store the [categoryIndex](#) in the socket's [appData](#) field (see [ExgSocketType](#)) and then extract it from the socket in your response to the launch code [sysAppLaunchCmdExgReceiveData](#). For example:

## Exchange Manager

### Exchange Manager Functions

---

```
if (cmd == sysAppLaunchCmdExgReceiveData) {
    UInt16 category =
        (ExgSocketPtr)cmdPBP->appData;
    /* other declarations */

    /* Receive the data, and create a new record
    using the received data. indexNew is the
    index of this record. */

    if (category != dmUnfiledCategory) {
        UInt16 attr;
        Err err;
        err = DmRecordInfo(dbP, indexNew, &attr,
            NULL, NULL);

        // Set the category to the one the user
        // specified, and mark the record dirty.
        if ((attr & dmRecAttrCategoryMask) !=
            category) {
            attr &= ~dmRecAttrCategoryMask;
            attr |= category | dmRecAttrDirty;
            err = DmSetRecordInfo(dbP, indexNew,
                &attr, NULL);
        }
    }
}
```

Some of the Palm OS built-in applications (Address Book, Memo, and ToDo) use this method of setting the category on data received through beaming. Refer to the example code for these applications provided in the SDK for a more complete example of how to use `ExgDoDialog`.

When you explicitly call `ExgDoDialog`, you must set the `result` field of the `sysAppLaunchCmdExgAskUser` launch code's parameter block to either `exgAskOk` (upon success) or `exgAskCancel` (upon failure) to prevent the system from displaying the dialog a second time.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

Preview mode display in the exchange dialog is implemented only if [4.0 New Feature Set](#) is present.

| <b>Comments</b>               | Applications use this function to request data (initiate a send) from a remote device. Not all exchange libraries support this operation.<br><br>Before calling this function, the application must initialize the <code>socketP</code> parameter. The socket should identify the exchange library to connect with by providing either a library reference number in the <code>libraryRef</code> field or a URL in the <code>name</code> field. The default exchange library registered for the URL's scheme handles |                      |         |                               |                                        |                               |                                  |                          |                                                          |

## Exchange Manager

### *Exchange Manager Functions*

---

the connection. The socket should also specify what data it is requesting by providing values for at least one of the `target`, `name`, and `type` fields. Specifying the data in the `name` field is the most common method.

To provide users with a choice of transport mechanisms, the application can provide a URL that begins with a question mark (?). The Exchange Manager displays a dialog with a list of all exchange libraries that respond to URLs of the specified type. If only one exchange library is registered for this URL scheme, no dialog is displayed.

If the library is not specified by either URL or library reference number, the Exchange Manager by default uses the IR Library; however, if the `localMode` flag is set, the Local Exchange Library is used instead.

Applications can use `ExgGet` to initiate a send from the Local Exchange Library. For more information, see "[Sending and Receiving Locally](#)" on page 32 of the *Palm OS Programmer's Companion*, vol. II, *Communications*.

If no error is returned, applications should follow this call with one or more calls to [ExgReceive](#), to receive the data, or [ExgDisconnect](#), to disconnect.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

| <code>-&gt; dataTypeP</code>  | A pointer to a string that contains the type of data for which to retrieve the default application or library. If <code>dataTypeP</code> is a file extension, do not include the period (.). If it is a URL, do not include the colon (:).                                                                                                                                                                                                                                                                                                                                                                                             |                               |                                                                                     |                       |                                                                                                                               |                              |                                                                                                                                                                                                                                            |
| <b>Result</b>                 | Returns <code>errNone</code> if a match was found or <code>exgErrNoKnownTarget</code> if there is no default application or library for this type of data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                               |                                                                                     |                       |                                                                                                                               |                              |                                                                                                                                                                                                                                            |
| <b>Comments</b>               | <p>You might use this function to see which application on this device will receive a particular type of data or to see which library on this device handles URLs of a particular scheme.</p> <p>For example, to find out which application receives TXT files on this device, do the following:</p> <pre>UInt32 creatorID; Err error; error = ExgGetDefaultApplication(&amp;creatorID,     exgRegExtensionID, "TXT"); if (!error) {     //creatorID contains default application.</pre> <p>To find out which exchange library handles URLs that use the beam prefix, do the following:</p>                                            |                               |                                                                                     |                       |                                                                                                                               |                              |                                                                                                                                                                                                                                            |

## Exchange Manager

### Exchange Manager Functions

---

```
UInt32 creatorID;
Err error;
error = ExgGetDefaultApplication(&creatorID,
    exgRegSchemeID, exgBeamScheme);
if (!error) {
    //creatorID contains default library.
```

It's possible to have several applications registered to receive the same type of data, but none of them is the default. When the Exchange Manager receives an object of that type, it selects an application to receive the data, and it selects that same application every time. The selected application effectively becomes the default for the data type even though it is not explicitly set as the default. If this is the case, the `ExgGetDefaultApplication` function returns the creator ID of this de-facto default application.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgGetRegisteredApplications](#),  
[ExgGetRegisteredTypes](#), [ExgRegisterDatatype](#),  
[ExgSetDefaultApplication](#)

## ExgGetRegisteredApplications

**Purpose** Retrieves a list of all applications registered to receive data of a specified type.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgGetRegisteredApplications  
(UInt32 **creatorIDsP, UInt32 *numAppsP,  
Char **namesP, Char **descriptionsP, UInt16 id,  
const Char *dataTypeP)`

**Parameters** `<- creatorIDsP` An array of the creator IDs of the applications registered to receive objects of this type. Pass NULL for this parameter if you only want to know how many applications are registered for this type.

- `<- numAppsP`      The number of applications registered to receive objects of this type. This is the number of elements in the `creatorIDsP` array, the `namesP` array, and the `descriptionsP` array.
- `<- namesP`      A packed list of strings, suitable for passing to [SysFormPointerArrayToStrings](#), containing the names of the applications or libraries. Each string is no more than `exgMaxTitleLen` characters. Pass `NULL` for this parameter if you don't want to retrieve it.
- `<- descriptionsP`      A packed list of strings, suitable for passing to [SysFormPointerArrayToStrings](#), containing the descriptions of the applications or libraries. Descriptions are specified when the applications or libraries register for data. Each string is no more than `exgMaxDescriptionLength` characters. Pass `NULL` for this parameter if you don't want to retrieve it.
- `-> id`      The registry ID constant identifying the type of data in `dataTypeP`. See [Registry ID Constants](#).
- `-> dataTypesP`      A pointer to a tab-delimited, null-terminated string listing the items to register. (Use `\t` for the tab character.) Each item in the string must be no more than `exgMaxTypeLength` characters. There can be no more than 16 types total.

**Result**      Returns `errNone` upon success or `exgMemError` if the function cannot allocate space for the creator IDs, names, or descriptions.

---

**IMPORTANT:** This function allocates enough space for the `creatorIDsP`, `namesP`, and `descriptionsP` arrays as long as you do not pass `NULL` for the parameters. You are still responsible for freeing these arrays.

---

**Comments** You might use this function to see which applications on this device can receive a particular type of data or to see which libraries on this device handle URLs of a particular scheme. You can also use it to build a list of choices from which the user can select a default application or default exchange library for a particular data type or URL scheme. For example, iMessenger uses this function to build a list of mailto handlers so that the user can choose one of them to be the default.

The Exchange Manager itself uses `ExgGetRegisteredApplications` to find exchange libraries when it is given a URL that begins with a question mark (?). It displays the returned list to the user in the Send With dialog.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgGetDefaultApplication](#), [ExgGetRegisteredTypes](#), [ExgRegisterDatatype](#), [ExgSetDefaultApplication](#)

### ExgGetRegisteredTypes

**Purpose** Retrieve a list of all data types for which a registration exists.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgGetRegisteredTypes (Char **dataTypesP, UInt32 *sizeP, UInt16 id)`

**Parameters**

|                               |                                                                                                                                                                                                                                                |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- dataTypesP</code> | A packed list of strings, suitable for passing to <a href="#">SysFormPointerArrayToStrings</a> , containing a sorted list of data types for which a registration exists. Each string is no more than <code>exgMaxTypeLength</code> characters. |
| <code>&lt;- sizeP</code>      | The number of elements in the <code>dataTypesP</code> array.                                                                                                                                                                                   |

-> id                      The type of data to search for. For example, you can search for all registered creator IDs, all registered MIME types, and so on.

**Result**                  Returns `errNone` upon success or `exgMemError` if the function cannot allocate space for the data types array.

---

**IMPORTANT:** This function allocates enough space for the `dataTypesP` array as long as you do not pass `NULL` for the parameter. You are still responsible for freeing this array.

---

**Comments**                This function could be used to create an application that allows users to choose the default application for each data type.

**Compatibility**            Implemented only if [4.0 New Feature Set](#) is present.

**See Also**                [ExgGetDefaultApplication](#),  
[ExgGetRegisteredApplications](#), [ExgRegisterDatatype](#),  
[ExgSetDefaultApplication](#)

## ExgGetTargetApplication

**Purpose**                    Retrieves the application that should receive a specific message. This function does not search for libraries.

**Declared In**              `ExgMgr.h`

**Prototype**                `Err ExgGetTargetApplication`  
`(ExgSocketType *socketP, Boolean unwrap,`  
`UInt32 *creatorIDP, Char *descriptionP,`  
`UInt32 descriptionSize)`

**Parameters**              -> `socketP`                A pointer to the socket structure (see [ExgSocketType](#)). The structure should contain values for the `target`, `type`, or `name` fields.

## Exchange Manager

### Exchange Manager Functions

---

|                    |                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> unwrap          | If true, only an application that registered to receive the data type with the <code>exgUnwrap</code> flag set should be the target application. If false, the target application should be an application that registered with the <code>exgUnwrap</code> flag clear. |
| <- creatorIDP      | The creator ID of the application that should receive this object.                                                                                                                                                                                                     |
| <-> descriptionP   | The application's description from the registry, if any.                                                                                                                                                                                                               |
| -> descriptionSize | The size of the <code>descriptionP</code> buffer.                                                                                                                                                                                                                      |

**Result** Returns one of the following error codes:

|                                  |                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------|
| <code>errNone</code>             | Success                                                                                         |
| <code>exgErrTargetMissing</code> | The target field contains a creator ID, but the application with that creator ID does not exist |
| <code>exgErrNoKnownTarget</code> | No application is registered to receive the data type                                           |

**Comments** The Exchange Manager uses this function to determine which application should be launched to receive incoming data. Applications and libraries may call this function as well. `ExgGetTargetApplication` determines the target application by doing the following:

- If the `socketP->target` field contains a creator ID, the Exchange Manager searches the registry to see if an application is registered for that creator ID as the default application. If the registry does not contain an entry for the creator ID, it checks to see if the application identified by the creator ID is installed on this device. If an application is found for the target, that is the application returned.
- If the `socketP->type` field contains a MIME type, the Exchange Manager searches the registry for an application

registered to receive objects of that type. If one is found, that is the application returned.

- If the `socketP->name` field contains a period (`.`), the portion after the last period is taken to be the file extension. The Exchange Manager searches the registry for an application registered to receive a file with the specified extension. If one is found, that is the application returned. If not, `exgErrNoKnownTarget` is returned.

If more than one application is registered for the target, type, or file extension, this function returns the one that is registered as the default. If no application is registered as the default, then a specific application is chosen. The Exchange Manager chooses this same application each time. That is, each time a file with a TXT extension is sent with no target or MIME type specified, the `ExgGetTargetApplication` returns the same application to handle the receipt.

Set the `unwrap` parameter to `true` if the object was sent as part of another object, such as a `vStock` object that was sent as an attachment to an e-mail message. In this case, the Exchange Manager searches for an application that registered to receive the target, the type, or the file extension of the `vStock` object with the `exgUnwrap` flag set. If an application is found, the `vStock` object is delivered, and the exchange library should discard the object that contained it (the e-mail message). If there is no application registered to receive the data with the `exgUnwrap` flag set, this function returns `exgErrNoKnownTarget`. In this case, the exchange library should call [ExgNotifyReceive](#) again passing the entire e-mail message instead of just the `vStock` attachment.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

| errNone                                        | Success or the goToCreator field is empty                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                                                                                                                                               |                                                |                                                |                      |                                                                         |
| dmErr... (one of the data manager error codes) | The specified application could not be found                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |                                                                                                                                                                                                                               |                                                |                                                |                      |                                                                         |
| memErrNotEnoughSpace                           | Not enough memory available to create the launch code's parameter block                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                                                                                                                                                                                                               |                                                |                                                |                      |                                                                         |
| <b>Comments</b>                                | <p>Exchange libraries call this function if they want to support immediate display of the received object. Applications do not call this function.</p> <p>Most exchange libraries should call <code>ExgNotifyGoto</code> after the return from <a href="#">ExgNotifyReceive</a> so that the user can inspect the newly received data. If the exchange library is most often used by a single application that does not require the launch code, this call to <code>ExgNotifyGoto</code> can be skipped. For example, the SMS Library does not call <code>ExgNotifyGoto</code>. SMS messages are received by the SMS Messenger application, which does not launch upon receiving data.</p> |            |                                                                                                                                                                                                                               |                                                |                                                |                      |                                                                         |

`ExgNotifyGoto` only launches an application if one is specified in the `goToCreator` field and the `noGoTo` parameter is `false`. If a `goToCreator` is not specified, it is not considered an error. This gives the application a way to override the default behavior.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgNotifyReceive](#), [ExgDisconnect](#)

## ExgNotifyPreview

**Purpose** Displays a preview in the exchange dialog of the data to be received.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgNotifyPreview (ExgPreviewInfoType *infoP)`

**Parameters** `<-> infoP` An [ExgPreviewInfoType](#) structure containing information about the preview operation.

**Result** Returns one of the following error codes:

|                                  |                                                                  |
|----------------------------------|------------------------------------------------------------------|
| <code>errNone</code>             | Success                                                          |
| <code>exgErrNotSupported</code>  | The exchange library doesn't support preview mode                |
| <code>exgErrNoKnownTarget</code> | There is no application registered to receive the type of object |

Other error codes depend on the application.

**Comments** This function performs the preview operation specified in the `op` field of the `infoP` parameter. The [ExgDoDialog](#) function calls this function to show a data preview in the exchange dialog. Exchange libraries might want to call this function in certain circumstances. An application rarely calls this function, but it may do so if it displays its own dialog in response to the launch code [sysAppLaunchCmdExgAskUser](#).

## Exchange Manager

### Exchange Manager Functions

---

ExgNotifyPreview uses [ExgGetTargetApplication](#) to determine the appropriate target application for this data and then launches that application with the launch code [sysAppLaunchCmdExgPreview](#), passing infoP as the parameter block. The application responds to this launch code by accepting the connection, receiving the data from the exchange library, and depending on the operation requested, drawing the data into the infoP->bounds rectangle or returning it in the infoP->string field, and then disconnecting. The ExgDoDialog function uses the returned information to draw the preview portion of the dialog.

If the preview data is a string, the ExgNotifyPreview provides a series of fallback strings that are used if the exchange library doesn't support preview or the application doesn't respond to the launch code. If the application fails to return a string, this function provides one of the following:

- the data's description from socketP->description
- the filename in socketP->name
- the target application's description as stored in the exchange registry
- the MIME type in socketP->type
- the file extension in socketP->name

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgNotifyReceive](#), [ExgDisconnect](#)

## ExgNotifyReceive

**Purpose** Delivers an object to the appropriate application using the registry.

**Declared In** ExgMgr.h

**Prototype** Err ExgNotifyReceive (ExgSocketType \*socketP, UInt16 flags)

**Parameters** <-> socketP A pointer to the socket structure (see [ExgSocketType](#)).

-> flags

A bit field. Pass 0 or a combination of the following constants (OR the constants together to specify more than one):

`exgUnwrap`

The object being delivered should only be handled by an application that registered to receive it with the `exgUnwrap` flag set.

`exgNoAsk`

Do not ask the user to confirm receipt of data. If this constant is passed, the target application does not receive the [sysAppLaunchCmdExgAskUser](#) launch code, and the Exchange Manager does not call [ExgDoDialog](#) to display the user confirmation dialog.

`exgGet`

Specifies that this is a request for the application to send data rather than to receive data.

**Result** Returns one of the following error codes:

`errNone`

Success

`exgErrTargetMissing`

The target field contains a creator ID, but the application with that creator ID does not exist

`exgErrNoKnownTarget`

No application is registered to receive the data type

`exgErrUserCancel`

The user cancelled the operation

Other error codes depend on the application that is launched.

**Comments**

Exchange libraries call this function to initiate a receive operation on the receiving device. Applications do not call this function.

The `ExgNotifyReceive` function uses

[ExgGetTargetApplication](#) to determine which application

## Exchange Manager

### Exchange Manager Functions

---

should receive the data, then sends that application the appropriate launch codes.

If the `flags` parameter is 0, a receive operation is assumed. The `ExgNotifyReceive` function does the following:

1. It sends the application the [sysAppLaunchCmdExgAskUser](#) launch code.
2. If the application returns `exgAskDialog` or does not respond to the launch code, it calls [ExgDoDialog](#), which sends the application the [sysAppLaunchCmdExgPreview](#) launch code to have the application receive preview data for the dialog.
3. It sends the application the [sysAppLaunchCmdExgReceiveData](#) launch code to tell the application to receive the data.

If the `flags` field contains the `exgNoAsk` flag, the first and second steps are skipped.

If the `flags` field contains `exgGet`, this function is a request for data to send to the remote device, not a request to receive data from the remote device. In this case, `ExgNotifyReceive` launches the target application with the [sysAppLaunchCmdExgGetData](#) launch code.

If the `flags` field has the `exgUnwrap` bit set, it means that the object to be received was sent as part of another object, and it should only be sent to an application that registered to receive it with the `exgUnwrap` flag set. For example, if the exchange library receives an e-mail message with an attached vStock object, the exchange library may call `ExgNotifyReceive` with the `exgUnwrap` flag set and a socket that describes the vStock data type to see if there is an application that registered to receive it directly. If no application is registered to receive vStock objects with the `exgUnwrap` flag set, `ExgNotifyReceive` returns `exgErrNoKnownTarget`. The exchange library should then call `ExgNotifyReceive` again, but this time without the `exgUnwrap` flag and with a socket that describes the e-mail message data type. This second call sends the object to the application registered to receive the e-mail message rather than its vStock attachment. That application may extract the vStock attachment from the message and use the Local Exchange Library to send it to an application registered to receive vStock objects normally (without the `exgUnwrap` flag).

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present. `ExgNotifyReceive` was a system use only function until the release of Palm OS 4.0.

If the [4.0 New Feature Set](#) is **not** present, the `flags` parameter is not supported, so libraries cannot suppress the exchange dialog, send objects with attachments, or perform a get operation. These features are all added in the [4.0 New Feature Set](#). Also, if the 4.0 new feature set is not present, this function performs the equivalent of [ExgNotifyGoto](#) after the application has returned from receiving data. Exchange libraries wishing to support this functionality should call `ExgNotifyGoto` immediately after calling `ExgNotifyReceive`.

**See Also** [ExgNotifyPreview](#)

## ExgPut

**Purpose** Initiates the transfer of data to the destination device.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgPut (ExgSocketType *socketP)`

**Parameters** `-> socketP` Pointer to the socket structure (see [ExgSocketType](#)). Specify either a value for the `libraryRef` field or a URL in the `name` field. `libraryRef` should be 0 if the `name` field contains a URL. The structure should also contain a value for the `target`, `type`, or `name` field.

**Result** Returns one of the following error codes:

|                               |                                        |
|-------------------------------|----------------------------------------|
| <code>errNone</code>          | Success                                |
| <code>exgErrBadLibrary</code> | Couldn't find default exchange library |

## Exchange Manager

### Exchange Manager Functions

---

|                                   |                                                                 |
|-----------------------------------|-----------------------------------------------------------------|
| <code>exgMemError</code>          | Not enough memory to initialize transfer                        |
| <code>exgErrNotEnoughPower</code> | The battery does not have enough power to perform the operation |

Other error codes depend on the exchange library.

**Comments** Applications call this function to start a send operation.

If the connection does not already exist, this function establishes one. You must create and initialize an `ExgSocketType` structure containing information about the data to send and the destination application. All unused fields in the structure **must** be set to 0.

If no error is returned, this call **must** be followed by [ExgSend](#), to begin sending data, or [ExgDisconnect](#), to disconnect. You may need to call `ExgSend` multiple times to send all the data.

The socket's `libraryRef` field or the `name` field must identify the library that performs the transfer. The `libraryRef` field identifies the exchange library by its library reference number. The `name` field identifies the library by URL. The socket should also specify what data is being sent by providing values for at least one of the `target`, `name`, and `type` fields. Use of the `name` field is the most common method.

To provide users with a choice of transport mechanisms, the application can provide a URL that begins with a question mark (?). The Exchange Manager displays a dialog with a list of all exchange libraries that respond to URLs of the specified type. If only one exchange library is registered for this URL scheme, no dialog is displayed.

For example, many applications on Palm OS 4.0 or higher support a `Send` command. This command generates a URL with the prefix `exgSendPrefix` (see [Predefined URL Prefixes](#)). The Exchange Manager displays a dialog containing a list of libraries registered for that URL scheme. The user selects an exchange library, and that library's `ExgLibSend` function is called.

If the library is not specified by either URL or library reference number, the Exchange Manager by default uses the IR Library;

however, if the `localMode` flag is set, the Local Exchange Library is used instead.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.  
Support for identifying exchange libraries by URL is implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgDisconnect](#), [ExgSend](#), [ExgConnect](#)

## ExgReceive

**Purpose** Receives data from a remote device.

**Declared In** `ExgMgr.h`

**Prototype** `UInt32 ExgReceive (ExgSocketType *socketP,  
void *bufP, UInt32 bufLen, Err *err)`

**Parameters**

|                            |                                                                         |
|----------------------------|-------------------------------------------------------------------------|
| <code>-&gt; socketP</code> | A pointer to the socket structure (see <a href="#">ExgSocketType</a> ). |
| <code>&lt;- bufP</code>    | A pointer to the buffer in which to receive the data.                   |
| <code>-&gt; bufLen</code>  | The number of bytes to receive.                                         |
| <code>&lt;- err</code>     | A pointer to an error code result.                                      |

**Result** Returns the number of bytes actually received. A zero result indicates the end of the transmission.

An error code is returned in the address indicated by `err`. The error code `exgErrUserCancel` is returned if the user cancels the operation. The error code `exgErrNotSupported` is returned if the application calls this function during a preview and the exchange library does not have any more data available or does not support preview.

May display a fatal error message if the library reference number is not provided in `socketP`.

## Exchange Manager

### Exchange Manager Functions

---

- Comments** Applications call this function in the following circumstances:
- In response to the [sysAppLaunchCmdExgReceiveData](#) launch code, following a successful call to [ExgAccept](#).
  - In response to the [sysAppLaunchCmdExgPreview](#) launch code, following a successful call to [ExgAccept](#).
  - To receive requested data following a successful call to [ExgGet](#).

After receiving the data, applications call [ExgDisconnect](#) to terminate the connection.

This function blocks the application until the end of the transmission or until the requested number of bytes has been received. However, exchange libraries can provide their own user interface that is shown during this call, is updated as necessary, and allows the user to cancel the operation in progress.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present. Preview mode and [ExgGet](#) are only supported if [4.0 New Feature Set](#) is present.

**See Also** [ExgNotifyReceive](#)

## ExgRegisterDatatype

**Purpose** Registers an application to receive a specific type of data, or registers an exchange library to handle specific URL schemes.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgRegisterDatatype (UInt32 creatorID, UInt16 id, const Char *dataTypesP, const Char *descriptionsP, UInt16 flags)`

**Parameters**

|              |                                                                                                                        |
|--------------|------------------------------------------------------------------------------------------------------------------------|
| -> creatorID | The creator ID of the registering application or exchange library.                                                     |
| -> id        | A registry ID constant identifying the type of the items being registered. See <a href="#">Registry ID Constants</a> . |

-> `dataTypesP`      Pointer to a tab-delimited, null-terminated string listing the items to register. (Use "`\t`" for the tab character.) To unregister, pass a `NULL` value. Each item in the string must be no more than `exgMaxTypeLength` characters. There can be no more than 16 types total.

---

**NOTE:** If specifying file extensions, do not include the period (.) that precedes the extension. If specifying URL prefixes, do not include the colon (:) at the end of the prefix.

---

-> `descriptionsP`      Pointer to a tab-delimited, null-terminated string that lists descriptions for the items in the `dataTypesP` parameter. (Use "`\t`" for the tab character.) Each description must be no longer than `exgMaxDescriptionLength`. Pass `NULL` to leave out the descriptions.

There must either be one description for all types or the number of descriptions must match the number of types.

The descriptions are used in dialogs displayed by Exchange Manager to identify applications or libraries.

## Exchange Manager

### Exchange Manager Functions

---

-> flags                      A bit field specifying registration options. Currently, only one bit is used: the unwrap bit. Pass the `exgUnwrap` constant to specify that the application is registering to receive objects of this type directly if the object is sent as part of another object. For example, if a `vStock` object is sent as an attachment to an email message, the Exchange Manager should send the `vStock` object to this application directly rather than sending the message to the email application.

**Result**                      Returns `errNone` if successful, `exgMemError` if there is not enough memory to save the registration info, or one of the data manager error codes (`dmErr...`).

**Comments**                      Both applications and exchange libraries use this function to register with the Exchange Manager to receive certain types of data.

Applications must register with the Exchange Manager to receive data objects that do not specifically target that application using the creator ID in the `target` field.

Exchange libraries register to receive data with certain URL schemes. If an exchange library is not registered to receive URLs, it only handles the receipt and sending of data if its library reference number is explicitly specified in the [ExgSocketType](#) structure. Otherwise, the IR Library handles all incoming data for which a library could not be found.

Both applications and libraries should register to receive data as soon as possible after they are installed and as soon as possible after a hard reset. For example, applications can call `ExgRegisterDatatype` in response to the [sysAppLaunchCmdSyncNotify](#) launch code, which they receive immediately after install. Exchange libraries implemented as applications can also use this strategy. Exchange libraries implemented as shared libraries should call `ExgRegisterDatatype` in their startup functions.

Make only one call to `ExgRegisterDatatype` per registry type. If you want to register to receive multiple items, use a tab character

(\t) to separate the items. If you were to, for example, make one call to register for the DOC file extension and one call to register for the TXT extension, the second call overwrites the first. However, if you want to register with the `exgUnwrap` flag set, make one call without the `exgUnwrap` flag and one call with the `exgUnwrap` flag set. The application registered with the `exgUnwrap` flag set is stored in a different part of the registry.

Specify `exgRegExtensionID` to register to receive data that has a filename with a particular extension. For example, if your application wants to receive files with a TXT extension, it could register like this:

```
ExgRegisterDatatype(myCreator,  
    exgRegExtensionID, "TXT", NULL, 0);
```

If the application wants to receive files with a TXT extension or with a DOC extension, it could register like this:

```
ExgRegisterDatatype(myCreator,  
    exgRegExtensionID, "TXT\tDOC", NULL, 0);
```

Specify `exgRegTypeID` to register to receive data with a specific MIME type. For example, if your application wants to receive "setext" text files, it could register like this:

```
ExgRegisterDatatype(myCreator, exgRegTypeID,  
    "text/x-setext", NULL, 0);
```

Specify `exgRegCreatorID` to register to receive data targeted for a particular creator ID. For example, if your application wants to handle all data intended for the ToDo application, it could register like this:

```
Char todoCreatorStr[5];  
MemMove(todoCreatorStr, sysFileCToDo, 4);  
todoCreatorStr[4] = chrNull;  
ExgRegisterDatatype(myCreator, exgRegCreatorID,  
    todoCreatorStr, NULL, 0);
```

---

**NOTE:** To override one application's receipt of data, you need to also set your application as the default for this creator ID. See [ExgSetDefaultApplication](#).

---

## Exchange Manager

### *Exchange Manager Functions*

---

Most exchange libraries will want to register for a unique URL scheme that identifies only that library, plus they should register for a more general scheme, such as the send scheme (`exgSendScheme`), which causes the library to be listed in the Send With dialog when the user performs the Send command. The registry ID constant for URL prefixes is `exgRegSchemeID`.

```
ExgRegisterDatatype (myLibCreator,  
                    exgRegSchemeID, myScheme "\t" exgSendScheme,  
                    NULL, 0);
```

Registrations are active until a hard reset or until the application or library is removed. The registration information is preserved across a soft reset. When an application is removed, its registry information is also automatically removed from the registry, so there is not normally a need to unregister. If you want to unregister, you can call `ExgRegisterDatatype` with a `NULL` value for the `dataTypesP` parameter.

Multiple applications can be registered to receive the same type of data. If this is the case, the application that is registered as the default (using [ExgSetDefaultApplication](#)) is the one that receives the data unless the exchange socket explicitly specifies another application should receive it. If there is no default specified, the Exchange Manager determines a default.

Multiple libraries may also be registered to receive the same type of URL. In this case, if the URL begins with a question mark (?), the Exchange Manager displays a dialog so that the user can select which exchange library to use. If the URL does not begin with a question mark, the exchange library registered as the default is used. If there is no default specified, the Exchange Manager determines a default.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.  
`ExgRegisterDatatype` replaces the [ExgRegisterData](#) function.

| -> dataTypesP        | Pointer to a tab-delimited, null-terminated string listing the items to register. (Use \t for the tab character.) These include file extensions or MIME types. To unregister, pass a NULL value.                                                                                                                                                                                                                                                                                            |              |                                            |       |                                                                                                            |               |                                                                                                                                                                                                  |
| <b>Result</b>        | Returns errNone if successful, otherwise, one of the data manager error codes (dmErr...).                                                                                                                                                                                                                                                                                                                                                                                                   |              |                                            |       |                                                                                                            |               |                                                                                                                                                                                                  |
| <b>Comments</b>      | Applications that wish to receive data from anything other than another Palm Powered™ handheld running the same application must use this function to register for the kinds of data they can receive. Call this function when your application is loaded on the device.                                                                                                                                                                                                                    |              |                                            |       |                                                                                                            |               |                                                                                                                                                                                                  |
| <b>Compatibility</b> | This function corresponds to the Palm OS 3.5 version of <a href="#">ExgRegisterDatatype</a> . It is implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                     |              |                                            |       |                                                                                                            |               |                                                                                                                                                                                                  |

## ExgRequest

- Purpose** Requests some data from an exchange library or an application using a URL.
- Declared In** `ExgMgr.h`
- Prototype** `Err ExgRequest (ExgSocketType *socketP)`
- Parameters** `-> socketP` Pointer to the socket structure (see [ExgSocketType](#)). Specify a URL in the name field and a `libraryRef` of 0.
- Result** Returns one of the following error codes:
- |                                   |                                                                |
|-----------------------------------|----------------------------------------------------------------|
| <code>errNone</code>              | Success                                                        |
| <code>exgErrBadLibrary</code>     | Couldn't find default exchange library                         |
| <code>exgErrNotEnoughPower</code> | The device does not have enough power to perform the operation |
| <code>sysErrLibNotFound</code>    | Couldn't find library or application to respond to URL         |
- Other error codes depend on the exchange library or application.
- Comments** The `ExgRequest` function is similar to [ExgGet](#) in that both are used to request data. The difference is that the application that calls `ExgGet` is always the application that receives the data. When you call `ExgRequest`, the application that receives the data is the application that is registered to receive it. For example, using `ExgRequest`, it is possible for one application to use the Exchange Manager to retrieve a vCard using any supported transport mechanism and have that data sent directly to the Address Book application instead of to the calling application.
- The `socketP` passed to this function identifies the exchange library using a URL in the name field. The application must know beforehand the proper URL prefix for the exchange library with which it

wants to connect. See [Predefined URL Prefixes](#) for a list of URL prefixes that the Exchange Manager provides.

If the provided URL begins with a question mark (?) and there are several exchange libraries registered for the specified URL scheme, the Exchange Manager displays a dialog from which the user selects the appropriate transport mechanism.

If the Exchange Manager cannot find a library that is registered for the specified URL, it assumes that an application is registered to receive the URL, and it launches that application with the [sysAppLaunchCmdGoToURL](#) launch code.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [ExgGet](#), [ExgNotifyReceive](#)

## ExgSend

**Purpose**          Sends data to the destination device.

**Declared In**    `ExgMgr.h`

**Prototype**      `UInt32 ExgSend (ExgSocketType *socketP,  
const void *bufP, UInt32 bufLen, Err * err)`

**Parameters**    `-> socketP`        A pointer to the socket structure (see [ExgSocketType](#)). A value must be provided for the `libraryRef` field. The structure should also contain values for the `target`, `type`, or `name` fields.

`-> bufP`            A pointer to the data to send.

`-> bufLen`          The number of bytes to send.

`<- err`             A pointer to an error code result.

**Result**          Returns the number of bytes actually sent, normally the same number as specified in `bufLen`. An error code is returned in the address indicated by `err`. The error code `exgErrUserCancel` is returned if the user cancels the operation.

## Exchange Manager

### Exchange Manager Functions

---

May display a fatal error message if the `socketP` parameter does not contain a value for the `libraryRef` field.

**Comments** Call this function one or more times to send all the data, following a successful call to [ExgPut](#). After sending the data, call [ExgDisconnect](#) to terminate the connection.

The exchange library may break large amounts of data into multiple packets or assemble small send commands together into larger packets, but the application will not be aware of these transport level details.

This function blocks the application until all the data is sent. However, the exchange library may provide its own user interface that is updated as necessary and allows the user to cancel the operation in progress.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [ExgReceive](#), [ExgGet](#)

## ExgSetDefaultApplication

**Purpose** Sets the application that receives a specified type of data by default. This function also sets the default exchange library that handles particular URL schemes.

**Declared In** `ExgMgr.h`

**Prototype** `Err ExgSetDefaultApplication (UInt32 creatorID, UInt16 id, const Char *dataTypeP)`

**Parameters**

|                           |                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| -> <code>creatorID</code> | The creator ID of the application or library that should become the default for this type of data.                          |
| -> <code>id</code>        | A registry ID constant identifying the type of data in <code>dataTypeP</code> . See <a href="#">Registry ID Constants</a> . |
| -> <code>dataTypeP</code> | A pointer to a null-terminated string containing the desired type of data.                                                  |

---

**NOTE:** If specifying a file extension, do not include the period (.) that precedes the extension. If specifying a URL prefix, do not include the colon (:) at the end of the prefix.

---

**Result** Returns `errNone` upon success or `exgErrNoKnownTarget` if the specified application is not registered to receive the specified data type.

**Comments** This function sets the default application that receives data of a certain type when no target is specified and the default exchange library that handles URLs with a certain prefix if no library reference number is specified.

Palm™ strongly recommends that applications allow the user to determine which application should become the default recipient for a data type. To do so, an application can use [ExgGetRegisteredApplications](#) to get the list of applications registered for the same type of data as it is, and then display a dialog listing those applications and allow the user to select it. Then it should call `ExgSetDefaultApplication` with the user-specified default.

If you call `ExgSetDefaultApplication` with an application or library that is already the default, this function has no effect.

An application can become the default for its own creator ID even if it has not specifically registered to receive its own creator ID. That is, suppose several applications are registered to receive objects targeted for the `ToDo` application's creator ID. The `ToDo` application itself is not registered for its own creator ID, as it is not necessary to do so. However, an application can use code like the following to set the `ToDo` application as the default for its own creator ID.

```
Char toDoCreatorStr[5];
MemMove(toDoCreatorStr, sysFileCToDo, 4);
toDoCreatorStr[4] = chrNull;
ExgSetDefaultApplication(sysFileCToDo,
    exgRegCreatorID, toDoCreatorStr);
```

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgGetDefaultApplication](#), [ExgRegisterDatatype](#)

## Application-Defined Functions

### ExgDBDeleteProcPtr

**Purpose** Handles the case where a database with an identical name already exists on the device.

**Declared In** `ExgMgr.h`

**Prototype** `Boolean (*ExgDBDeleteProcPtr) (const char* nameP, UInt16 version, UInt16 cardNo, LocalID dbID, void* userDataP)`

**Parameters**

|              |                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> nameP     | A pointer to the name of the identical database.                                                                                                                                                                                                                                                                    |
| -> version   | The version of the identical database.                                                                                                                                                                                                                                                                              |
| -> cardNo    | The card number of the identical database.                                                                                                                                                                                                                                                                          |
| -> dbID      | The database ID of the identical database.                                                                                                                                                                                                                                                                          |
| -> userDataP | The userDataP parameter you passed to <a href="#">ExgDBRead</a> . If used, this parameter contains any application-specific data you find necessary. If the <a href="#">ExgDBReadProcPtr</a> function is implemented using Exchange Manager calls, this often contains the <a href="#">ExgSocketType</a> structure. |

**Result** Return `true` to have the `ExgDBRead` function continue to read the database. Use this return value if you have deleted or moved the existing database or if you want the database to be overwritten. Return `false` to have `ExgDBRead` exit without reading the database.

**Comments** This function is called if the Data Manager can't create the incoming database because a database with the same name already exists. You should delete the existing database or take some other action, such as changing the database name. It is appropriate to prompt the user before choosing to delete or move the database.

## **ExgDBReadProcPtr**

**Purpose** Reads in the database and pass it to [ExgDBRead](#).

**Declared In** `ExgMgr.h`

**Prototype** `Err (*ExgDBReadProcPtr) (void* dataP, UInt32* sizeP, void* userDataP)`

**Parameters**

|                              |                                                                                                                                                                                                                                                           |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- dataP</code>     | A pointer to a buffer where this function should place the database data. This buffer is allocated in the dynamic heap by <code>ExgDBRead</code> ; you don't need to use <a href="#">DmWrite</a> when filling it.                                         |
| <code>&lt;-&gt; sizeP</code> | The size of <code>dataP</code> . This value is set by <code>ExgDBRead</code> to the number of bytes it expects to receive in <code>dataP</code> . You must set this value to the number of bytes you return in <code>dataP</code> (if it's not the same). |
| <code>-&gt; userDataP</code> | The <code>userDataP</code> parameter you passed to <code>ExgDBRead</code> . Pass the <a href="#">ExgSocketType</a> structure if you implement this function using Exchange Manager calls.                                                                 |

**Result** Return an error number, or `errNone` if there is no error. If this function returns an error, `ExgDBRead` deletes the database it was creating, cleans up any memory it allocated, then exits, returning the error passed back from this function.

**Comments** `ExgDBRead` is commonly used to receive a database from a beam or from some other transport mechanism. In this case, an appropriate implementation of this callback function is to call [ExgReceive](#) as shown here:

## Exchange Manager

### Application-Defined Functions

---

```
Err MyReadDBProc (void *dataP, UInt32 *sizeP,
                 void *userDataP)
{
    Err err = errNone;

    //userDataP contains ExgSocketType pointer.
    *sizeP =
        ExgReceive((ExgSocketType *)userDataP,
                  dataP, *sizeP, &err);
    return err;
}
```

## ExgDBWriteProcPtr

- Purpose** Writes out the database.
- Declared In** ExgMgr.h
- Prototype** Err (\*ExgDBWriteProcPtr) (const void\* dataP, UInt32\* sizeP, void\* userDataP)
- Parameters**
- |              |                                                                                                                                                                                                               |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> dataP     | A pointer to a buffer containing the database data, placed there by <a href="#">ExgDBWrite</a> .                                                                                                              |
| <-> sizeP    | The number of bytes placed in dataP by ExgDBWrite. If you were unable to write out or send all of the data in this chunk, on exit, set sizeP to the number of bytes you did write.                            |
| -> userDataP | The userDataP parameter you passed to ExgDBWrite. You can use it for application-specific data. Pass the <a href="#">ExgSocketType</a> structure if you implement this function using Exchange Manager calls. |
- Result** Return an error number, or errNone if there is no error. If this function returns an error, ExgDBWrite closes the database it was reading, cleans up any memory it allocated, then exits, returning the error passed back from this function.

**Comments** ExgDBWrite is commonly used to write a database that is going to be beamed to another device (or sent through some other transport mechanism). In this case, an appropriate implementation of this callback function is to call [ExgSend](#) as shown here:

```
Err MyWriteDBProc (void *dataP, UInt32 *sizeP,
                  void *userDataP)
{
    Err err = errNone;

    //userDataP contains ExgSocketType pointer.
    *sizeP =
        ExgSend((ExgSocketType *)userDataP,
                dataP, *sizeP, &err);
    return err;
}
```

## **Exchange Manager**

*Application-Defined Functions*

---

# Exchange Library

---

The Exchange Library API described in this chapter and declared in `ExgLib.h` specifies a minimal set of functions that all exchange libraries must implement. This chapter is directed towards developers who use or create exchange libraries. Developers creating an exchange library should also read the [Exchange Libraries](#) chapter of the *Palm OS Programmer's Companion*, vol. II, *Communications*.

## Exchange Library Functions

### ExgLibAccept

|                    |                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Accept an incoming connection.                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>ExgLib.h</code>                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <code>Err ExgLibAccept(UInt16 libRefnum,<br/>ExgSocketType *exgSocketP)</code>                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p>-&gt; <code>libRefnum</code>      Reference number of this exchange library.</p> <p>-&gt; <code>exgSocketP</code>      A pointer to the socket structure (see <a href="#">ExgSocketType</a>).</p>                                                                                                    |
| <b>Result</b>      | Returns <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if a preview is in progress and the exchange library does not support preview. Other error codes are defined by each exchange library.                                                                            |
| <b>Comments</b>    | The Exchange Manager's <a href="#">ExgAccept</a> function simply calls <code>ExgLibAccept</code> in the exchange library identified by the <a href="#">ExgSocketType</a> structure passed to <code>ExgAccept</code> . An application calls the Exchange Manager's <code>ExgAccept</code> function when: |

## Exchange Library

### Exchange Library Functions

---

- The application wants to initiate a connection to receive data, which it does in response to `sysAppLaunchCmdExgReceiveData`.
- The application wants to initiate a connection to receive a preview of the data, which it does in response to `sysAppLaunchCmdExgAskUser`.

Any implementation of `ExgLibAccept` should update any progress dialogs to indicate that data is being accepted (or received) into an application.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgLibPut](#)

## ExgLibClose

**Purpose** Library-specific. Although this function is not called by the Exchange Manager, all shared libraries normally implement it.

**Declared In** `ExgLib.h`

**Prototype** `Err ExgLibClose (UInt16 libRefnum)`

**Parameters** `-> libRefnum` Reference number of this exchange library.

**Comments** Exchange libraries are free to implement this function for internal or external use. The Exchange Manager does not call it.

## ExgLibConnect

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                              |                                            |                                   |                                                                                                                                |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|--------------------------------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>                    | Open a connection in preparation for sending or receiving objects.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                              |                                            |                                   |                                                                                                                                |
| <b>Declared In</b>                | <code>ExgLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                              |                                            |                                   |                                                                                                                                |

## Exchange Library

### Exchange Library Functions

---

The Exchange Manager's `ExgConnect` function calls `ExgLibConnect` in the exchange library identified by the [ExgSocketType](#) structure passed to `ExgConnect`. If `ExgLibConnect` is implemented to return `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; the exchange library must put up its own alerts when appropriate.

The exchange library may prompt the user for addressing information.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibControl

**Purpose** Supply information about the exchange library.

**Declared In** `ExgLib.h`

**Prototype** `Err ExgLibControl(UInt16 libRefNum, UInt16 op, void *valueP, UInt16 *valueLenP)`

**Parameters**

|               |                                                      |
|---------------|------------------------------------------------------|
| -> libRefNum  | Reference number of this exchange library.           |
| -> op         | The operation to perform.                            |
| <-> valueP    | An operation specific parameter. See comments below. |
| <-> valueLenP | An operation specific parameter. See comments below. |

**Result** Returns `errNone` if no error. `exgErrNotSupported` is returned if the specified operation is not supported by the exchange library. `exgErrBadParam` is returned if the parameters (`valueP` and `valueLenP`) are not appropriate for the operation. Additional error codes are defined by each exchange library.

**Comments** `ExgLibControl` is a general purpose function that performs various minor operations based upon a selector. `ExgMgr.h` defines

three selectors: `exgLibCtlGetTitle`, which should be supported by all exchange libraries, `exgLibCtlGetVersion`, and `exgLibCtlGetPreview`. Additional library-specific selectors should be numbered starting at `exgLibCtlSpecificOp` (0x8000).

Upon receiving `exgLibCtlGetTitle`, the exchange library must return a library title suitable for use in Exchange Manager dialogs. Exchange libraries that are built as applications should generally return their 'tAIN' resource as their title. Be sure that the title returned through `valueP` honors the maximum length specified in `valueLenP`.

An exchange library that implements the Palm OS 4.0 version of the Exchange Library API needn't do anything special upon receiving `exgLibCtlGetVersion`; it should simply return `exgErrNotSupported`. Otherwise, set `valueP` to a two-byte value indicating the API version number and return `errNone`. Note that a version number of zero corresponds to the Palm OS 4.0 version of the Exchange Library API.

The `exgLibCtlGetPreview` operation is used by the Exchange Manager to determine whether a given exchange library supports preview. The Exchange Manager assumes that an exchange library supports preview if the exchange library doesn't implement this operation. To indicate that a library does not support preview, set `valueP` to `false` and return `errNone`.

The Exchange Manager's [ExgControl](#) function simply calls `ExgLibControl` in the exchange library identified by the [ExgSocketType](#) structure passed to `ExgControl`.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibDisconnect

- Purpose** Disconnect a connection made with [ExgLibConnect](#), [ExgLibAccept](#), [ExgLibPut](#), or [ExgLibGet](#).
- Declared In** `ExgLib.h`
- Prototype** `Err ExgLibDisconnect (UInt16 libRefnum, ExgSocketType *exgSocketP, Err error)`
- Parameters**
- > `libRefnum` Reference number of this exchange library.
  - > `exgSocketP` A pointer to an [ExgSocketType](#) structure identifying the socket connection to be disconnected.
  - > `error` The current error state. Used to indicate why the connection is being broken, for example, user cancel or out of memory.
- Result** Typically the same error code passed in. However, this function may return an error even if `errNone` is passed in.
- Comments** `ExgLibDisconnect` may be used to finish reading the data during a preview; in this case, the connection, if any, is not shut down.
- Applications call `ExgLibDisconnect` when all data has been sent or the application wants to stop the send process. If the send data process is not completed, the caller should pass an error parameter indicating why the operation was stopped. `ExgLibDisconnect` is responsible for completing the operation and closing any communication ports if necessary. If data was buffered for sending in `ExgLibSend`, then the disconnect process may actually perform the entire transmit operation. It is important to note that the `ExgLibDisconnect` function can be called for an `ExgLibPut`, `ExgLibAccept` or `ExgLibGet` function. So it is equally important to keep track of the current operation in the [ExgSocketType](#). If dialogs are displayed, this function must update them as appropriate. If there are errors, `ExgLibDisconnect` should display them (if allowed by the application).

If [ExgLibConnect](#) is not supported, the first call to [ExgLibPut](#) must clean up after itself before returning an error and the exchange library should not expect to get an [ExgLibDisconnect](#) call.

If [ExgLibConnect](#) is supported and an application calls [ExgConnect](#), the exchange library should delay any cleanup until [ExgLibDisconnect](#), unless [ExgLibConnect](#) returns an error, in which case it should clean up after itself. The library can expect to get an [ExgLibDisconnect](#) call if it returns `errNone` from [ExgLibConnect](#). If the application does not call [ExgConnect](#), the first call to [ExgLibPut](#) must clean up after itself before returning an error and the exchange library should not expect to get an [ExgLibDisconnect](#) call.

The Exchange Manager's [ExgDisconnect](#) function simply calls [ExgLibDisconnect](#) in the exchange library identified by the [ExgSocketType](#) structure passed to [ExgDisconnect](#).

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibGet

|                                   |                                                                                                                                                                                                                                                    |                              |                                            |                                   |                                                                         |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|--------------------------------------------|-----------------------------------|-------------------------------------------------------------------------|
| <b>Purpose</b>                    | Establish a connection and request data from a remote device.                                                                                                                                                                                      |                              |                                            |                                   |                                                                         |
| <b>Declared In</b>                | <code>ExgLib.h</code>                                                                                                                                                                                                                              |                              |                                            |                                   |                                                                         |
| <b>Prototype</b>                  | <pre>Err ExgLibGet (UInt16 libRefNum,<br/>ExgSocketType *exgSocketP)</pre>                                                                                                                                                                         |                              |                                            |                                   |                                                                         |
| <b>Parameters</b>                 | <table><tr><td><code>-&gt; libRefNum</code></td><td>Reference number of this exchange library.</td></tr><tr><td><code>&lt;-&gt; exgSocketP</code></td><td>A pointer to the socket structure (see <a href="#">ExgSocketType</a>).</td></tr></table> | <code>-&gt; libRefNum</code> | Reference number of this exchange library. | <code>&lt;-&gt; exgSocketP</code> | A pointer to the socket structure (see <a href="#">ExgSocketType</a> ). |
| <code>-&gt; libRefNum</code>      | Reference number of this exchange library.                                                                                                                                                                                                         |                              |                                            |                                   |                                                                         |
| <code>&lt;-&gt; exgSocketP</code> | A pointer to the socket structure (see <a href="#">ExgSocketType</a> ).                                                                                                                                                                            |                              |                                            |                                   |                                                                         |
| <b>Result</b>                     | Returns <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if this operation is not supported by this library. Other error codes are defined by each exchange library.                                                  |                              |                                            |                                   |                                                                         |
| <b>Comments</b>                   | <code>ExgLibGet</code> informs the library that it should make a connection to the remote device and request information from it. When an                                                                                                          |                              |                                            |                                   |                                                                         |

## Exchange Library

### Exchange Library Functions

---

exchange library's `ExgLibGet` function is called, it should fetch the requested data and prepare to deliver it when the application calls [ExgReceive](#). After [ExgLibReceive](#) is called, possibly more than once, [ExgLibDisconnect](#) follows.

The Exchange Manager's [ExgGet](#) function calls `ExgLibGet` in the exchange library identified in the [ExgSocketType](#) structure passed to `ExgGet`. If an exchange library's implementation of `ExgLibGet` returns `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; an exchange library must put up its own alerts when appropriate.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibHandleEvent

**Purpose** Handle exchange-library-specific events.

**Declared In** `ExgLib.h`

**Prototype** `Boolean ExgLibHandleEvent (UInt16 libRefnum,  
void *eventP)`

**Parameters**

|                              |                                            |
|------------------------------|--------------------------------------------|
| <code>-&gt; libRefnum</code> | Reference number of this exchange library. |
| <code>-&gt; eventP</code>    | The event to handle.                       |

**Result** Returns `true` if the event was handled.

**Comments** Exchange libraries are free to implement this function for internal or external use. The Exchange Manager does not call it.

## **ExgLibOpen**

- Purpose** Library-specific. Although this function is not called by the Exchange Manager, all shared libraries normally implement it.
- Declared In** `ExgLib.h`
- Prototype** `Err ExgLibOpen (UInt16 libRefnum)`
- Parameters** `-> libRefnum` Reference number of this exchange library.
- Comments** Exchange libraries are free to implement this function for internal or external use. The `ExgLibDisconnect` does not call it.

## Exchange Library

### Exchange Library Functions

---

## ExgLibPut

- Purpose** Signals the start of an object to be transferred to the destination device.
- Declared In** `ExgLib.h`
- Prototype** `Err ExgLibPut (UInt16 libRefnum,  
ExgSocketType *exgSocketP)`
- Parameters**
- > `libRefnum` Reference number of this exchange library.
  - <- `exgSocketP` Pointer to the socket structure (see [ExgSocketType](#)).
- Result** Returns `errNone` if no error. Error codes are defined by each exchange library.
- Comments** Opens a connection if necessary. The actual data should be sent using [ExgLibSend](#) after which the connection should be shut down with [ExgLibDisconnect](#). The exchange library may prompt the user for addressing information.
- The first time this library is called, it may be necessary to allocate global variables and perform other initialization steps. It is usually a good idea to keep any state information about the open connection in the `socketRef` field of the `exgSocketP` structure. This data can then be passed to subsequent operations on that socket.
- `ExgLibPut` should then check if the `socketRef` field of `exgSocketP` has been initialized. In some cases, an application may already have filled `socketRef` with addressing information. The use of `socketRef` is entirely up to the exchange library. If `socketRef` is empty, the exchange library needs to fill in any addressing information. In order to do this, the exchange library needs to open its own dialog asking the user for whatever addressing information would be appropriate.
- Exchange libraries are responsible for any validation of data entered in the addressing dialog and may use Address Book lookup or other system features to improve the user experience.

Once the user has completed addressing and confirmed the dialog, the exchange library should, in general, call the [Progress Manager](#) to open a progress dialog that remains open during the entire put operation. The progress dialog should not be opened if the `noStatus` option was passed or if the transaction is in asynchronous mode.

If the exchange library is displaying dialogs, it must also look for events and pass them to the Progress Manager.

Other operations within `ExgLibPut` depend on the exchange library. The exchange library may open communications ports and establish remote links at this time. Or it may just open a stream for buffering data until a later operation. If any errors occur in this process, the exchange library is responsible for removing any progress dialogs and returning an error. If displaying progress, the exchange library may also need to display an error using the Progress Manager before returning.

---

**NOTE:** The progress dialog is converted to an error dialog and waits until the user dismisses it. This may occur in `ExgLibPut` or later in [ExgLibDisconnect](#). It depends on whether the connection was made in `ExgLibPut` or whether it used an existing connection made by a previous call to `ExgLibConnect` or `ExgLibPut`.

---

The first call to [ExgLibPut](#) must clean up after itself before returning an error if one of the following conditions exists:

- If [ExgLibConnect](#) is not supported.
- If `ExgLibConnect` is supported and an application does not call `ExgLibConnect`.

The Exchange Manager's [ExgPut](#) function calls `ExgLibPut` in the exchange library identified by the [ExgSocketType](#) structure passed to `ExgPut`. If `ExgLibPut` returns `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; an exchange library must put up its own alerts when appropriate.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **ExgLibReceive**

**Purpose** Receive data from a remote device.

**Declared In** ExgLib.h

**Prototype** `UInt32 ExgLibReceive( UInt16 libRefNum,  
ExgSocketType *exgSocketP, void *bufP,  
UInt32 bufSize, Err *errP)`

**Parameters**

|                |                                                                                                                                                                                                                                                                                                                                  |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> libRefNum   | Reference number of this exchange library.                                                                                                                                                                                                                                                                                       |
| <-> exgSocketP | A pointer to the socket structure (see <a href="#">ExgSocketType</a> ).                                                                                                                                                                                                                                                          |
| -> bufP        | A pointer to a buffer into which the data is put.                                                                                                                                                                                                                                                                                |
| -> bufSize     | The size of the buffer in bytes.                                                                                                                                                                                                                                                                                                 |
| <- errP        | The error code result: <code>errNone</code> if no error. <code>exgErrNotSupported</code> is returned if used during a preview and the exchange library does not support preview or if there appears to be more data available but <code>ExgLibReceive</code> cannot obtain it. Error codes are defined by each exchange library. |

**Result** The number of bytes received. Returns 0 if the object is complete. `ExgLibReceive` blocks until at least one byte is available or the object is complete.

**Comments** Use after [ExgLibGet](#) or [ExgLibAccept](#) to receive the contents of the object. May be used after `ExgLibAccept` to examine the contents during a preview.

`ExgLibReceive` must update any progress dialogs to indicate that data is being received. The `ExgLibReceive` should fill the buffer passed as much as possible and return the actual number of bytes that were stored in the buffer. `ExgLibReceive` must block for at

least one byte if the stream is not complete. Returning zero bytes indicates the end of the data.

The Exchange Manager's [ExgReceive](#) function simply calls `ExgLibReceive` in the exchange library identified by the [ExgSocketType](#) structure passed to `ExgReceive`.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibRequest

**Purpose** Requests an object using a URL, then has the Exchange Manager send it to the default application registered for the object's type.

**Declared In** `ExgLib.h`

**Prototype**

```
Err ExgLibRequest(UInt16 libRefNum,  
ExgSocketType *socketP)
```

**Parameters**

|                                |                                                                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; libRefNum</code>   | Reference number of this exchange library.                                                                                           |
| <code>&lt;-&gt; socketP</code> | Pointer to the socket structure (see <a href="#">ExgSocketType</a> ). The name field contains the URL of the object being requested. |

**Result** Returns `errNone` if no error. `exgErrNotSupported` is returned if the exchange library does not support this operation. Other error codes are defined by each exchange library.

**Comments** The exchange library may prompt the user for addressing information. The socket's name field may contain a URL with any of the schemes for which the exchange library registered. Not all exchange libraries support this operation.

---

**NOTE:** This function is often used to tickle an exchange library to make it check to see if there are new messages. These messages are then delivered as usual. So there may or may not be a specific object being requested.

---

## Exchange Library

### Exchange Library Functions

---

The Exchange Manager's [ExgRequest](#) function calls `ExgLibRequest` in the exchange library identified by the `ExgSocketType` structure passed to `ExgRequest`. If `ExgLibRequest` returns `exgErrNotEnoughPower`, the Exchange Manager puts up an alert, so there is no need for the exchange library to do so. Other error codes are not treated specially by the Exchange Manager; an exchange library must put up its own alerts when appropriate.

**See Also** [ExgRegisterDatatype](#)

## ExgLibSend

**Purpose** Send data for an object to a destination device.

**Declared In** `ExgLib.h`

**Prototype** `UInt32 ExgLibSend(UInt16 libRefNum,  
ExgSocketType *exgSocketP, const void *bufP,  
UInt32 bufLen, Err *errP)`

**Parameters**

|                            |                                                                         |
|----------------------------|-------------------------------------------------------------------------|
| -> <code>libRefNum</code>  | Reference number of this exchange library.                              |
| <- <code>exgSocketP</code> | A pointer to the socket structure (see <a href="#">ExgSocketType</a> ). |
| -> <code>bufP</code>       | A pointer to a buffer containing the data to send.                      |
| -> <code>bufLen</code>     | The number of bytes to send.                                            |
| <- <code>errP</code>       | The error code result. Error codes are defined by each exchange library |

**Result** Returns the number of bytes sent.

**Comments** Applications call [ExgSend](#) after [ExgPut](#) and in response to `sysAppLaunchCmdExgGetData`.

This function blocks until all bytes to be sent are actually sent, or until an error occurs (such as device full).

ExgLibSend may be called any number of times with varying size buffers to transmit information. If dialogs are being displayed, ExgLibSend must keep them updated (perhaps with animation or progress information). ExgLibSend must also check for events and let the Progress Manager handle them.

The Exchange Manager's ExgSend function simply calls ExgLibSend in the exchange library identified by the [ExgSocketType](#) structure passed to ExgSend.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## ExgLibSleep

**Purpose**    The device is going to sleep.

**Declared In**    ExgLib.h

**Prototype**    Err ExgLibSleep(UInt16 libRefnum)

**Parameters**    -> libRefnum      Reference number of this exchange library.

**Result**    Returns errNone if no error. Error codes are defined by each exchange library.

**Comments**    The device goes into sleep mode when the user turns the device off, the auto-off timer expires, or power is low. All shared libraries must implement ExgLibSleep; however, no processing is required and simply returning errNone is enough.

---

**IMPORTANT:** Libraries must return from this function quickly to allow sufficient time for emergency shutdown situations (removal of batteries, for example).

---

## **ExgLibWake**

- Purpose** The device is waking up.
- Declared In** `ExgLib.h`
- Prototype** `Err ExgLibWake(UInt16 libRefnum)`
- Parameters** `-> libRefnum` Reference number of this exchange library.
- Result** Returns `errNone` if no error. Error codes are defined by each exchange library.
- Comments** The device wakes up when the user turns the device on. All shared libraries must implement `ExgLibWake`, although no processing is required; it is enough to simply return `errNone`.

# IR Library

---

The IR (InfraRed) library is a shared library that provides a direct interface to the IR communications capabilities of the Palm OS®. This chapter provides reference material for the IR library API:

- [IR Library Data Structures](#)
- [IR Library Constants](#)
- [IR Stack Callback Events](#)
- [IR Library Functions](#)
- [IAS Functions](#)
- [Application-Defined Functions](#)

The header file `irlib.h` declares the IR library API. For more information on the IR library, see the chapter “[Beaming \(Infrared Communication\)](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## IR Library Data Structures

This section lists some of the more important data types used by the IR library functions.

### IrConnect

The `IrConnect` structure is used to manage an IrLMP or Tiny TP connection.

```
typedef struct _hconnect {
    UInt8 lLsap;
    UInt8 rLsap;
    UInt8 flags;
    UInt8 reserved;
    IrCallback callback;
    IrPacket packet;
    ListEntry packets;
}
```

## IR Library

### IR Library Data Structures

---

```
    UInt16 sendCredit;  
    UInt8  availCredit;  
    UInt8  dataOff;  
} _hconnect;
```

#### Field Descriptions

|             |                                                    |
|-------------|----------------------------------------------------|
| lLsap       | The local LSAP on which this connection listens.   |
| rLsap       | The LSAP assigned to the remote side.              |
| flags       | For system use only.                               |
| reserved    | Reserved for future use.                           |
| callBack    | Pointer to callback function. For system use only. |
| packet      | For system use only.                               |
| packets     | List of packets to send.                           |
| sendCredit  | Amount of credit from peer.                        |
| availCredit | Amount of credit to give to peer.                  |
| dataOff     | Amount of data less than IrLAP size.               |

#### IrPacket

The IrPacket structure is used for sending IrDA packets.

```
typedef struct _IrPacket {  
    ListEntry node;  
    UInt8 *buff;  
    UInt16 len;  
    IrConnect* origin;  
    UInt8 headerLen;  
    UInt8 header[14];  
    UInt8 reserved;  
} IrPacket;
```

#### Field Descriptions

|      |                                  |
|------|----------------------------------|
| node | For system use only.             |
| buff | Pointer to the send data buffer. |

|           |                                                                  |
|-----------|------------------------------------------------------------------|
| len       | Number of bytes in data buffer.                                  |
| origin    | Pointer to connection that owns the packet. For system use only. |
| headerLen | Number of bytes contained in the header. For system use only.    |
| header    | Storage for header. For system use only.                         |
| reserved  | Reserved for future use.                                         |

---

**IMPORTANT:** The `node` field must be the first field in the structure. It is used internally by the stack.

---

## **IrIASObject**

The `IrIASObject` structure is used as storage for an IAS object managed by the local IAS server. An object of this type is passed as the `obj` parameter to the [IrIAS\\_Add](#) function.

```
typedef struct _IrIasObject {
    UInt8 *name;
    UInt8 len;
    UInt8 nAttribs;
    IrIasAttribute* attribs;
} IrIasObject;
```

### **Field Descriptions**

|          |                                    |
|----------|------------------------------------|
| name     | Pointer to name of object.         |
| len      | Length of object name.             |
| nAttribs | Number of attributes.              |
| attribs  | Pointer to an array of attributes. |

## IrlasQuery

The `IrIasQuery` structure is used to perform IAS queries. The `IrIasQuery` object is passed as the token parameter to functions such as [IrIAS\\_Query](#) and [IrIAS\\_Next](#).

```
typedef struct _IrIasQuery {
    UInt8 queryLen;
    UInt8 reserved;
    UInt8 *queryBuf;
    UInt16 resultBufSize;
    UInt16 resultLen;
    UInt16 listLen;
    UInt16 offset;
    UInt8 retCode;
    UInt8 overFlow;
    UInt8 *result;
    IrIasQueryCallBack callBack;
} _IrIasQuery;
```

### Field Descriptions

|                            |                                                                 |
|----------------------------|-----------------------------------------------------------------|
| <code>queryLen</code>      | Total length of the query.                                      |
| <code>reserved</code>      | Reserved for future use.                                        |
| <code>queryBuf</code>      | Pointer to buffer containing the query.                         |
| <code>resultBufSize</code> | Size of the result buffer.                                      |
| <code>resultLen</code>     | Actual number of bytes in the result buffer.                    |
| <code>listLen</code>       | Number of items in the result list.                             |
| <code>offset</code>        | Offset into the results buffer.                                 |
| <code>retCode</code>       | Return code of operation.                                       |
| <code>overFlow</code>      | Set to <code>true</code> if result exceeded result buffer size. |
| <code>result</code>        | Pointer to buffer containing result.                            |
| <code>callBack</code>      | Pointer to query callback function.                             |

## IrCallbackParms

The IrCallbackParms structure is used to pass information from the stack to the upper layer of the stack (application). Not all fields are valid at any given time. The type of event determines which fields are valid. The IrCallbackParms object is passed as the second parameter to the IrCallback function.

```
typedef struct {
    IrEvent event;
    UInt8 reserved1;
    UInt8 *rxBuff;
    UInt16 rxLen;
    IrPacket* packet;
    IrDeviceList* deviceList;
    IrStatus status;
    UInt8 reserved2;
} IrCallBackParms;
```

### Field Descriptions

|            |                                    |
|------------|------------------------------------|
| event      | Event causing the callback.        |
| reserved1  | Reserved for future use.           |
| rxBuff     | Received data buffer.              |
| rxLen      | Length of data in received buffer. |
| packet     | Pointer to packet being returned.  |
| deviceList | Pointer to discovery device list.  |
| status     | Status of stack.                   |
| reserved2  | Reserved for future use.           |

## IrStatsType

The IrStatsType structure defines performance statistics for the IR Library. Use the [ExgControl](#) function with an irGetStatistics operation to retrieve these statistics. See [IR Control Constants](#) for more information.

```
typedef struct {
    UInt16 recLineErrors;
    UInt16 crcErrors;
} IrStatsType;
```

### Field Descriptions

`recLineErrors` The number of serial errors since the library opened.

`crcErrors` The number of CRC errors since the library opened.

## IR Library Constants

### IR Control Constants

The IR control constants define operations that the IR Exchange Library can perform. You pass these constants as the operation parameter to [ExgControl](#). The following table lists the operation constants, the data that should be passed as the `valueP` parameter to `ExgControl`, and what operation is performed in response.

---

| Operation Constant             | value Data Type                            | Description                                                                                                                                                                                                |
|--------------------------------|--------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irGetScanningMode</code> | Boolean. Output only.                      | Returns <code>true</code> in <code>*valueP</code> if beaming is enabled or <code>false</code> if beaming is disabled.                                                                                      |
| <code>irGetStatistics</code>   | <a href="#">IrStatsType</a> . Output only. | Returns performance statistics.                                                                                                                                                                            |
| <code>irRestoreScanning</code> | None                                       | Re-enables beaming after an <code>irSuppressScanning</code> operation. This operation keeps track of the number of requests that beaming be disabled and re-enables beaming only when the count reaches 0. |

---

| Operation Constant             | value Data Type                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irSetScanningMode</code> | Boolean. Input only.                                                                                                   | <p>This operation differs from <code>irSetScanningMode</code> in that it does not update the saved preferences.</p> <p>Enables or disables beaming.</p> <p>This operation modifies the saved preferences database, which is back up during a HotSync<sup>®</sup> operation. Because of this, beaming may remain disabled after a reset if you use this operation to disable it. If you want to temporarily disable beaming use <code>irSuppressScanning</code> and <code>irRestoreScanning</code> instead.</p>                                                                                                                   |
| <code>irSetBaudMask</code>     | UInt16 containing a mask of the <code>irOpenOptSpeed...</code> constants defined in <code>IrLib.h</code> . Input only. | <p>Sets the possible baud rates that the IR Library will use to those specified in <code>*valueP</code>. OR the <code>irOpenOptSpeed...</code> constants together to specify more than one. The default rate is 0, which causes the baud rate to be determined by the hardware.</p> <p>This operation is sometimes useful for debugging connections. Generally, you should set all bits up to the fastest rate you want to allow. To reset, use this operation again and pass 0 in <code>*valueP</code>.</p> <p>If you change the baud rate, your changes are until the device is reset or you perform this operation again.</p> |

| <b>Operation Constant</b>       | <b>value Data Type</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>irSetSerialMode</code>    | Boolean. Input only.   | If the specified value is <code>true</code> , the IR Library uses the serial port instead of the infrared port until the device is reset. This option is useful for debugging. You can run your application in POSE and use the IR Library to communicate with a device connected in the cradle.                                     |
| <code>irSetSupported</code>     | Boolean. Input only.   | If <code>true</code> , IR is supported on this device. If <code>false</code> , IR is not supported. You can use this constant to disable the unsupported dialog that normally displays when a beam is attempted and no IR support is available.                                                                                      |
| <code>irSuppressScanning</code> | None                   | Temporarily disables beam receive. This operation keeps track of the number of requests that beaming be disabled and re-enables beaming (through <code>irRestoreScanning</code> ) only when the count reaches 0.<br><br>This operation differs from <code>irSetScanningMode</code> in that it does not update the saved preferences. |

---

## IR Stack Callback Events

The IR stack calls the application by way of a callback function stored in each [IrConnect](#) structure. The callback function is called with a pointer to the `IrConnect` structure and a pointer to a parameter structure. The parameter structure contains an event field, which indicates the reason the callback is called, and other parameters, which have meaning based on the event.

The meaning of the events is described in the following sections.

### **LEVENT\_DATA\_IND**

Data has been received. The received data is accessed using fields `rxBuff` and `rxLen`.

### **LEVENT\_DISCOVERY\_CNF**

Indicates the completion of a discovery operation. The field `deviceList` points to the discovery list.

### **LEVENT\_LAP\_CON\_CNF**

The requested IrLAP connection has been made successfully. The callback function of all bound `IrConnect` structures is called.

### **LEVENT\_LAP\_CON\_IND**

Indicates that the IrLAP connection has come up. The callback of all bound `IrConnect` structures is called.

### **LEVENT\_LAP\_DISCON\_IND**

Indicates that the IrLAP connection has gone down. This means that all IrLMP connections are also down. A callback with event `LEVENT_LM_CON_IND` is not given. The callback function of all bound `IrConnect` structures is called.

### **LEVENT\_LM\_CON\_CNF**

The requested IrLMP/Tiny TP connection has been made successfully. Connection data from the other side is found using fields `rxBuff` and `rxLen`.

### **LEVENT\_LM\_CON\_IND**

Other device has initiated a connection. `IrConnectRsp` should be called to accept the connection. Any data associated with the connection request can be found using fields `rxBuff` and `rxLen`, data pointer and length, respectively.

## **LEVENT\_LM\_DISCON\_IND**

The IrLMP/Tiny TP connection has been disconnected. Any data associated with the disconnect indication can be found using fields `rxBuff` and `rxLen`, data pointer and length, respectively.

## **LEVENT\_PACKET\_HANDLED**

A packet is being returned. A pointer to the packet exists in field `packet`.

## **LEVENT\_STATUS\_IND**

Indicates that a status event from the stack has occurred. The `status` field indicates the status generating the event. Possible status values are as follows:

- `IR_STATUS_NO_PROGRESS` which means that IrLAP has no progress for 3 seconds threshold time (for example, the beam is blocked).
- `IR_STATUS_LINK_OK` which indicates that the no progress condition has cleared.
- `IR_STATUS_MEDIA_NOT_BUSY` which indicates that the IR media has transitioned from busy to not busy.

## **LEVENT\_TEST\_CNF**

Indicates that a TEST command has completed. The `status` field indicates if the test was successful.

- `IR_STATUS_SUCCESS` indicates that the operation was successful and the data in the test response can be found by using the `rxBuff` and `rxLen` fields.
- `IR_STATUS_FAILED` indicates that no TEST response was received. The packet passed to perform the test command is passed back in the `packet` field and is now available (no separate packet handled event occurs).

## **LEVENT\_TEST\_IND**

Indicates that a TEST command frame has been received. A pointer to the received data is in `rxBuff` and `rxLen`. A pointer to the

packet that is sent in response to the test command is in the packet field. The packet is currently set up to respond with the same data sent in the command TEST frame. If different data is desired as a response, then you need to modify the packet structure. This event is sent to the callback function in all bound `IrConnect` structures. The IAS connections ignore this event.

## IR Library Functions

### **IrAdvanceCredit**

|                      |                                                                                                                                                                                            |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Advances the credit to the other side of the connection.                                                                                                                                   |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                                                       |
| <b>Prototype</b>     | <code>void IrAdvanceCredit (IrConnect* con,<br/>UInt8 credit)</code>                                                                                                                       |
| <b>Parameters</b>    | <code>--&gt; con</code> Pointer to <a href="#">IrConnect</a> structure representing connection to which credit is advanced.<br><br><code>--&gt; credit</code> Amount of credit to advance. |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                           |
| <b>Comments</b>      | The credit passed by this function is added to the existing available credit, which must not exceed 127. This function only makes sense for a Tiny TP connection.                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                        |

## **IrBind**

|                              |                                                                                                                                                                                                                                                                                                                                                                                                         |                            |                    |                             |                                                 |                              |                                                                                                       |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|--------------------|-----------------------------|-------------------------------------------------|------------------------------|-------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>               | Obtains a local LSAP selector and registers the connection with the protocol stack.                                                                                                                                                                                                                                                                                                                     |                            |                    |                             |                                                 |                              |                                                                                                       |

|                    |                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Starts an IrLAP connection.                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | <code>IrStatus IrConnectIrLap (UInt16 refNum,<br/>IrDeviceAddr deviceAddr)</code>                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | --> <code>refnum</code> IR library <code>refNum</code> .<br>--> <code>deviceAddr</code> 32-bit address of device to which connection should be made.                                                                                                                                                                                                                |
| <b>Result</b>      | <code>IR_STATUS_PENDING</code> means the operation started successfully; the result is returned by way of a callback.<br><br><code>IR_STATUS_MEDIA_BUSY</code> means the operation failed because the media is busy. Media busy is caused by one of the following reasons: <ul style="list-style-type: none"><li>• Other devices are using the IR medium.</li></ul> |

- An IrLAP connection already exists.
- A discovery process is in progress.

**Comments** The result is signaled to all bound `IrConnect` structures by way of the callback function. The callback event is `LEVENT_LAP_CON_CNF` if successful or `LEVENT_LAP_DISCON_IND` if unsuccessful.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrConnectReq**

**Purpose** Requests an IrLMP or Tiny TP connection.

**Declared In** `IrLib.h`

**Prototype** `IrStatus IrConnectReq (UInt16 refNum,  
IrConnect* con, IrPacket* packet, UInt8 credit)`

**Parameters**

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--&gt; refnum</code> | IR library refNum.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>--&gt; con</code>    | Pointer to <a href="#">IrConnect</a> structure for handling the connection. The <code>rLsap</code> field must contain the LSAP selector for the peer on the other device. Also the type of the connection must be set. Use <code>IR_SetConTypeLMP</code> to set the type to an IrLMP connection or <code>IR_SetConTypeTTP</code> to set the type to a Tiny TP connection.                                                                           |
| <code>--&gt; packet</code> | Pointer to a packet that contains connection data. Even if no connection data is needed, the packet must point to a valid <a href="#">IrPacket</a> structure. The packet is returned by way of the callback function with the <code>LEVENT_PACKET_HANDLED</code> event if no errors occur. The maximum size of the packet is <code>IR_MAX_CON_PACKET</code> for an IrLMP connection or <code>IR_MAX_TTP_CON_PACKET</code> for a Tiny TP connection. |

--> `credit`      Initial amount of credit advanced to the other side. Must be less than 127. It is ANDed with 0x7f, so if it is greater than 127, unexpected results occur. This parameter is ignored if the connection is an IrLMP connection.

**Result**      `IR_STATUS_PENDING` means the operation has been started successfully and the result is returned by way of the callback function with the event `LEVENT_LM_CON_CNF` if the connection is made or `LEVENT_LM_DISCON_IND` if connection fails. The packet is returned by way of the callback with the event `LEVENT_PACKET_HANDLED`.

`IR_STATUS_FAILED` means the operation failed because of one of the following reasons. Note that the packet is available immediately.

- The connection is busy (already involved in a connection).
- The `IrConnect` structure is not bound to the stack.
- The packet size exceeds maximum allowed.

`IR_STATUS_NO_IRLAP` means the operation failed because there is no IrLAP connection (the packet is available immediately).

**Comments**      The result is signaled by way of the callback specified in the `IrConnect` structure. The callback event `LEVENT_LM_CON_CNF` indicates that the connection is up and `LEVENT_LM_DISCON_IND` indicates that the connection failed. Before calling this function the fields in the `con` structure must be properly set.

**Compatibility**      Implemented only if [3.0 New Feature Set](#) is present.

## **IrConnectRsp**

- Purpose** Accepts an incoming connection that has been signaled by way of the callback with the event `LEVENT_LM_CON_IND`.
- Declared In** `IrLib.h`
- Prototype** `IrStatus IrConnectRsp (UInt16 refNum, IrConnect* con, IrPacket* packet, UInt8 credit)`
- Parameters**
- |                            |                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--&gt; refnum</code> | IR library refNum.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>--&gt; con</code>    | Pointer to <a href="#">IrConnect</a> structure.                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>--&gt; packet</code> | Pointer to a packet that contains connection data. Even if no connection data is needed, the packet must point to a valid <a href="#">IrPacket</a> structure. The packet is returned by way of the callback with the <code>LEVENT_PACKET_HANDLED</code> event if no errors occur. The maximum size of the packet is <code>IR_MAX_CON_PACKET</code> for an IrLMP connection or <code>IR_MAX_TTP_CON_PACKET</code> for a Tiny TP connection. |
| <code>--&gt; credit</code> | Initial amount of credit advanced to the other side. Must be less than 127. It is ANDed with <code>0x7f</code> , so if it is greater than 127, unexpected results occur. This parameter is ignored if the connection is an IrLMP connection.                                                                                                                                                                                               |
- Result** `IR_STATUS_PENDING` means the operation has been started successfully and the packet is returned by way of the callback function with the event `LEVENT_PACKET_HANDLED`.
- `IR_STATUS_FAILED` means the operation failed because of one of the following reasons. Note that the packet is available immediately.
- The connection is not in the proper state to require a response.
  - The `IrConnect` structure is not bound to the stack.

- The packet size exceeds the maximum allowed.

IR\_STATUS\_NO\_IRLAP means the operation failed because there is no IrLAP connection (the packet is available immediately).

**Comments** IrConnectRsp can be called during the callback or later to accept the connection. The type of the connection must already have been set to IrLMP or Tiny TP before the LEVENT\_LM\_CON\_IND event.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrDataReq

**Purpose** Sends a data packet.

**Declared In** IrLib.h

**Prototype** IrStatus IrDataReq (UInt16 refNum,  
IrConnect\* con, IrPacket\* packet)

**Parameters**

|            |                                                                                                                                                                          |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --> refnum | IR library refNum.                                                                                                                                                       |
| --> con    | Pointer to <a href="#">IrConnect</a> structure that specifies the connection over which the packet should be sent.                                                       |
| --> packet | Pointer to a valid <a href="#">IrPacket</a> structure that contains data to send. The packet should not exceed the maximum size found with <a href="#">IrMaxTxSize</a> . |

**Result** IR\_STATUS\_PENDING means the packet has been queued by the stack. The packet is returned by way of the callback with event LEVENT\_PACKET\_HANDLED.

IR\_STATUS\_FAILED means the operation failed because of one of the following reasons. Note that the packet is available immediately.

- The IrConnect structure is not bound to the stack.
- The packet size exceeds the maximum allowed.

- The `IrConnect` structure does not represent an active connection.

**Comments** The packet is owned by the stack until it is returned by way of the callback with event `LEVENT_PACKET_HANDLED`. The largest packet that can be sent is found by calling [IrMaxTxSize](#).

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrDisconnectIrLap**

**Purpose** Disconnects an IrLAP connection.

**Declared In** `IrLib.h`

**Prototype** `IrStatus IrDisconnectIrLap (UInt16 refNum)`

**Parameters** `--> refnum` IR library `refNum`.

**Result** `IR_STATUS_PENDING` means the operation started successfully and all bound `IrConnect` structures are called back when complete.

`IR_STATUS_NO_IRLAP` means the operation failed because no IrLAP connection exists.

**Comments** When the IrLAP connection goes down, the callback of all bound `IrConnect` structures is called with event `LEVENT_LAP_DISCON_IND`.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrDiscoverReq

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Starts an IrLMP discovery process.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>     | <code>IrStatus IrDiscoverReq (UInt16 refNum,<br/>IrConnect* con)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>    | <code>--&gt; refnum</code> IR library refNum.<br><code>--&gt; con</code> Pointer to a bound <a href="#">IrConnect</a> structure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Result</b>        | <code>IR_STATUS_PENDING</code> means the operation is started successfully; the result is returned by way of callback.<br><br><code>IR_STATUS_MEDIA_BUSY</code> means the operation failed because the media is busy. Media busy is caused by one of the following reasons: <ul style="list-style-type: none"><li>• Other devices are using the IR medium.</li><li>• A discovery process is already in progress.</li><li>• An IrLAP connection exists.</li></ul> <code>IR_STATUS_FAILED</code> means the operation failed because the <code>IrConnect</code> structure is not bound to the stack. |
| <b>Comments</b>      | The result is signaled by way of the callback function specified in the <code>IrConnect</code> structure with the event <code>LEVENT_DISCOVERY_CNF</code> . Only one discovery can be invoked at a time.                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## **IrlsIrLapConnected**

- Purpose** Determines if an IrLAP connection exists.
- Declared In** `IrLib.h`
- Prototype** `BOOL IrIsIrLapConnected (UInt16 refNum)`
- Parameters** `--> refnum` IR library `refNum`.
- Result** `true` if IrLAP is connected, `false` otherwise.
- Comments** Only available if `IR_IS_LAP_FUNCS` is defined.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrlsMediaBusy**

- Purpose** Determines if the IR media is busy.
- Declared In** `IrLib.h`
- Prototype** `BOOL IrIsMediaBusy (UInt16 refNum)`
- Parameters** `--> refnum` IR library `refNum`.
- Result** `true` if IR media is busy, `false` otherwise.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrlsNoProgress**

- Purpose** Determines if IrLAP is not making progress.
- Declared In** IrLib.h
- Prototype** `BOOL IrIsNoProgress (UInt16 refNum)`
- Parameters** --> refnum            IR library refNum.
- Result**            true if IrLAP is not making progress, false otherwise.
- Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrlsRemoteBusy**

- Purpose** Determines if IrLAP of the other device is busy.
- Declared In** IrLib.h
- Prototype** `BOOL IrIsRemoteBusy (UInt16 refNum)`
- Parameters** --> refnum            IR library refNum.
- Result**            true if IrLAP of the other device is busy, false otherwise.
- Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrLocalBusy**

- Purpose** Sets the IrLAP local busy flag.
- Declared In** IrLib.h
- Prototype** `void IrLocalBusy (UInt16 refNum, BOOL flag)`
- Parameters** --> refnum            IR library refNum.

--> flag            Value (`true` or `false`) to set for local busy flag of IrLAP.

**Result**        Returns nothing.

**Comments**     If local busy is set to `true`, then the local IrLAP layer sends RNR (Receive Not Ready) frames to the other side indicating it cannot receive any more data. If the local busy is set to `false`, IrLAP is ready to receive frames.

The setting takes effect the next time IrLAP sends an RR (Receive Ready) frame. If IrLAP has data to send, the data is sent first, so it should be used carefully.

This function should not be used when using Tiny TP or when multiple connections exist.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

## **IrMaxRxSize**

**Purpose**        Returns the maximum size buffer that can be sent by the other device.

**Declared In**    `IrLib.h`

**Prototype**     `UInt16 IrMaxRxSize (UInt16 refNum,  
IrConnect* con)`

**Parameters**    --> `refnum`        IR library `refNum`.  
--> `con`            Pointer to [IrConnect](#) structure that represents an active connection.

**Result**        Returns the maximum size buffer that can be sent by the other device (maximum bytes that can be received). The value returned is only valid for active connections. The maximum size varies for each connection and is based on the negotiated IrLAP parameters and the type of the connection.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrMaxTxSize**

**Purpose** Returns the maximum size allowed for a transmit packet.

**Declared In** IrLib.h

**Prototype** UInt16 IrMaxTxSize (UInt16 refNum,  
IrConnect\* con)

**Parameters** --> refnum IR library refNum.  
--> con Pointer to [IrConnect](#) structure that represents an active connection.

**Result** Returns the maximum size allowed for a transmit packet. The value returned is only valid for active connections. The maximum size varies for each connection and is based on the negotiated IrLAP parameters and the type of the connection.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrOpen**

**Purpose** Opens the IR library. This allocates the global memory for the IR stack and reserves the system resources it requires. This must be done before any other IR library calls are made.

**Declared In** IrLib.h

**Prototype** Err IrOpen (UInt16 refnum, UInt32 options)

**Parameters** --> refnum IR library refNum. This value is returned from the function [SysLibFind](#), which you must call first to load the IR library.

--> `options`      Open options flags. See the Comments section for details.

**Result**      Returns 0 if successful.

**Comments**      The following flags can be specified for the `options` parameter to set the speed of the connection:

`irOpenOptSpeed115200`      Set to maximum negotiated baud rate.

`irOpenOptSpeed57600`      Set to 57600 bps (default if no flags given).

`irOpenOptSpeed9600`      Set to 9600 bps.

**Compatibility**      Implemented only if [3.0 New Feature Set](#) is present.

## **IrSetConTypeLMP**

**Purpose**      Sets the type of the connection to IrLMP. This function must be called after the `IrConnect` structure is bound to the stack.

**Declared In**      `IrLib.h`

**Prototype**      `void IrSetConTypeLMP (IrConnect* con)`

**Parameters**      --> `con`      Pointer to [IrConnect](#) structure.

**Result**      Returns nothing.

**Compatibility**      Implemented only if [3.0 New Feature Set](#) is present.

## IrSetConTypeTTP

- Purpose** Sets the type of the connection to Tiny TP. This function must be called after the `IrConnect` structure is bound to the stack.
- Declared In** `IrLib.h`
- Prototype** `void IrSetConTypeTTP (IrConnect* con)`
- Parameters** `--> con` Pointer to [IrConnect](#) structure.
- Result** Returns nothing.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrSetDeviceInfo

- Purpose** Sets the XID info string used during discovery to the given string and length.
- Declared In** `IrLib.h`
- Prototype** `IrStatus IrSetDeviceInfo (UInt16 refNum, UInt8 *info, UInt8 len)`
- Parameters** `--> refnum` IR library `refNum`.  
`--> info` Pointer to array of bytes.  
`--> len` Number of bytes pointed to by `info`.
- Result** `IR_STATUS_SUCCESS` means the operation is successful.  
`IR_STATUS_FAILED` means the operation failed because `info` is too big.
- Comments** The XID `info` string contains hints and the nickname of the device. The size cannot exceed `IR_MAX_DEVICE_INFO` bytes.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrTestReq**

**Purpose** Requests a TEST command frame be sent in the NDM (Normal Disconnect Mode) state.

**Declared In** IrLib.h

**Prototype** IrStatus IrTestReq (UInt16 refNum,  
IrDeviceAddr devAddr, IrConnect\* con,  
IrPacket\* packet)

**Parameters**

|             |                                                                                                                                                                                                                                         |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| --> refnum  | IR library refNum.                                                                                                                                                                                                                      |
| --> devAddr | Address of device where TEST is sent. This address is not checked so it can be the broadcast address or 0.                                                                                                                              |
| --> con     | Pointer to <a href="#">IrConnect</a> structure specifying the callback function to call to report the result.                                                                                                                           |
| --> packet  | Pointer to an <a href="#">IrPacket</a> structure that contains the data to send in the TEST command packet. The maximum size data that can be sent is IR_MAX_TEST_PACKET. Even if no data is to be sent, a valid packet must be passed. |

**Result** IR\_STATUS\_PENDING means the operation has been started successfully and the result is returned by way of the callback function with the event LEVENT\_TEST\_CNF. This is also the indication returning the packet.

IR\_STATUS\_FAILED means the operation failed because of one of the following reasons. Note that the packet is available immediately.

- The IrConnect structure is not bound to the stack.
- The packet size exceeds the maximum allowed.

IR\_STATUS\_MEDIA\_BUSY means the operation failed because the media is busy or the stack is not in the NDM state (the packet is available immediately).

**Comments** The result is signaled by way of the callback specified in the `IrConnect` structure. The callback event is `LEVENT_TEST_CNF` and the status field indicates the result of the operation. `IR_STATUS_SUCCESS` indicates success and `IR_STATUS_FAILED` indicates no response was received. A packet must be passed containing the data to send in the TEST frame. The packet is returned when the `LEVENT_TEST_CNF` event is given.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrUnbind

**Purpose** Unbinds the `IrConnect` structure from the protocol stack, freeing its LSAP selector.

**Declared In** `IrLib.h`

**Prototype** `IrStatus IrUnbind (UInt16 refNum, IrConnect* con)`

**Parameters**

|                            |                                                           |
|----------------------------|-----------------------------------------------------------|
| <code>--&gt; refnum</code> | IR library refNum.                                        |
| <code>--&gt; con</code>    | Pointer to <a href="#">IrConnect</a> structure to unbind. |

**Result** `IR_STATUS_SUCCESS` means the operation completed successfully. `IR_STATUS_FAILED` means the operation failed for one of the following reasons:

- The `IrConnect` structure was not bound.
- The `lLsap` field contained an invalid number.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IAS Functions

This section describes the following functions and macros related to IAS database:

- [IrIAS\\_Add](#)
- [IrIAS\\_GetInteger](#)

- [IrIAS\\_GetIntLsap](#)
- [IrIAS\\_GetObjectID](#)
- [IrIAS\\_GetOctetString](#)
- [IrIAS\\_GetOctetStringLength](#)
- [IrIAS\\_GetType](#)
- [IrIAS\\_GetUserString](#)
- [IrIAS\\_GetUserStringCharSet](#)
- [IrIAS\\_GetUserStringLength](#)
- [IrIAS\\_Next](#)
- [IrIAS\\_Query](#)
- [IrIAS\\_SetDeviceName](#)
- [IrIAS\\_StartResult](#)

## **IrIAS\_Add**

- Purpose** Adds an IAS object to the IAS Database.
- Declared In** IrLib.h
- Prototype** IrStatus IrIAS\_Add (UInt16 refNum,  
IrIasObject\* obj)
- Parameters**
- > refnum IR library refNum.
  - > obj Pointer to an [IrIASObject](#) structure.
- Result** IR\_STATUS\_SUCCESS means the operation is successful.  
IR\_STATUS\_FAILED means the operation failed for one of the following reasons:
- There is no space in the database.
  - An entry with the same class name already exists.
  - The attributes of the object violate the IrDA Lite rules (attribute name exceeds IR\_MAX\_IAS\_NAME, or attribute value exceeds IR\_MAX\_IAS\_ATTR\_SIZE).

- The class name exceeds `IR_MAX_IAS_NAME`.

**Comments** The object is not copied, so the memory for the object must exist for as long as the object is in the database. The IAS database is designed to allow only objects with unique class names, and it checks for this. Class names and attributes names must not exceed `IR_MAX_IAS_NAME`. Also, attribute values must not exceed `IR_MAX_IAS_ATTR_SIZE`.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_GetInteger**

**Purpose** Macro to return an integer value, assuming that the current result item is of type `IAS_ATTRIB_INTEGER`. (Call [IrIAS\\_GetType](#) to determine the type of the current result item.)

**Declared In** `IrLib.h`

**Prototype** `IrIAS_GetInteger (t)`

**Parameters** `--> t` Pointer to an [IrIasQuery](#) structure.

**Result** Integer value returned as a `UInt32`.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_GetIntLsap**

**Purpose** Macro to return an integer value that represents an LSAP, assuming that the current result item is of type `IAS_ATTRIB_INTEGER`. (Call

[IrIAS\\_GetType](#) to determine the type of the current result item.)  
Usually integer values returned in a query are LSAP selectors.

**Declared In** IrLib.h

**Prototype** IrIAS\_GetIntLsap (t)

**Parameters** --> t Pointer to an [IrIasQuery](#) structure.

**Result** Integer value returned as a UInt8.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

### **IrIAS\_GetObjectID**

**Purpose** Macro to return the unique object ID of the current result item.

**Declared In** IrLib.h

**Prototype** IrIAS\_GetObjectID (t)

**Parameters** --> t Pointer to an [IrIasQuery](#) structure.

**Result** Returns the object ID as a UInt16 type.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IriAS\_GetOctetString

- Purpose** Macro to return a pointer to an octet string, assuming that the current result item is of type IAS\_ATTRIB\_OCTET\_STRING. (Call [IriAS\\_GetType](#) to determine the type of the current result item.)
- Declared In** IrLib.h
- Prototype** IriAS\_GetOctetString (t)
- Parameters** --> t                      Pointer to an [IriAsQuery](#) structure.
- Result** Pointer to octet string of type UInt8.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IriAS\_GetOctetStringLength

- Purpose** Macro to return the length of an octet string, assuming that the current result item is of type IAS\_ATTRIB\_OCTET\_STRING. (Call [IriAS\\_GetType](#) to determine the type of the current result item.)
- Declared In** IrLib.h
- Prototype** IriAS\_GetOctetStringLength (t)
- Parameters** --> t                      Pointer to an [IriAsQuery](#) structure.
- Result** Length of octet string returned as a UInt16.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IriAS\_GetType

- Purpose** Macro to return the type of the current result item.
- Declared In** IrLib.h
- Prototype** IrIAS\_GetType (t)
- Parameters** --> t                      Pointer to an [IrIasQuery](#) structure.
- Result** Type of result item, such as IAS\_ATTRIB\_INTEGER, IAS\_ATTRIB\_OCTET\_STRING or IAS\_ATTRIB\_USER\_STRING. The return value is of type UInt8.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IriAS\_GetUserString

- Purpose** Macro to return a pointer to a user string, assuming that the current result item is of type IAS\_ATTRIB\_USER\_STRING. (Call [IrIAS\\_GetType](#) to determine the type of the current result item.)
- Declared In** IrLib.h
- Prototype** IrIAS\_GetUserString (t)
- Parameters** --> t                      Pointer to an [IrIasQuery](#) structure.
- Result** Pointer to result string of type UInt8.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IriAS\_GetUserStringCharSet

- Purpose** Macro to return the character set of the user string, assuming that the current result item is of type IAS\_ATTRIB\_USER\_STRING.

(Call [IrIAS\\_GetType](#) to determine the type of the current result item.)

- Declared In** IrLib.h
- Prototype** IrIAS\_GetUserStringCharSet (t)
- Parameters** --> t Pointer to an [IrIasQuery](#) structure.
- Result** Character set returned as an IrCharSet value.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

### **IrIAS\_GetUserStringLen**

**Purpose** Macro to return the length of a user string, assuming that the current result item is of type IAS\_ATTRIB\_USER\_STRING. (Call [IrIAS\\_GetType](#) to determine the type of the current result item.)

- Declared In** IrLib.h
- Prototype** IrIAS\_GetUserStringLength (t)
- Parameters** --> t Pointer to an [IrIasQuery](#) structure.
- Result** Length of user string returned as a UInt8 value.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_Next**

|                      |                                                                                                                                        |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Moves the internal pointer to the next result item.                                                                                    |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                                                                                   |
| <b>Prototype</b>     | <code>UInt8* IrIAS_Next (UInt16 refNum,<br/>IrIasQuery* token)</code>                                                                  |
| <b>Parameters</b>    | --> <code>refnum</code> IR library <code>refNum</code> .<br>--> <code>token</code> Pointer to an <a href="#">IrIasQuery</a> structure. |
| <b>Result</b>        | Pointer to the next result item, or 0 if there are no more items.                                                                      |
| <b>Comments</b>      | This function returns a pointer to the start of the next result item. If the pointer is 0, then there are no more result items.        |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                    |

## **IrIAS\_Query**

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Makes an IAS query of the IAS database of another device.                                                                                                                                                                                |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <code>IrStatus IrIAS_Query (UInt16 refNum,<br/>IrIasQuery* token)</code>                                                                                                                                                                 |
| <b>Parameters</b>  | --> <code>refnum</code> IR library <code>refNum</code> .<br>--> <code>token</code> Pointer to an <a href="#">IrIasQuery</a> structure initialized as described in the Comments section.                                                  |
| <b>Result</b>      | <code>IR_STATUS_SUCCESS</code> means the operation is started successfully and the result is signaled by way of the callback function.<br><br><code>IR_STATUS_FAILED</code> means the operation failed for one of the following reasons: |

- The query exceeds `IR_MAX_QUERY_LEN`.
- The `result` field of `token` is 0.
- The `resultBufSize` field of `token` is 0.
- The `callback` field of `token` is 0.
- A query is already in progress.

`IR_STATUS_NO_IRLAP` means the operation failed because there is no IrLAP connection.

**Comments** An IrLAP connection must exist to the other device. The IAS query token must be initialized as described below. The result is signaled by calling the callback function whose pointer exists in the `IrIasQuery` structure. Only one query can be made at a time.

The `IrIasQuery` structure passed in the `token` parameter must be initialized as follows:

- Assign a pointer to a callback function in which the result is signaled.
- Set `result` to point to a buffer large enough to hold the result of the query.
- Set `resultBufSize` to the size of the result buffer.
- Set `queryBuf` to point to a valid query.
- Set `queryLen` to the number of bytes in `queryBuf`. The length must not exceed `IR_MAX_QUERY_LEN`.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **IrIAS\_SetDeviceName**

**Purpose** Sets the `value` field of the device name attribute of the “Device” object in the IAS database.

**Declared In** `IrLib.h`

**Prototype** `IrStatus IrIAS_SetDeviceName (UInt16 refNum, UInt8 *name, UInt8 len)`

**Parameters**

|                            |                                                                                                                                                                                                                                                                                                                           |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>--&gt; refnum</code> | IR library <code>refNum</code> .                                                                                                                                                                                                                                                                                          |
| <code>--&gt; name</code>   | Pointer to an IAS <code>value</code> field for the device name attribute of the device object. It includes the attribute type, character set and device name. This <code>value</code> field should be a constant and the pointer must remain valid until <code>IrIAS_SetDeviceName</code> is called with another pointer. |
| <code>--&gt; len</code>    | Total length of the <code>value</code> field. Maximum size allowed is <code>IR_MAX_IAS_ATTR_SIZE</code> .                                                                                                                                                                                                                 |

**Result** `IR_STATUS_SUCCESS` means the operation is successful.  
`IR_STATUS_FAILED` means `len` is too big, or the `value` field is not a valid user string.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## IrIAS\_StartResult

|                      |                                                                                |
|----------------------|--------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro to put the internal pointer to the start of the result buffer.           |
| <b>Declared In</b>   | <code>IrLib.h</code>                                                           |
| <b>Prototype</b>     | <code>IrIAS_StartResult (t)</code>                                             |
| <b>Parameters</b>    | --> t                      Pointer to an <a href="#">IrIasQuery</a> structure. |
| <b>Result</b>        | Returns nothing.                                                               |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.            |

## Application-Defined Functions

The functions in this section are supplied by the developer and can be named anything.

### IrlasQueryCallback

|                    |                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Signals the result of IAS query. The result of IAS queries is signaled by calling this callback function which is pointed to by the <code>callBack</code> field of the <a href="#">IrIasQuery</a> structure.                                                                                   |
| <b>Declared In</b> | <code>IrLib.h</code>                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | <code>void IrIasQueryCallBack (IrStatus status)</code>                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | --> status                      The status of the query operation. The following values can be passed:<br><br>IR_STATUS_SUCCESS means the query operation finished successfully and the results can be parsed.<br><br>IR_STATUS_DISCONNECT means the link or IrLMP connection was disconnected |

## IR Library

### *Application-Defined Functions*

---

during the query, so the results are not valid.

**Result** Returns nothing.

# Modem Manager

---

This chapter provides reference material for the modem manager API. The header file `ModemMgr.h` declares the modem manager API.

## Modem Manager Functions

### MdmDial

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                           |                     |                                                       |                      |                                                                     |                        |                                                      |                        |                                |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|-------------------------------------------------------|----------------------|---------------------------------------------------------------------|------------------------|------------------------------------------------------|------------------------|--------------------------------|
| <b>Purpose</b>         | Initialize the modem, dial the phone number and wait for result.                                                                                                                                                                                                                                                                                                                                                                          |                     |                                                       |                      |                                                                     |                        |                                                      |                        |                                |
| <b>Declared In</b>     | <code>ModemMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                   |                     |                                                       |                      |                                                                     |                        |                                                      |                        |                                |

| <b>Comments</b>        | <p>When executing this function, the system performs these steps:</p> <ul style="list-style-type: none"> <li>• Switch to the requested initial baud rate.</li> <li>• If HW hand-shake is requested, enable CTS/RTS hand-shaking; otherwise, disable it.</li> </ul>                                                                                                                                                                        |                     |                                                       |                      |                                                                     |                        |                                                      |                        |                                |

## Modem Manager

### *Modem Manager Functions*

---

- Reset the modem.
- Execute the setup string (if any).
- Configure the modem with required settings.
- Dial the phone number.
- Wait for CONNECT XXXXX or other response.
- If auto-baud is requested, switch to the connected baud rate.

## MdmHangUp

**Purpose** Hang up the modem.

**Declared In** `ModemMgr.h`

**Prototype** `Err MdmHangUp (MdmInfoPtr modemP)`

**Parameters** `modemP` Pointer to modem info structure (filled in by caller)

**Result** 0 if successful.

---

**WARNING!** This function alters configuration of the serial port (without restoring it).

---

# Net Library

---

This chapter describes the API available in the net library and its Berkeley sockets equivalents. The header file `NetMgr.h` declares the net library API. The chapter covers:

- [Net Library Data Structures](#)
- [Net Library Constants](#)
- [Net Library Functions](#)

For more information on the net library, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

---

**IMPORTANT:** Applications cannot directly use the net library to make wireless connections. Use the `INetLib` for wireless connections.

---

## Net Library Data Structures

**New**

---

### NetConfigNameType

The `NetConfigNameType` structure defines a configuration name. A configuration is a specific set of values for the net library settings. Typically, users set up configurations and assign names to them using the Network preferences panel.

```
typedef struct {
    Char name[netConfigNameSize];
} NetConfigNameType, NetConfigNamePtr;
```

`name` is the configuration’s name. The `netConfigNameSize` constant is currently defined to be 32.

### Compatibility

Supported only if [3.2 New Feature Set](#) is present.

## NetHostInfoBufType

The `NetHostInfoBufType` struct contains information about a host. The [NetHostInfoType](#) struct, which maps to the `hostent` struct, points to fields in this struct for its information.

```
typedef struct {
    NetHostInfoType  hostInfo;
    Char             name [netDNSMaxDomainName+1];
    Char             *aliasList [netDNSMaxAliases+1];
    Char             aliases [netDNSMaxAliases
                             [netDNSMaxAliases+1];
    NetIPAddr       *addressList [netDNSMaxAddresses]
;
    NetIPAddr       address [netDNSMaxAddresses];
} NetHostInfoBufType, *NetHostInfoBufPtr;
```

### Field Descriptions

|                                                  |                                                                                                                   |
|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>hostInfo</code>                            | A <a href="#">NetHostInfoType</a> struct, which maps to the Berkeley UNIX sockets <code>hostent</code> structure. |
| <code>name</code>                                | Official host name.                                                                                               |
| <code>aliasList</code><br><code>aliases</code>   | An array of aliases for the host name.                                                                            |
| <code>addressList</code><br><code>address</code> | An array of pointers to 32-bit IP addresses in host byte order.                                                   |

## NetHostInfoType

The `NetHostInfoType` structure maps to the Berkeley UNIX sockets `hostent` structure. It is defined as follows:

```
typedef struct {
    Char             *nameP;
    Char             **nameAliasesP;
    UInt16          addrType;
    UInt16          addrLen;
```

```
        UInt8      **addrListP;  
    } NetHostInfoType, *NetHostInfoPtr;
```

### Field Descriptions

|              |                                                                           |
|--------------|---------------------------------------------------------------------------|
| nameP        | Official host name.                                                       |
| nameAliasesP | An array of aliases for the host name.                                    |
| addrType     | The type of the return addresses. See <a href="#">NetSocketAddrEnum</a> . |
| addrLen      | The length in bytes of the return addresses.                              |
| addrListP    | An array of pointers to addresses in host byte order.                     |

## NetServInfoBufType

The `NetServInfoBufType` struct contains information about a service. The [NetServInfoType](#) struct, which maps to the `servent` struct, points to fields in this struct for much of its information.

```
struct {
    NetServInfoType servInfo;
    Char            name [netServMaxName+1];
    Char            *aliasList [netServMaxAliases+1];
    Char            aliases [netServMaxAliases
[netServMaxName];
    Char            protoName [netProtoMaxName+1];
    UInt8          reserved;
} NetServInfoBufType, *NetServInfoBufPtr;
```

### Field Descriptions

|                                                |                                                                                                                   |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <code>servInfo</code>                          | A <a href="#">NetServInfoType</a> struct, which maps to the Berkeley UNIX sockets <code>servent</code> structure. |
| <code>name</code>                              | Official name of the service                                                                                      |
| <code>aliasList</code><br><code>aliases</code> | Array of aliases for the service name.                                                                            |
| <code>protoName</code>                         | Name of the protocol to use.                                                                                      |
| <code>reserved</code>                          | Reserved for future use.                                                                                          |

## NetServInfoType

The `NetServInfoType` structure maps to the `servent` structure in Berkeley UNIX sockets API. It contains information about a service.

```
struct {
    Char            *nameP;
    Char            **nameAliasesP;
    UInt16         port;
    Char            *protoP;
} NetServInfoType, *NetServInfoPtr;
```

### Field Descriptions

|                           |                                        |
|---------------------------|----------------------------------------|
| <code>nameP</code>        | Official name of the service           |
| <code>nameAliasesP</code> | Array of aliases for the service name. |
| <code>port</code>         | Port number for the service.           |
| <code>protoP</code>       | Name of the protocol to use.           |

### NetSocketAddrEnum

The `NetSocketAddrEnum` enum specifies the address types supported by the net library.

```
typedef enum {
    netSocketAddrRaw = 0,
    netSocketAddrINET = 2
} NetSocketAddrEnum
```

### Value Descriptions

|                                |                                                                        |
|--------------------------------|------------------------------------------------------------------------|
| <code>netSocketAddrRaw</code>  | Raw address. Supported in Palm OS <sup>®</sup> version 3.0 and higher. |
| <code>netSocketAddrINET</code> | IP address.                                                            |

### NetSocketAddrINType

The `NetSocketAddrINType` struct holds an internet socket address, that is, a socket that uses one of the internet protocols. This structure directly maps to the BSD UNIX `sockaddr_in` structure.

```
typedef struct NetSocketAddrINType {
    Int16      family;
    UInt16     port;
    NetIPAddr  addr;
} NetSocketAddrINType;
```

## Net Library

### Net Library Data Structures

---

#### Field Descriptions

`family` Address family in host byte order. This is either `netSocketAddrINET` or `netSocketAddrRaw`.

`port` The port in network byte order.

`addr` The IP address in network byte order.

### NetSocketAddrRawType

The `NetSocketAddrRawType` structure holds a raw socket address.

```
typedef struct NetSocketAddrRawType {
    Int16 family;
    UInt16 ifInstance;
    UInt32 ifCreator;
} NetSocketAddrRawType;
```

#### Field Descriptions

|                         |                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>family</code>     | Address family in host byte order. This is either <code>netSocketAddrINET</code> or <code>netSocketAddrRaw</code> . |
| <code>ifInstance</code> | The instance number of the interface that the socket uses to send and receive data.                                 |
| <code>ifCreator</code>  | The creator of the interface that the socket uses.                                                                  |

**Compatibility** Raw sockets are supported in Palm OS version 3.0 and higher.

## NetSocketAddrType

The `NetSocketAddrType` structure holds a generic socket address. This struct can hold any type of address including Internet addresses. It directly maps to the BSD UNIX `sockaddr` structure.

Note that this structure is the same size as `NetSocketAddrIntType` and `NetSocketAddrRawType`. This means that one of those two structures can be used for parameters declared to be `NetSocketAddrType`.

```
typedef struct NetSocketAddrType {
    Int16 family;
    UInt8 data[14];
} NetSocketAddrType;
```

## NetSocketRef

The `NetSocketRef` defines a socket descriptor. The socket descriptor is created and returned by [NetLibSocketOpen](#). It is used in any function that requires access to a socket.

```
typedef Int16 NetSocketRef
```

## NetSocketTypeEnum

The `NetSocketTypeEnum` enum specifies the available socket types.

```
typedef enum {
    netSocketTypeStream=1,
    netSocketTypeDatagram=2,
    netSocketTypeRaw=3,
    netSocketTypeReliableMsg=4
} NetSocketTypeEnum
```

### Value Descriptions

|                                    |                                 |
|------------------------------------|---------------------------------|
| <code>netSocketTypeStream</code>   | Streams protocol over wireline. |
| <code>netSocketTypeDatagram</code> | UDP protocol.                   |
| <code>netSocketTypeRaw</code>      | Raw mode.                       |

## Net Library Constants

---

### Configuration Aliases

A configuration is a set of specific values for the net library settings. The net library defines a set of built-in configuration aliases for common network setups. These aliases point to configurations instead of holding the actual values themselves. You can specify an alias anywhere in the API you would specify a configuration.

The constants listed here specify the alias names. Most of the net library API requires a configuration index rather than a name. Use [NetLibConfigIndexFromName](#) to obtain the alias's index from the name.

|                                    |                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------|
| <code>netCfgNameDefault</code>     | The default configuration.                                                                        |
| <code>netCfgNameDefWireline</code> | The default configuration for wireline communications.                                            |
| <code>netCfgNameDefWireless</code> | The default configuration for wireless communications.                                            |
| <code>netCfgNameCTPWireline</code> | The default configuration for wireline communications through the Palm Web Clipping Proxy server. |
| <code>netCfgNameCTPWireless</code> | The default configuration for wireless communications through the Palm Web Clipping Proxy server. |

By default, `netCfgNameDefault` points to the user's default configuration, and all other aliases point to `netCfgNameDefault` except for `netCfgNameCTPWireless`, which points to an private wireless configuration.

#### Compatibility

Supported on version 3.2 and later.

## I/O Flags

The I/O flags specify special handling instructions to functions that send and receive data. You can OR these values together to specify more than one.

|                                 |                                                                 |
|---------------------------------|-----------------------------------------------------------------|
| <code>netIOFlagOutOfBand</code> | Process out-of-band data. Available for send calls only.        |
| <code>netIOFlagPeek</code>      | Peek at incoming message without dequeuing it.                  |
| <code>netIOFlagDontRoute</code> | Send without using routing. This constant is currently ignored. |

## Tracing Bits

The tracing bits are used to set the level of event tracing. An application can get a list of events in the trace buffer using the [NetLibMaster](#) call.

You can set the tracing for each network interface using [NetLibIFSettingSet](#) and for the net library in general with [NetLibSettingSet](#).

|                                |                                                                                                                     |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>netTracingErrors</code>  | Record run-time errors. This is the default.                                                                        |
| <code>netTracingMsgs</code>    | Record application trace messages.                                                                                  |
| <code>netTracingPkts</code>    | Record packet I/O. This bit is obsolete in versions 3.2 and higher, but is mapped to <code>netTracingPktIP</code> . |
| <code>netTracingFuncs</code>   | Record function flow.                                                                                               |
| <code>netTracingAppMsgs</code> | Record application messages sent using <a href="#">NetLibTracePrintf</a> and <a href="#">NetLibTracePuts</a> .      |
| <code>netTracingPktIP</code>   | Record packet I/O. If this set, the following five options are enabled.                                             |

## Net Library

### Net Library Functions

---

|                               |                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>netTracingData40</code> | Record the first 40 bytes of each packet sent or received. This option is mutually exclusive with <code>netTracingData</code> . |
| <code>netTracingData</code>   | Record the entirety of each packet sent or received. This option is mutually exclusive with <code>netTracingData40</code> .     |
| <code>netTracingIFHi</code>   | Record packets sent or received at the highest layer of the network interface. This layer is just below the IP layer.           |
| <code>netTracingIFMid</code>  | Record packets sent or received at the layer just below the highest layer of the network interface.                             |
| <code>netTracingIFLow</code>  | Record packets sent or received at the lowest layer of the network interface.                                                   |

#### Compatibility

The `netTracingPktXXX` constants are supported only in version 3.2 devices and higher. In previous versions, specify `netTracingPkts` instead; only the size of the packet is recorded.

## Net Library Functions

### NetHToNL

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Purpose</b>     | Macro that converts a 32-bit value from host to network byte order. |
| <b>Declared In</b> | <code>NetBitUtils.h</code>                                          |
| <b>Prototype</b>   | <code>NetHToNL (x)</code>                                           |
| <b>Parameters</b>  | -> <code>x</code> 32-bit value to convert.                          |
| <b>Result</b>      | Returns <code>x</code> in network byte order.                       |

**Sockets Equivalent**    `htonl()`

**See Also**    [NetNToHS](#), [NetNToHL](#), [NetHToNS](#)

## NetHToNS

**Purpose**    Macro that converts a 16-bit value from host to network byte order.

**Declared In**    `NetBitUtils.h`

**Prototype**    `NetHToNS (x)`

**Parameters**    `-> x`                    16-bit value to convert.

**Result**    Returns `x` in network byte order.

**Sockets Equivalent**    `htons()`

**See Also**    [NetNToHS](#), [NetNToHL](#), [NetHToNL](#)

## NetLibAddrAToIN

**Purpose**    Converts an ASCII string representing a dotted decimal IP address into a 32-bit IP address in network byte order.

**Declared In**    `NetMgr.h`

**Prototype**    `NetIPAddr NetLibAddrAToIN (UInt16 libRefnum, const Char *a)`

**Parameters**    `-> libRefNum`            Reference number of the net library.  
                  `-> a`                    Pointer to ASCII dotted decimal string.

**Result**    Returns a 32-bit network byte order IP address or -1 if `a` doesn't represent a dotted decimal IP address

## Net Library

### Net Library Functions

---

**Sockets Equivalent**    `UInt32 inet_addr (char *cp)`

**See Also**    [NetLibAddrINToA](#)

## NetLibAddrINToA

**Purpose**    Converts an IP address from 32-bit network byte order into a dotted decimal ASCII string.

**Declared In**    `NetMgr.h`

**Prototype**    `Char *NetLibAddrINToA (UInt16 libRefnum,  
NetIPAddr inet, Char *spaceP)`

**Parameters**

- > `libRefNum`    Reference number of the net library.
- > `inet`    32-bit IP address in network byte order.
- <- `spaceP`    Buffer used to hold the return value.

**Result**    Returns in `spaceP` the dotted decimal ASCII string representation of the IP address.

**Sockets Equivalent**    `char *inet_ntoa (struct in_addr in)`

**See Also**    [NetLibAddrAToIN](#)

## NetLibClose

**Purpose**    Closes the net library.

**Declared In**    `NetMgr.h`

**Prototype**    `Err NetLibClose (UInt16 libRefnum,  
UInt16 immediate)`

**Parameters**    -> `libRefnum`    Reference number of the net library.

-> `immediate` If `true`, library will shut down immediately. If `false`, library will shut down only if close timer expires before another [NetLibOpen](#) is issued.

**Result** Returns one of the following values:

`0` Success.

`netErrNotOpen` Library was not open.

`netErrStillOpen`

Not really an error; returned if library is still in use by another application.

**Sockets Equivalent** None.

**Comments** Applications must call this function when they no longer need the net library. If the net library open count is greater than 1 before this call is made, the count is decremented and `netErrStillOpen` is returned. If the open count was 1, the library takes the following action:

- If `immediate` is `true`, the library shuts down immediately. All network interfaces are brought down, the net protocol stack task is terminated, and all memory used by the net library is freed.
- If `immediate` is `false`, a close timer is created and this call returns immediately without actually bringing the net library down. Instead it leaves it up and running but marks it as in the "close-wait" state. It remains in this state until either the timer expires or another `NetLibOpen` is issued. If the timer expires, the library is shut down. If another `NetLibOpen` call is issued before the timer expires (possibly by another application), the timer is cancelled and the library is marked as fully open.

In most cases, you should pass `false` for `immediate`. This allows the user to quit one Internet application and launch another within

## Net Library

### Net Library Functions

---

a short period of time without having to wait through the process of closing down and then re-establishing dial-up network connections.

**See Also** [NetLibOpen](#), [NetLibOpenCount](#)

---

## **New** NetLibConfigAliasGet

**Purpose** Return the configuration that an alias points to.

**Prototype** `Err NetLibConfigAliasGet (UInt16 refNum,  
UInt16 aliasIndex, UInt16 *indexP,  
Boolean *isAnotherAliasP)`

**Parameters**

- > refNum Reference number of the net library.
- > aliasIndex Index of the alias.
- <- indexP Index of the configuration pointed to by the alias.
- <- isAnotherAliasP  
true if indexP is the index of another alias;  
false if indexP specifies an actual  
configuration.

**Result** Returns one of the following values:

0 Success.

netErrConfigNotAlias  
The configuration at aliasIndex is not an  
alias.

netErrOutOfCmdBlocks

netErrParamErr The specified index is out of range or there is no  
configuration at the index.

**Sockets  
Equivalent** None

**Comments** Use this routine to find out which configuration a built-in alias points to. See "[Configuration Aliases](#)" for a description of the built-in aliases.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

**See Also** [NetLibConfigAliasSet](#)

---

## **New** **NetLibConfigAliasSet**

**Purpose** Set a built-in alias to point to a defined configuration.

**Prototype** Err NetLibConfigAliasSet (UInt16 refNum, UInt16 configIndex, UInt16 aliasToIndex)

**Parameters**

- > refNum Reference number of the net library.
- > configIndex Index of the built-in alias to be set.
- > aliasToIndex Index of the configuration to which the alias should point. You cannot set an alias to point to itself.

**Result** Returns one of the following values:

0 Success.

netErrConfigCantPointToAlias

The configuration at aliasToIndex is an alias that points to an alias.

netErrConfigNotAlias

The configuration at configIndex isn't an alias.

netErrOutOfCmdBlocks

netErrParamErr The specified index is out of range or there's no configuration at the index.

## Net Library

### Net Library Functions

---

**Sockets Equivalent** None

**Comments** This function is used by the Network preferences panel when the user edits a configuration. Your application can use it to associate any of the built-in aliases with a defined configuration.

The built-in aliases are typically set up as shown in [Table 61.1](#). In this example, applications that specify a configuration index of 0 through 3 use a configuration that the user defines. Applications that use index 4 use a private configuration created by the network library.

**Table 61.1 Example Configuration Table**

| Index | Name         | Alias To |
|-------|--------------|----------|
| 0     | .Default     | 6        |
| 1     | .DefWireline | 0        |
| 2     | .DefWireless | 0        |
| 3     | .CTPWireline | 0        |
| 4     | .CTPWireless | 5        |
| 5     | _RAMCTP      |          |
| 6     | user-defined |          |

An alias can point to another alias so long as the nesting level is only one deep. That is, if you point an alias to an alias, you'll receive an error if that alias in turn points to another alias. This eliminates the possibility that an alias never resolves to an actual configuration.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

**See Also** [NetLibConfigAliasGet](#)

---

## **New** **NetLibConfigDelete**

**Purpose** Delete a configuration from the net library's configuration table.

**Prototype** `Err NetLibConfigDelete (UInt16 refNum,  
UInt16 index)`

**Parameters**

|           |                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| -> refNum | Reference number of the net library.                                                                                                        |
| -> index  | Index of the configuration to delete. You cannot delete one of the built-in aliases described in " <a href="#">Configuration Aliases</a> ." |

**Result** Returns one of the following values:

0 Success.

netErrConfigCantDelete

The configuration at index is a built-in alias.

netErrOutOfCmdBlocks

netErrParamErr The specified index is out of range.

**Sockets  
Equivalent** None

**Compatibility** Implemented only if [3.2 New Feature Set](#) Set is present.

**See Also** [NetLibConfigSaveAs](#)

---

## **NetLibConfigIndexFromName**

**Purpose** Obtain a configuration's index given its name.

**Prototype** `Err NetLibConfigIndexFromName (UInt16 refNum, NetConfigNamePtr nameP, UInt16 *indexP)`

**Parameters**

|           |                                                                          |
|-----------|--------------------------------------------------------------------------|
| -> refNum | Reference number of the net library.                                     |
| -> nameP  | Pointer to a configuration name. See <a href="#">NetConfigNameType</a> . |
| <- indexP | The index of the configuration with the name *nameP.                     |

**Result** Returns one of the following values:

|                      |                                                             |
|----------------------|-------------------------------------------------------------|
| 0                    | Success.                                                    |

**Sockets Equivalent** None

**Comments** This function returns the index of a configuration given its name. Your application should store the configuration's index rather than its name because a configuration's name can change.

If you pass the name of a built-in alias in nameP, this function returns the index of the alias's entry in the configuration table; it does not return the index that the alias points to. For example, if the alias netCfgNameCTPWireless is stored at index 4 and points to index 5, NetLibConfigIndexFromName returns 4. If you want to obtain the index that an alias points to, use [NetLibConfigAliasGet](#).

**Compatibility**    Implemented only if [3.2 New Feature Set](#) is present.

**See Also**        [NetLibConfigList](#)

---

## **New**    **NetLibConfigList**

**Purpose**          Return a list of net library configuration names.

**Prototype**       `Err NetLibConfigList (UInt16 refNum,  
NetConfigNameType nameArray[],  
UInt16 *arrayEntriesP)`

**Parameters**     `-> refNum`            Reference number of the net library.  
`<- nameArray`        The list of defined configurations. See [NetConfigNameType](#).  
`<-> arrayEntriesP`  
                          On entry, contains the number of elements in nameArray. On return, contains the number of elements in nameArray that were actually used. The Net Library currently returns up to 16 entries. If the array is not large enough to hold all the configuration names, this function returns only as many names as the array can hold.

**Result**          Returns one of the following values:

0                    Success.  
`netErrOutOfCmdBlocks`

**Sockets  
Equivalent**      None

**Comments**       Use this function to obtain a list of the names of defined network configurations and configuration aliases.

## Net Library

### Net Library Functions

---

Users create specific configurations using the Network preferences panel and associate names with each configuration. This function returns the list of defined configurations.

In addition to user-defined configurations, this function also returns built-in configuration aliases and private configurations. The built-in configuration aliases are described in "[Configuration Aliases](#)." Their actual names begin with a period (.). Private configurations have names that begin with an underscore (\_).

---

**IMPORTANT:** If you present the list returned by this function to your application's users, you must first filter out names beginning with a period or an underscore. These names are for internal use only.

---

Your application should refer to a configuration by its index rather than its name because the name can be changed. To obtain the configuration's index from its name, use [NetLibConfigIndexFromName](#).

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

---

## **New** NetLibConfigMakeActive

**Purpose** Makes the specified configuration current without opening the net library.

**Prototype** `Err NetLibConfigMakeActive (UInt16 refNum, UInt16 configIndex)`

**Parameters**

- > `refNum` Reference number of the net library.
- > `configIndex` Index of the configuration to use. An index of 0 refers to the default configuration as defined by the Network preferences panel.

**Result** Returns one of the following values:

0 Success.

netErrBufTooSmall  
netErrConfigAliasErr  
netErrConfigCantDelete  
netErrConfigEmpty  
netErrConfigNotFound  
netErrOutOfCmdBlocks  
netErrParamErr  
netErrPrefNotFound

**Sockets  
Equivalent**

None

**Comments**

This function is used mainly by the Network preferences panel when the user edits and saves network configurations. The Network preferences panel uses this function to make current the configuration the user wants to edit, set the settings appropriately, and then save the configuration using [NetLibConfigSaveAs](#).

Use this routine to make a specific configuration the current configuration without opening the net library. You should not use it if the net library is already open.

Unlike [NetLibOpenConfig](#), this routine does not save the current net library configuration so that it can be restored upon close.

**Compatibility**

Implemented only if [3.2 New Feature Set](#) is present.

  
**New**

---

## **NetLibConfigRename**

**Purpose** Rename the specified configuration.

**Prototype** `Err NetLibConfigRename (UInt16 refNum,  
UInt16 index, NetConfigNamePtr newNameP)`

**Parameters**

- > `refNum` Reference number of the net library.
- > `configIndex` Index of the configuration to be renamed.
- > `newNameP` Pointer to the new name. See [NetConfigNameType](#). The new name must not start with a period (.) or an underscore (\_).

**Result** Returns one of the following values:

0 Success.

`netErrConfigBadName`  
The new name begins with a period.

`netErrConfigCantDelete`  
The configuration at the specified index is a built-in alias or private configuration that cannot be renamed.

`netErrOutOfCmdBlocks`

`netErrParamErr` The specified index is out of range or there is no configuration at the index.

**Sockets  
Equivalent** None

**Comments** You cannot specify a name beginning with a period (.) or an underscore (\_). Names beginning with a period are reserved for the built-in configuration aliases. Names beginning with an underscore are hidden configurations used internally by net library.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

| 0                         | Success.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |           |                                      |                     |                                                                                                                                                  |                     |                                                                                                 |                      |  |
| netErrConfigBadName       | The specified name begins with a period or underscore.                                                                                                                                                                                                                                                                                                                                                                                                                                                             |           |                                      |                     |                                                                                                                                                  |                     |                                                                                                 |                      |  |
| netErrConfigTooMany       | Not enough space to add another configuration. The Net Library can hold up to 16 configuration.                                                                                                                                                                                                                                                                                                                                                                                                                    |           |                                      |                     |                                                                                                                                                  |                     |                                                                                                 |                      |  |
| netErrOutOfCmdBlocks      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |           |                                      |                     |                                                                                                                                                  |                     |                                                                                                 |                      |  |
| <b>Sockets Equivalent</b> | None                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |           |                                      |                     |                                                                                                                                                  |                     |                                                                                                 |                      |  |
| <b>Comments</b>           | <p>If the name you specify already exists, its configuration is replaced with this configuration.</p> <p>You cannot specify a name beginning with a period (.) or an underscore (_). Names beginning with a period are reserved for the built-in configuration aliases. Names beginning with an underscore are hidden configurations used internally by net library.</p> <p>The net library assigns an index to this new configuration. The configuration's index remains constant, while its name may change.</p> |           |                                      |                     |                                                                                                                                                  |                     |                                                                                                 |                      |  |

## Net Library

### Net Library Functions

---

Use [NetLibConfigIndexFromName](#) to obtain the configuration's index.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

**See Also** [NetLibConfigDelete](#), [NetLibConfigRename](#)

## NetLibConnectionRefresh

**Purpose** This routine is a convenience call for applications. It checks the status of all connections and optionally tries to open any that were closed.

**Declared In** NetMgr.h

**Prototype** Err NetLibConnectionRefresh (UInt16 refNum,  
Boolean refresh, UInt8 \*allInterfacesUpP,  
UInt16 \*netIFErrP)

**Parameters**

- > refnum Reference number of the net library.
- > refresh If true, any connections that aren't currently open are opened.
- <- allInterfacesUpP Set to true if all connections are open.
- <- netIFErrP First error encountered when reopening connections that were closed. (See [NetLibIFUp](#) for a list of possible values.)

**Result** Returns one of the following values:

- 0 Success.
- netErrBufTooSmall
- netErrOutOfCmdBlocks
- netErrNoInterfaces

**Sockets Equivalent** None.

**Comments** This function determines whether a connection is up based on the internal status of the TCP/IP stack. To test the presence of a “physical connection” (phone line, modem, serial cable), a command should be sent once it’s been determined that the logical connection is up. If the physical connection is broken, nothing returns and a timeout error eventually occurs.

## NetLibDmReceive

**Purpose** Receive data from a socket directly into a database record.

**Declared In** NetMgr.h

**Prototype** `Int16 NetLibDmReceive (UInt16 libRefNum, NetSocketRef socket, void *recordP, UInt32 recordOffset, UInt16 rcvLen, UInt16 flags, void *fromAddrP, UInt16 *fromLenP, Int32 timeout, Err *errP)`

**Parameters**

|                 |                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| -> libRefNum    | Reference number of the net library.                                                                                                       |
| -> socket       | Descriptor for the open socket.                                                                                                            |
| <- recordP      | Pointer to beginning of record to receive data into. Must be locked for use.                                                               |
| -> recordOffset | Offset from beginning of record to read data into.                                                                                         |
| -> rcvLen       | Maximum number of bytes to read.                                                                                                           |
| -> flags        | One or more netIOFlagxxx flags. See “ <a href="#">I/O Flags</a> .”                                                                         |
| <- fromAddrP    | Pointer to buffer to hold address of sender (a <a href="#">NetSocketAddrType</a> struct). Pass NULL if you don’t need sender information.  |
| <-> fromLenP    | On entry, size of fromAddrP buffer. On exit, actual size of returned address in fromAddrP. Pass NULL if you don’t need sender information. |

## Net Library

### Net Library Functions

---

-> timeout           Maximum timeout in system ticks; -1 means wait forever.

<- errP               Contains an error code if the return value is -1.

**Result**           Returns the number of bytes successfully received. If the return value is 0, the socket has been shut down by the remote host. If the return value is -1, an error has occurred and errP contains one of the following values:

0                     No error.

netErrTimeout        Call timed out.

netErrNotOpen        The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrWouldBlock

netErrUserCancel

netErrOutOfMemory

**Comments**        This call behaves similarly to [NetLibReceive](#) but reads the data directly into a database record, which is normally write-protected. The caller must pass a pointer to the start of the record and an offset into the record of where to start the read.

## NetLibFinishCloseWait

**Purpose**           Forces the net library to do a complete close if it's currently in the close-wait state.

**Declared In**     NetMgr.h

**Prototype**       Err NetLibFinishCloseWait (UInt16 libRefnum)

**Parameters**     -> libRefnum       Reference number of the net library.

**Result**           Returns one of the following values:

0 Success.

netErrTimeout

**Sockets  
Equivalent**

None.

**Comments** This call checks the current open state of the net library. If it's in the close-wait state (see [NetLibClose](#)), it forces the library to perform an immediate, complete close operation.

## NetLibGetHostByAddr

**Purpose** Looks up a host name given its IP address.

**Declared In** NetMgr.h

**Prototype** NetHostInfoPtr NetLibGetHostByAddr  
(UInt16 libRefNum, UInt8 \*addrP, UInt16 len,  
UInt16 type, NetHostInfoBufPtr bufP,  
Int32 timeout, Err \*errP)

**Parameters**

|              |                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------|
| -> libRefNum | Reference number of the net library.                                                                |
| -> addrP     | IP address of host to lookup.                                                                       |
| -> len       | Length, in bytes, of *addrP.                                                                        |
| -> type      | Type of addrP. See <a href="#">NetSocketAddrEnum</a> .                                              |
| <- bufP      | Pointer to a <a href="#">NetHostInfoBufType</a> struct in which to store the results of the lookup. |
| -> timeout   | Maximum timeout in system ticks; -1 means wait forever.                                             |
| <- errP      | Contains an error code if the return value is 0.                                                    |

**Result** Returns a pointer to the [NetHostInfoType](#) portion of bufP that contains results of the lookup. If the return value is 0, an error has occurred, and errP contains one of the following values:

0 No error

## Net Library

**Sockets Equivalent** struct hostent \*gethostbyaddr (char \*addr, int len, int type);

**Comments** This call queries the domain name server(s) to look up a host name given its IP address.

**See Also** [NetLibGetHostByName](#)

## NetLibGetHostByName

- Purpose** Looks up a host IP address given a host name.
- Declared In** `NetMgr.h`
- Prototype**  
`NetHostInfoPtr NetLibGetHostByName  
(UInt16 libRefNum, const Char *nameP,  
NetHostInfoBufPtr bufP, Int32 timeout, Err *errP)`
- Parameters**
- |                              |                                                                                                     |
|------------------------------|-----------------------------------------------------------------------------------------------------|
| <code>-&gt; libRefNum</code> | Reference number of the net library.                                                                |
| <code>-&gt; nameP</code>     | Name of host to look up.                                                                            |
| <code>&lt;- bufP</code>      | Pointer to a <a href="#">NetHostInfoBufType</a> struct in which to store the results of the lookup. |
| <code>-&gt; timeout</code>   | Maximum timeout in system ticks; -1 means wait forever.                                             |
| <code>&lt;- errP</code>      | Contains an error code if the return value is 0.                                                    |
- Result** Returns a pointer to the [NetHostInfoType](#) portion of `bufP`, which contains results of the lookup. If the return value is 0, an error has occurred and `errP` contains one of the following values:
- |                                         |                                                     |
|-----------------------------------------|-----------------------------------------------------|
| 0                                       | No error                                            |
| <code>netErrTimeout</code>              | Call timed out.                                     |
| <code>netErrNotOpen</code>              | The referenced net library has not been opened yet. |
| <code>netErrDNSNameTooLong</code>       |                                                     |
| <code>netErrDNSBadName</code>           |                                                     |
| <code>netErrDNSLabelTooLong</code>      |                                                     |
| <code>netErrDNSAllocationFailure</code> |                                                     |
| <code>netErrDNSTimeout</code>           |                                                     |
| <code>netErrDNSUnreachable</code>       |                                                     |
| <code>netErrDNSFormat</code>            |                                                     |
| <code>netErrDNSServerFailure</code>     |                                                     |

## Net Library

### Net Library Functions

---

```
netErrDNSNonexistantName
netErrDNSNIY
netErrDNSRefused
netErrDNSImpossible
netErrDNSNoRRS
netErrDNSAborted
netErrDNSBadProtocol
netErrDNSTruncated
netErrDNSNoRecursion
netErrDNSIrrelevant
netErrDNSNotInLocalCache
netErrDNSNoPort
```

#### **Sockets Equivalent**

```
struct hostent *gethostbyname (char *name);
```

#### **Comments**

This call first checks the local name -> IP address host table in the net library preferences. If the entry is not found, it then queries the domain name server(s).

#### **See Also**

[NetLibGetHostByAddr](#), [NetLibGetMailExchangeByName](#)

## NetLibGetMailExchangeByName

#### **Purpose**

Looks up the name of a host to use for a given mail exchange.

#### **Declared In**

NetMgr.h

#### **Prototype**

```
Int16 NetLibGetMailExchangeByName
(UInt16 libRefNum, Char *mailNameP,
UInt16 maxEntries, Char hostNames[][255+1],
UInt16 priorities[], Int32 timeout, Err *errP)
```

#### **Parameters**

-> libRefNum      Reference number of the net library.

|               |                                                                                                                                                             |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> mailNameP  | Name of the mail exchange to look up.                                                                                                                       |
| -> maxEntries | Maximum number of host names to return.                                                                                                                     |
| <- hostNames  | Array of character strings of length 255+1. The host name results are stored in this array. This array must be able to hold at least maxEntries host names. |
| <- priorities | Array of Words. The priorities of each host name found are stored in this array. This array must be at least maxEntries in length.                          |
| -> timeout    | Maximum timeout in system ticks; -1 means wait forever.                                                                                                     |
| <- errP       | Contains an error code if the return value is less than 0.                                                                                                  |

**Result** Returns the number of entries successfully found. If the return value is a negative number, an error has occurred, and errP contains one of the following values:

|                            |                                                     |
|----------------------------|-----------------------------------------------------|
| 0                          | No error                                            |
| netErrTimeout              | Call timed out.                                     |
| netErrNotOpen              | The referenced net library has not been opened yet. |
| netErrDNSNameTooLong       |                                                     |
| netErrDNSBadName           |                                                     |
| netErrDNSLabelTooLong      |                                                     |
| netErrDNSAllocationFailure |                                                     |
| netErrDNSTimeout           |                                                     |
| netErrDNSUnreachable       |                                                     |
| netErrDNSFormat            |                                                     |
| netErrDNSServerFailure     |                                                     |
| netErrDNSNonexistentName   |                                                     |
| netErrDNSNIY               |                                                     |
| netErrDNSRefused           |                                                     |

## Net Library

### Net Library Functions

---

netErrDNSImpossible  
netErrDNSNoRRS  
netErrDNSAborted  
netErrDNSBadProtocol  
netErrDNSTruncated  
netErrDNSNoRecursion  
netErrDNSIrrelevant  
netErrDNSNotInLocalCache  
netErrDNSNoPort

**Sockets  
Equivalent**

None

**Comments**

This call looks up the name(s) of host(s) to use for sending an e-mail. The caller passes the name of the mail exchange in mailNameP and gets back a list of host names to which the mail message can be sent.

**See Also**

[NetLibGetHostByAddr](#), [NetLibGetHostByName](#)

## NetLibGetServByName

**Purpose**

Looks up the port number for a standard TCP/IP service, given the desired protocol.

**Declared In**

NetMgr.h

**Prototype**

```
NetServInfoPtr NetLibGetServByName  
(UInt16 libRefNum, const Char *servNameP,  
const Char *protoNameP, NetServInfoBufPtr bufP,  
Int32 timeout, Err *errP)
```

**Parameters**

-> libRefNum      Reference number of the net library.

-> servNameP      Name of the service to look up. Possible services are "echo", "discard", "daytime", "qotd", "chargen", "ftp-data", "ftp", "telnet", "smtp", "time", "name", "finger", "pop2", "pop3", "nntp", "imap2".

-> protoNameP      Desired protocol to use, either "udp" or "tcp".

<- bufP            Pointer to a [NetServInfoBufType](#) struct in which to store the results of the lookup.

-> timeout          Maximum timeout in system ticks; -1 means wait forever.

<- errP            Contains an error code if the return value is 0.

**Result**          Returns a pointer to the [NetServInfoType](#) portion of bufP that contains results of the lookup. If the return value is 0, and error has occurred and errP contains one of the following values:

0                    No error

netErrTimeout      Call timed out.

netErrNotOpen      The referenced net library has not been opened yet.

netErrUnknownProtocol

netErrUnknownService

**Sockets Equivalent**      struct servent \*getservbyname (char \*addr, char \*proto);

**Comments**            This call is a convenience call for looking up a standard port number given the name of a service and the protocol to use.

**See Also**            [NetLibGetHostByName](#)

| <b>Comments</b>           | <p>This call can be used to attach a new network interface to the net library. Network interfaces are self-contained databases of type 'neti'. The ifCreator parameter to this function is used to locate the network interface database of the given creator.</p> <p>If the net library is already open when this call is made, the network interface's database will be located and then called to initialize itself and attach itself to the protocol stack in real time. If the net library is not open when this call is made, the creator and instance number of the interface are stored in the active configuration. You need to save the active configuration using <a href="#">NetLibConfigSaveAs</a> if you want</p> |              |                                      |              |                                 |               |                                                                                                                            |            |                                              |

the interface to be initialized and attached to the stack the next time the net library is opened.

## NetLibIFDetach

**Purpose** Detach a network interface from the protocol stack.

**Declared In** NetMgr.h

**Prototype** Err NetLibIFDetach (UInt16 libRefNum,  
UInt32 ifCreator, UInt16 ifInstance,  
Int32 timeout)

**Parameters**

- > libRefNum      Reference number of the net library.
- > ifCreator      Creator of interface to detach.
- > ifInstance     Instance number of interface to detach.
- > timeout        Timeout in ticks; -1 means infinite timeout.

**Result** Returns one of the following values:

0                    Success.  
netErrInterfaceNotFound

**Sockets  
Equivalent**      None

**Comments** If the net library is already open when this call is made, the interface is brought down and detached from the protocol stack in real time. If the net library is not open when this call is made, the creator and instance number of the interface are removed from the active configuration. You need to save the active configuration using [NetLibConfigSaveAs](#) if you don't want the interface to be attached the next time the library is opened.

| <b>Parameters</b>         | -> libRefNum      Reference number of the net library.<br>-> index            Index of the interface to get. Indices start at 0.<br><- ifCreatorP      The interface's creator.<br><- ifInstanceP     The interface's instance number.                                                                                                                             |
| <b>Result</b>             | Returns one of the following values:<br>0                    Success.<br>netErrInvalidInterface      Index too high<br>netErrPrefNotFound          No current value for setting.                                                                                                                                                                                   |
| <b>Sockets Equivalent</b> | None                                                                                                                                                                                                                                                                                                                                                               |
| <b>Comments</b>           | To get a list of all installed interfaces, call this function with successively increasing indices starting from 0 until the error netErrInvalidInterface is returned.<br><br>The ifCreator and ifInstance values returned from this call can then be used with the <a href="#">NetLibSettingGet</a> call to get more information about that particular interface. |

**Comments** This call can be used to retrieve the current value of any network interface setting. The caller must pass a pointer to a buffer to hold the return value (`valueP`), the size of the buffer (`*valueLenP`), and the setting ID (`setting`). The setting ID is one of the constants in the `NetIFSettingEnum` type.

Some settings, such as the login script, are variable size. For these types of settings, you can obtain the actual size required for the buffer by passing 0 for `*valueLenP`. The required size is returned in `valueLenP`.

[Table 61.2](#) lists the network interface settings and the size of each setting. Some are only applicable to certain types of interfaces. Settings not applicable to a specific interface can be safely ignored and not set to any particular value.

**Table 61.2 Network Interface Settings**

| <b>netIFSetting...</b> | <b>Type</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                               |
|------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ResetAll               | void        | Use with <a href="#">NetLibIFSettingSet</a> only. This clears all other settings for the interface to their default values.                                                                                                                                                                                                      |
| Up                     | UInt8       | Read-only. true if interface is currently up.                                                                                                                                                                                                                                                                                    |
| Name                   | Char [32]   | Read-only. Name of this interface.                                                                                                                                                                                                                                                                                               |
| ReqIPAddr              | UInt32      | IP address of interface.                                                                                                                                                                                                                                                                                                         |
| SubnetMask             | UInt32      | Subnet mask for interface. Doesn't need to be specified for PPP or SLIP type connections.                                                                                                                                                                                                                                        |
| Broadcast              | UInt32      | Broadcast address for interface. Doesn't need to be specified for PPP or SLIP type connections.                                                                                                                                                                                                                                  |
| Username               | Char [32]   | User name. Only required if the login script uses the user name substitution escape sequence in it. Call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0 to remove this setting.                                                                                                                                         |
| Password               | Char [32]   | Password. Only required if the login script uses the password substitution escape sequence in it. Call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0 to remove this setting. If the login script uses password substitution and no password setting is set, the user will be prompted for a password at connect time.  |
| AuthUsername           | Char [32]   | Authentication user name. Only required if the authentication protocol uses a different user name than the what's in the netIFSettingUsername setting. If this setting is empty (valueLen of 0), the Username setting will be used instead. Call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0 to remove this setting. |

**Table 61.2 Network Interface Settings (*continued*)**

| <b>netIFSetting...</b>   | <b>Type</b> | <b>Description</b>                                                                                                                                                                                                                                                                                               |
|--------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AuthPassword             | Char [32]   | Authentication password. If "\$" then the user will be prompted for the authentication password at connect time. Else, if 0 length, then the netIFSettingPassword setting or the result of its prompt will be used instead. Call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0 to remove this setting. |
| ServiceName              | Char []     | Service name. Used for display purposes while showing the connection progress dialog box. Call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0 to remove this setting.                                                                                                                                   |
| LoginScript              | Char []     | Login script. Only required if the particular service requires a login sequence. Call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0 to remove this setting. See below for a description of the login script format.                                                                                    |
| ConnectLog               | Char []     | Connect log. Generally, this setting is just retrieved, not set. It contains a log of events from the most recent login. To clear this setting, call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0.                                                                                                    |
| InactivityTimeout        | UInt16      | Maximum number of seconds of inactivity allowed. Set to 0 to ignore.                                                                                                                                                                                                                                             |
| EstablishmentTime<br>out | UInt16      | Maximum delay, in seconds, allowed between each stage of connection establishment or login script line. Must be non-zero.                                                                                                                                                                                        |
| DynamicIP                | UInt8       | If non-zero, negotiate for an IP address. If zero, the IP address specified in the netIFSettingReqIPAddr setting will be used. Default is false.                                                                                                                                                                 |
| VJCompEnable             | UInt8       | If non-zero, enable VJ header compression. Default is true for PPP, false for SLIP, and true for CSLIP.                                                                                                                                                                                                          |

**Table 61.2 Network Interface Settings (*continued*)**

| <b>netIFSetting...</b> | <b>Type</b> | <b>Description</b>                                                                                                                                                        |
|------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VJCompSlots            | UInt8       | Number of slots to use for VJ compression. Default is 4 for PPP and 16 for SLIP and CSLIP. More slots require more memory so it is best to keep this number to a minimum. |
| MTU                    | UInt16      | Maximum transmission unit in octets. Currently not implemented in SLIP or PPP.                                                                                            |
| AsyncCtlMap            | UInt32      | Bit mask of characters to escape for PPP. Default is 0.                                                                                                                   |
| PortNum                | UInt16      | Which serial communication port to use. Port 0 is the only port available on the device.                                                                                  |
| BaudRate               | UInt32      | Serial port baud rate to use in bits per second.                                                                                                                          |
| FlowControl            | UInt8       | If bit 0 is 1, use hardware handshaking on the serial port. Default is no hardware handshaking.                                                                           |
| StopBits               | UInt8       | Number of stop bits. Default is 1.                                                                                                                                        |
| ParityOn               | UInt8       | true if parity detection enabled. Default is false.                                                                                                                       |
| ParityEven             | UInt8       | true for even parity detection. Default is true.                                                                                                                          |
| UseModem               | UInt8       | If true, dial-up through modem. If false, go direct over serial port                                                                                                      |
| PulseDial              | UInt8       | If true, pulse dial modem. Else, tone dial. Default is tone dial.                                                                                                         |
| ModemInit              | Char []     | Zero-terminated modem initialization string, not including the "AT". If not specified (valueLen of 0), the modem initialization string from system preferences are used.  |
| ModemPhone             | Char []     | Zero-terminated modem phone number string. Only required if netIFSettingUseModem is true.                                                                                 |

**Table 61.2 Network Interface Settings (*continued*)**

| <b>netIFSetting...</b> | <b>Type</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                     |
|------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RedialCount            | UInt16      | Number of times to re-dial modem when trying to establish a connection. Only required if netIFSettingUseModem is true.                                                                                                                                                                                                 |
| DNSQuery               | UInt8       | true if PPP queries for DNS address. The default is true.                                                                                                                                                                                                                                                              |
| TraceBits              | UInt32      | A bitfield of various trace bits. See " <a href="#">Tracing Bits</a> ." An application can get a list of events in the trace buffer using the <a href="#">NetLibMaster</a> call. Each interface has its own trace bits setting so that trace event recording in each interface can be selectively enabled or disabled. |
| ActualIPAddr           | UInt32      | Read-only. The actual IP address that the interface ends up using. The login script execution engine stores the result of the "g" (get IP address) command here as does the PPP negotiation logic.                                                                                                                     |
| ServerIPAddr           | UInt32      | Read-only. The IP address of the PPP server we're connected to.                                                                                                                                                                                                                                                        |
| BringDownOnPowerDown   | UInt8       | true if the interface is brought down when the Palm OS device is turned off.                                                                                                                                                                                                                                           |
| RawMode                | UInt32      | Specifies if the interface is in raw mode. The net library places an interface in raw mode when it is bound to a raw socket in the raw domain. Raw sockets are available in Palm OS version 3.0 and higher.                                                                                                            |
| DriverVersion          | Char[20]    | Read-only. The version number of the network interface device driver. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                                                                                                                                  |
| FirmwareVersion        | Char[20]    | Read-only. The firmware version of the network interface device, if any. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                                                                                                                               |

**Table 61.2 Network Interface Settings (continued)**

| <b>netIFSetting...</b> | <b>Type</b> | <b>Description</b>                                                                                                                                                                                                                            |
|------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FirmwareDate           | UInt32      | Read-only. Firmware date in seconds since midnight, January 1, 1904. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                                                          |
| 80211Device            | UInt8       | Read-only. Indicates whether or not the interface supports IEEE 802.11 wireless networking. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                                   |
| 80211ESSID             | Char[32]    | For IEEE 802.11 interfaces only. The ESS ID of the radio. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                                                                     |
| 80211AccessPointBSSID  | UInt8[6]    | Read-only. For IEEE 802.11 interfaces only. The BSS ID (MAC address) of the access point to which the radio is connected. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                     |
| 80211AssociationStatus | UInt8       | Read-only. For IEEE 802.11 interfaces only. <code>true</code> if the radio is associated. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                                     |
| 80211MKKCallSign       | Char[15]    | Read-only. For IEEE 802.11 interfaces with radios programmed for operation in Japan only. The MKK call sign. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present.                                                  |
| 80211CountryText       | Char[34]    | Read-only. For IEEE 802.11 interfaces only. The radio's country code, which the radio uses to check if it operates within a particular country's regulations. This setting is defined only if <a href="#">5.1 New Feature Set</a> is present. |

| <b>Comments</b>           | This call can be used to set the current value of any network interface setting. The caller must pass a pointer to a buffer which                                                                                                                                                                                                                                                                                                                                                                                             |              |                                      |                      |                                   |                    |                                           |                     |                                                                                             |                         |                             |                    |                      |                       |  |

## Net Library

### Net Library Functions

---

holds the new value (`valueP`), the size of the buffer (`valueLen`), and the setting ID (`setting`).

See [NetLibIFSettingGet](#) for an explanation of each of the settings.

Of particular interest is the `netIFSettingResetAll` setting, which, if used, resets all settings for the interface to their default values. When using this setting, `valueP` and `valueLen` are ignored.

**See Also** [NetLibIFSettingGet](#), [NetLibSettingGet](#), [NetLibSettingSet](#), “[Interface Specific Settings](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*

## NetLibIFUp

**Purpose** Bring an interface up and establish a connection.

**Declared In** `NetMgr.h`

**Prototype** `Err NetLibIFUp (UInt16 libRefNum, UInt32 ifCreator, UInt16 ifInstance)`

**Parameters**

- > `libRefNum` Reference number of the net library.
- > `ifCreator` Creator of interface to attach.
- > `ifInstance` Instance number of interface to attach.

**Result** Returns one of the following values:

- 0 Success.
- `netErrNotOpen` The referenced net library has not been opened yet.
- `netErrInterfaceNotFound`
- `netErrUserCancel`
- `netErrBadScript`
- `netErrPPPTimeout`

netErrAuthFailure  
netErrPPPAddressRefused

**Sockets  
Equivalent**      None

**Comments**      The net library must be open before this call can be made. For dial-up interfaces, this call will dial up the modem if necessary and run through the connect script to establish the connection.  
  
If the interface is already up, this routine returns immediately with no error. This call doesn't take a timeout parameter because it relies on each interface to have its own established timeout setting.

**See Also**      [NetLibIFGet](#), [NetLibIFAttach](#), [NetLibIFDetach](#),  
[NetLibIFDown](#)

## NetLibMaster

**Purpose**      Retrieves the network statistics, interface statistics, and the contents of the trace buffer.

**Declared In**      NetMgr.h

**Prototype**      Err NetLibMaster (UInt16 libRefNum, UInt16 cmd,  
NetMasterPBPtr pbP, Int32 timeout)

**Parameters**

|              |                                                                                                                                                                                                                                                                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> libRefNum | Reference number of the net library.                                                                                                                                                                                                                                                                                                                                      |

| <-> pbP      | Command parameter block.                                                                                                                                                                                                                                                                                                                                                  |

## Net Library

### Net Library Functions

---

-> timeout            Timeout in ticks; -1 means wait forever.

**Result**    Returns one of the following values:

0                    No error

netErrNotOpen    The referenced net library has not been opened yet.

netErrParamErr

netErrUnimplemented

**Sockets Equivalent**

None

**Comments**    This call allows applications to get detailed information about the net library. This information is usually helpful in debugging network configuration problems.

This function takes a command word (cmd) and parameter block pointer (pbP) as arguments and returns its results in the parameter block on exit. Which values you must specify in the parameter block and which values are returned are specific to the command you specify.

#### **netMasterInterfaceInfo**

The pbP->interfaceInfo struct specifies interface information.

-> index            Index of interface to fetch info about.

<- creator        Creator of interface.

<- instance       Instance of interface.

<- netIFP         Private interface info pointer.

<- drvvrName      Driver type that interface uses ("PPP", "SLIP", etc.).

<- hwName         Hardware driver name ("Serial Library", etc.).

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <- localNetHdrLen     | Number of bytes in local net header.              |
| <- localNetTrailerLen | Number of bytes in local net trailer.             |
| <- localNetMaxFrame   | Local net maximum frame size.                     |
| <- ifName             | Interface name with instance number concatenated. |
| <- driverUp           | true if interface driver is up.                   |
| <- ifUp               | true if interface media layer is up.              |
| <- hwAddrLen          | Length of interface's hardware address.           |
| <- hwAddr             | Interface's hardware address.                     |
| <- mtu                | Maximum transfer unit of interface.               |
| <- speed              | Speed in bits per second.                         |
| <- lastStateChange    | Time in milliseconds of last state change.        |
| <- ipAddr             | IP address of interface.                          |
| <- subnetMask         | Subnet mask of local network.                     |
| <- broadcast          | Broadcast address of local network.               |

### **netMasterInterfaceStats**

The `pbP->interfaceStats` structure specifies interface statistics.

|                 |                                                 |
|-----------------|-------------------------------------------------|
| -> index        | Index of interface to fetch info about.         |
| <- inOctets     | Number of octets received.                      |
| <- inUcastPkts  | Number of packets received.                     |
| <- inNUcastPkts | Number of broadcast packets received.           |
| <- inDiscards   | Number of incoming packets that were discarded. |

## Net Library

### Net Library Functions

---

|                    |                                          |
|--------------------|------------------------------------------|
| <- inErrors        | Number of packet errors encountered.     |
| <- inUnknownProtos | Number of unknown protocols encountered. |
| <- outOctets       | Number octets sent.                      |
| <- outUcastPkts    | Number of packets sent.                  |
| <- outNUcastPkts   | Number of broadcast packets sent.        |
| <- outDiscards     | Number of packets discarded.             |
| <- outErrors       | Number of outbound packet errors.        |

#### **netMasterIPStats**

The `pbP->ipStats` structure contains statistics about the IP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterICMPStats**

The `pbP->icmpStats` structure contains statistics about the ICMP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterUDPStats**

The `pbP->udpStats` structure contains statistics about the UDP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterTCPStats**

The `pbP->tcpStats` structure contains statistics about the TCP protocol. See `NetMgr.h` for a complete list of statistics returned.

#### **netMasterTraceEventGet**

The `pbP->traceEventGet` structure contains a trace event.

|          |                                                                               |
|----------|-------------------------------------------------------------------------------|
| -> index | Index of event to fetch.                                                      |
| <- textP | Pointer to text string to return event in. Should be at least 256 bytes long. |

| <b>Prototype</b>   | Err NetLibOpen (UInt16 libRefnum,<br>UInt16 *netIFErrsP)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | -> libRefnum      Reference number of the net library.<br><- netIFErrsP    First error encountered when bringing up<br>network interfaces. (See <a href="#">NetLibIFUp</a> for a list<br>of possible values.)                                                                                                                                                                                                                                                                                                                                    |
| <b>Result</b>      | Returns one of the following values:<br>0                    No error.<br>netErrAlreadyOpen      Not really an error; returned if library was<br>already open and the open count was simply<br>incremented.<br>netErrOutOfMemory      Not enough memory available to open the<br>library.<br>netErrNoInterfaces      Incorrect setup.<br>netErrPrefNotFound      Incorrect setup.                                                                                                                                                                |
| <b>Comments</b>    | Applications must call this function before using the net library. If the net library was already open, NetLibOpen increments its open count. Otherwise, it opens the library, initializes it, starts up the net protocol stack component of the library as a separate task, and brings up all attached network interfaces.<br><br>NetLibOpen uses settings saved in the net library's preferences database during initialization. These settings include the interfaces to attach, the IP addresses, etc. It's assumed that these settings have |

## Net Library

### Net Library Functions

---

been previously set up by a preference panel or equivalent so an application doesn't normally have to set them up before calling `NetLibOpen`.

If any of the attached interfaces fails to come up, `*netIFErrsP` will contain the error number of the first interface that encountered a problem.

**Compatibility** `NetLibOpen` behaves slightly differently in version 3.2 and later than it does in previous releases. In version 3.2 and later, `NetLibOpen` calls [NetLibOpenConfig](#) specifying the default configuration. `NetLibOpenConfig` reverts all settings to their saved, default values before opening the net library.

**See Also** [SysLibFind](#), [NetLibClose](#), [NetLibOpenCount](#)

---

## **New** `NetLibOpenConfig`

**Purpose** Opens and initializes the net library with the specified configuration.

**Prototype** `Err NetLibOpenConfig (UInt16 refNum,  
UInt16 configIndex, UInt32 openFlags,  
UInt16 *netIFErrP)`

**Parameters**

- > `refNum` Reference number of the net library.
- > `configIndex` Index of the configuration to use. 0 means use the default configuration as defined in the Network preferences panel.
- > `openFlags` Not used. Pass 0 for this parameter.
- <- `netIFErrP` Pointer to return error code for interfaces.

**Result** Returns one of the following values:

0 No error.  
`memErrNotEnoughSpace`

`netErrAlreadyOpen`  
Not really an error; returned if library was already open and the open count was simply incremented.

`netErrAlreadyOpenWithAnotherConfig`  
Another application has the net library open with a configuration that is incompatible with the one specified.

`netErrBufTooSmall`

`netErrConfigAliasErr`  
A configuration alias was specified, but the alias could not be resolved.

`netErrConfigCantDelete`

`netErrConfigEmpty`  
The configuration is not defined.

`netErrConfigNotFound`  
The specified configuration index is invalid.

`netErrInterfaceNotFound`

`netErrOutOfCmdBlocks`

`netErrOutOfMemory`  
Not enough memory available to open the library.

`netErrNoInterfaces`  
Incorrect setup.

`netErrParamErr`

`netErrPrefNotFound`  
Incorrect setup.

`netErrTimeout`

**Sockets Equivalent**

None

**Comments**

Use this routine instead of [NetLibOpen](#) when you want to open the net library with a non-default configuration. If the default net library configuration is not suitable for your application, you may

## Net Library

### Net Library Functions

---

use one of the built-in aliases to specify a configuration that is suitable (see “[Configuration Aliases](#)”).

`NetLibOpenConfig` tries to open the net library and initialize it with the specified configuration. If another application has the net library open with an incompatible configuration, it returns an error. If the net library is in the close-wait state, this function completely closes the net library and then reopens it using the new configuration. If the net library can be opened with the new configuration, `NetLibOpenConfig` first saves the current configuration so that it can be restored when your application closes the net library.

Typically, applications use the [NetLibConfigList](#) function to obtain the list of available configurations and present this list to the user. Then they call [NetLibConfigIndexFromName](#) with the user’s selection to get the index of the configuration that the user selected.

The constant `netConfigIndexCurSettings` specifies the current configuration. You can specify `netConfigIndexCurSettings` as the `configIndex` for testing purposes.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

**See Also** [NetLibOpen](#), [SysLibFind](#), [NetLibClose](#), [NetLibOpenCount](#)

## NetLibOpenCount

**Purpose** Retrieves the open count of the net library.

**Declared In** `NetMgr.h`

**Prototype** `Err NetLibOpenCount (UInt16 refNum,  
UInt16 *countP)`

**Parameters** `-> refNum` Reference number of the net library.

<- countP            Contains the open count of the net library upon return.

**Result**            Always returns 0.

**Sockets Equivalent**    None.

**Comments**            This call will most likely only be used by the Network preferences panel. Most applications will simply call [NetLibOpen](#) unconditionally during startup and [NetLibClose](#) when they exit.

## NetLibReceive

**Purpose**            Receive data from a socket into a single buffer.

**Declared In**        NetMgr.h

**Prototype**        Int16 NetLibReceive (UInt16 libRefNum,  
NetSocketRef socket, void \*bufP, UInt16 bufLen,  
UInt16 flags, void \*fromAddrP, UInt16 \*fromLenP,  
Int32 timeout, Err \*errP)

**Parameters**

|              |                                                                                            |
|--------------|--------------------------------------------------------------------------------------------|
| -> libRefNum | Reference number of the net library.                                                       |
| -> socket    | Descriptor for the open socket.                                                            |
| <- bufP      | Pointer to buffer to hold received data.                                                   |
| -> bufLen    | Length of bufP buffer.                                                                     |
| -> flags     | One or more netIOFlagxxx flags. See " <a href="#">I/O Flags</a> ."                         |
| <- fromAddrP | Pointer to buffer to hold address of sender (a <a href="#">NetSocketAddrType</a> ).        |
| <-> fromLenP | On entry, size of fromAddrP buffer. On exit, actual size of returned address in fromAddrP. |
| -> timeout   | Maximum timeout in system ticks; -1 means wait forever.                                    |

## Net Library

### Net Library Functions

---

<- errP                      Contains an error code if the return value is -1.

**Result**      Returns the number of bytes successfully received. If the return value is 0, the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and errP contains one of the following values:

0                              No error.

netErrTimeout      Call timed out.

netErrNotOpen      The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrWouldBlock

netErrUserCancel

**Sockets  
Equivalent**

```
int recvfrom (int socket, const void *bufP,  
int bufLen, int flags, const void *fromAddrP,  
int *fromLenP);
```

```
int recv (int socket, const void *bufP,  
int bufLen, int flags);
```

```
int read (int socket, const void *bufP,  
int bufLen);
```

**Comments**      For stream-based sockets, this call reads whatever bytes are available and returns the number of bytes actually read into the caller's buffer. If there is no data available, this call will block until at least one byte arrives, until the socket is shut down by the remote host, or until a timeout occurs.

For datagram-based sockets, this call reads a complete datagram and returns the number of bytes in the datagram. If the caller's buffer is not large enough to hold the entire datagram, the end of the datagram is discarded. If a datagram is not available, this call will block until one arrives, or until the call times out.

The data is read into a single buffer pointed to by `bufP`.

**See Also** [NetLibReceive](#), [NetLibDmReceive](#), [NetUReadN](#), [NetLibSend](#), [NetLibSendPB](#)

## NetLibReceivePB

**Purpose** Receive data from a socket into a multi-buffer gather-read array.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibReceivePB (UInt16 libRefNum,  
NetSocketRef socket, NetIOParamType *pbP,  
UInt16 flags, Int32 timeout, Err *errP)`

**Parameters**

|                           |                                                                                 |
|---------------------------|---------------------------------------------------------------------------------|
| -> <code>libRefNum</code> | Reference number of the net library.                                            |
| -> <code>socket</code>    | Descriptor for the open socket.                                                 |
| -> <code>pbP</code>       | Pointer to parameter block containing buffer info.                              |
| -> <code>flags</code>     | One or more <code>netIOFlagxxx</code> flags. See " <a href="#">I/O Flags</a> ." |
| -> <code>timeout</code>   | Maximum timeout in system ticks; -1 means wait forever.                         |
| <- <code>errP</code>      | Contains an error code if the return value is -1.                               |

**Result** Returns the number of bytes successfully received. Returns 0 if the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and `errP` contains one of the following values:

|                                  |                                                     |
|----------------------------------|-----------------------------------------------------|
| 0                                | No error.                                           |
| <code>netErrTimeout</code>       | Call timed out.                                     |
| <code>netErrNotOpen</code>       | The referenced net library has not been opened yet. |
| <code>netErrParamErr</code>      |                                                     |
| <code>netErrSocketNotOpen</code> |                                                     |

## Net Library

### Net Library Functions

---

netErrWouldBlock

#### Sockets Equivalent

```
int recvmsg (int socket, const struct msghdr *pbP,  
int flags);
```

#### Comments

The pbP parameter is a pointer to a NetIOParamType structure. NetIOParamType is defined as follows:

```
typedef struct {  
    UInt8      *addrP;  
    UInt16     addrLen;  
    NetIOVecPtr iov;  
    UInt16     iovLen;  
    UInt8      *accessRights;  
    UInt16     accessRightsLen;  
} NetIOParamType, *NetIOParamPtr;
```

You provide the following information in this struct:

|                 |                                                                                                                                                                                                                                                                           |      |                      |        |                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|----------------------|--------|-----------------|
| addrP           | Address of sender, set by NetLibReceivePB. Set to 0 if you don't require this field.                                                                                                                                                                                      |      |                      |        |                 |
| addrLen         | Length of *addrP.                                                                                                                                                                                                                                                         |      |                      |        |                 |
| iov             | Array of buffers into which the data should be received. NetIOVecPtr is a pointer to a NetIOVecType structure, which has two fields:<br><table><tbody><tr><td>bufP</td><td>Pointer to a buffer.</td></tr><tr><td>bufLen</td><td>Length of bufP.</td></tr></tbody></table> | bufP | Pointer to a buffer. | bufLen | Length of bufP. |
| bufP            | Pointer to a buffer.                                                                                                                                                                                                                                                      |      |                      |        |                 |
| bufLen          | Length of bufP.                                                                                                                                                                                                                                                           |      |                      |        |                 |
| iovLen          | Length of the iov array.                                                                                                                                                                                                                                                  |      |                      |        |                 |
| accessRights    | Access rights. This field currently isn't used and should be set to 0.                                                                                                                                                                                                    |      |                      |        |                 |
| accessRightsLen | Length of the *accessRights. This field currently isn't used and should be set to 0.                                                                                                                                                                                      |      |                      |        |                 |

For stream-based sockets, this call reads whatever bytes are available and returns the number of bytes actually read into the caller's buffer. If no data is available, this call will block until at least

one byte arrives, until the socket is shut down by the remote host, or until a timeout occurs.

For datagram-based sockets, this call reads a complete datagram and returns the number of bytes in the datagram. If the caller's buffer is not large enough to hold the entire datagram, the end of the datagram is discarded. If a datagram is not available, this call will block until one arrives, or until the call times out.

The data is read into the gather-read array specified by the `pbP->iov` array.

## NetLibSelect

**Purpose** Blocks until I/O is ready on one or more descriptors, where a descriptor can represent socket input, socket output, or a user input event like a pen tap or key press.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibSelect (UInt16 libRefNum, UInt16 width, NetFDSetType *readFDs, NetFDSetType *writeFDs, NetFDSetType *exceptFDs, Int32 timeout, Err *errP)`

**Parameters**

|                                 |                                                                                                                                      |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; libRefNum</code>    | Reference number of the net library.                                                                                                 |
| <code>-&gt; width</code>        | Number of descriptor bits to check in the <code>readFDs</code> , <code>writeFDs</code> , and <code>exceptFDs</code> descriptor sets. |
| <code>&lt;-&gt; readFDs</code>  | Pointer to 32-bit <code>NetFDSetType</code> containing set of bits representing descriptors to check for input.                      |
| <code>&lt;-&gt; writeFDs</code> | Pointer to 32-bit <code>NetFDSetType</code> containing set of bits representing descriptors to check for output.                     |

## Net Library

### Net Library Functions

---

|                                  |                                                                                                                                                                                                     |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; exceptFDs</code> | Pointer to 32-bit <code>NetFDSetType</code> containing set of bits representing descriptors to check for exception conditions. This parameter is ignored. Upon return, its bits are always cleared. |
| <code>-&gt; timeout</code>       | Maximum timeout in system ticks; -1 means wait forever.                                                                                                                                             |
| <code>&lt;- errP</code>          | Contains an error code if the return value is -1.                                                                                                                                                   |

**Result** Returns the sum total number of ready file descriptors in `*readFDs`, `*writeFDs`, and `*exceptFDs`. Returns 0 upon timeout. If the return value is -1, an error has occurred, and `errP` contains one of the following values:

|                            |                                                     |
|----------------------------|-----------------------------------------------------|
| 0                          | No error                                            |
| <code>netErrTimeout</code> | Call timed out.                                     |
| <code>netErrNotOpen</code> | The referenced net library has not been opened yet. |

#### Sockets Equivalent

```
int select (int width, fd_set *readfds,
fd_set *writefds, fd_set *exceptfds,
struct timeval *timeout);
```

#### Comments

This call blocks until one or more descriptors are ready for I/O. In the Palm OS environment, a descriptor is either a `NetSocketRef` or the "stdin" descriptor, `sysFileDescStdIn`. The `sysFileDescStdIn` descriptor will be ready for input whenever a user event is available like a pen tap or key press.

The caller should set which bits in each descriptor set need to be checked by using the `netFDZero` and `netFDSet` macros. After this call returns, the macro `netFDIsSet` can be used to determine which descriptors in each set are actually ready.

On exit, the total number of ready descriptors is returned and each descriptor set is updated with the appropriate bits set for each ready descriptor in that set.

The following example illustrates how to use this call to check for input on a socket or a user event:

```
Err      err;
NetSocketRef  socket;
NetFDSetType  readFDs,writeFDs,exceptFDs;
Int16      numFDs;
UInt16      width;

// Create the descriptor sets
netFDZero(&readFDs);
netFDZero(&writeFDs);
netFDZero(&exceptFDs);
netFDSet(sysFileDescStdIn, &readFDs);
netFDSet(socket, &readFDs);

// Calculate the max descriptor number and
// use that +1 as the max width.
// Alternatively, we could simply use the
// constant netFDSetSize as the width which
// is simpler but makes the NetLibSelect call
// slightly slower.
width = sysFileDescStdIn;
if (socket > width) width = socket;

// Wait for any one of the descriptors to be
// ready.
numFDs = NetLibSelect(AppNetRefnum, width+1,
    &readFDs, &writeFDs, &exceptFDs,
    AppNetTimeout, &err);
```

Also see the NetSample example application in the Palm OS Examples folder. The function CmdTelnet in the file CmdTelnet.c shows how to use the Berkeley sockets select function and how to interpret the results.

| <b>Result</b>       | Returns the number of bytes successfully sent. Returns 0 if the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and errP contains one of the following values: <table><tr><td>0</td><td>No error.</td></tr><tr><td>netErrTimeout</td><td>Call timed out.</td></tr><tr><td>netErrNotOpen</td><td>The referenced net library has not been opened yet.</td></tr><tr><td>netErrParamErr</td><td></td></tr><tr><td>netErrSocketNotOpen</td><td></td></tr></table>                                                                                                                                                                                                                                                                | 0            | No error.                            | netErrTimeout | Call timed out.                 | netErrNotOpen | The referenced net library has not been opened yet. | netErrParamErr |                         | netErrSocketNotOpen |                                                                    |            |                                                                               |          |                         |            |                                                         |         |                                                   |

**Sockets  
Equivalent**

```
int sendto (int socket, const void *bufP,
int buflen, int flags, const void *toAddrP,
int toLen);

int send (int socket, const void *bufP,
int buflen, int flags);

int write (int socket, const void *bufP,
int buflen,);
```

**Comments**

This call attempts to write data to the specified socket and returns the number of bytes actually sent, which may be less than or equal to the requested number of bytes. The data is passed in a single buffer that bufP points to.

For datagram sockets, you must only send a single packet at a time. If the data is too large to fit in a single UDP packet (1536 bytes), no data is sent and -1 is returned.

The `toAddrP` field applies only to datagram sockets without an existing connection. An error is returned if the datagram socket was previously connected and `toAddrP` is specified. Stream-based sockets, by definition, must have a connection established with a remote host before data can be written. Raw sockets (supported in Palm OS version 3.0 and higher) must construct the entire IP header, including the destination address, before data can be sent; thus, the address is taken from the data to be sent.

If there isn't enough buffer space to send any data, this call will block until there is enough buffer space, or until a timeout.

---

**NOTE:** For stream-based sockets, this call may write only a portion of the desired data. It always returns the number of bytes actually written. Consequently, the caller should be prepared to call this routine repeatedly until the desired number of bytes have been written, or until it returns 0 or -1.

## NetLibSendPB

**Purpose** Send data to a socket from a scatter-write array.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibSendPB (UInt16 libRefNum,  
NetSocketRef socket, NetIOParamType *pbP,  
UInt16 flags, Int32 timeout, Err *errP)`

**Parameters**

|              |                                                                                                             |
|--------------|-------------------------------------------------------------------------------------------------------------|
| -> libRefNum | Reference number of the net library.                                                                        |
| -> socket    | Descriptor for the open socket.                                                                             |
| -> pbP       | Pointer to parameter block containing buffer info. See the description in <a href="#">NetLibReceivePB</a> . |

-> flags            One or more netIOFlagxxx flags. See "[I/O Flags](#)."

-> timeout          Maximum timeout in system ticks; -1 means wait forever.

<- errP            Contains an error code if the return value is -1.

**Result**          Returns the number of bytes successfully sent. Returns 0 if the socket has been shut down by the remote host. If the return value is -1, an error has occurred, and errP contains one of the following values:

0                    No error.

netErrTimeout      Call timed out.

netErrNotOpen      The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrMessageTooBig

netErrSocketNotConnected

netErrSocketClosedByRemote

netErrIPCantFragment

netErrIPNoRoute

netErrIPNoSrc

netErrIPNoDst

netErrIPktOverflow

netErrOutOfCmdBlocks

netErrOutOfPackets

netErrInterfaceNotFound

netErrInterfaceDown

netErrUnreachableDest

netErrNoMultiPktAddr

netErrWouldBlock

## Net Library

### Net Library Functions

---

**Sockets Equivalent** `int sendmsg (int socket, const struct msghdr *pbP, int flags);`

**Comments** This call attempts to write data to the given socket and returns the number of bytes actually sent, which may be less than or equal to the requested number of bytes. The data is passed in the scatter-write array specified in the `pbP` parameter block.

For datagram sockets, you must only send a single packet at a time. If the data is too large to fit in a single UDP packet, no data is sent and -1 is returned.

The `toAddrP` field applies only to datagram sockets without an existing connection. An error is returned if the datagram socket was previously connected and `toAddrP` is specified. Stream-based sockets, by definition, must have a connection established with a remote host before data can be written. Raw sockets (supported in Palm OS version 3.0 and higher) must construct the entire IP header, including the destination address, before data can be sent; thus, the address is taken from the data to be sent.

If there isn't enough buffer space to send any data, this call will block until there is space, or until a timeout.

---

**NOTE:** For stream-based sockets, this call may write only a portion of the desired data. It always returns the number of bytes actually written. Consequently, the caller should be prepared to call this routine repeatedly until the desired number of bytes have been written, or until it returns 0 or -1.

| <b>Comments</b>           | This call retrieves the current value of any general setting. The caller must pass a pointer to a buffer to hold the return value (valueP), the size of the buffer (*valueLenP), and the setting ID (setting). The setting ID is one of the NetSettingEnum constants in the netSettingEnum type.                                                                                                                                   |              |                                      |                      |                                                           |                    |                                    |                   |                                                                                               |                    |  |

## Net Library

### *Net Library Functions*

---

Some settings, such as the host table, are variable size. For these types of settings, you can obtain the actual size required for the buffer by passing 0 for \*valueLenP. The required size is returned in valueLenP.

[Table 61.3](#) lists the general settings and the type of each setting.

**Table 61.3 Net Library General Settings**

| netSetting...     | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ResetAll          | void    | Used for <a href="#">NetLibSettingSet</a> only. This will clear all other settings to their default values.                                                                                                                                                                                                                                                                                                           |
| PrimaryDNS        | UInt32  | IP address of primary DNS server. This setting must be set to a non-zero IP address in order to support any of the name lookup calls.                                                                                                                                                                                                                                                                                 |
| SecondaryDNS      | UInt32  | IP address of secondary DNS server. Set to 0 to have stack ignore this setting.                                                                                                                                                                                                                                                                                                                                       |
| DefaultRouter     | UInt32  | IP address of default router. Default value is 0 which is appropriate for most implementations with only one attached interface (besides loopback). Packets with destination IP addresses that don't lie in the subnet of an attached interface will be sent to this router through the default interface specified by the <code>netSettingDefaultIFCreator/</code><br><code>netSettingDefaultIFInstance</code> pair. |
| DefaultIFCreator  | UInt32  | Creator of the default network interface. Default value is 0, which is appropriate for most implementations. Packets with destination IP addresses that don't lie in the subnet of a directly attached interface are sent through this interface. If this setting is 0, the stack automatically makes the first non-loopback interface the default interface.                                                         |
| DefaultIFInstance | UInt16  | Instance number of the default network interface. Packets with destination IP addresses that don't lie in the subnet of an attached interface are sent through the default interface. Default value is 0.                                                                                                                                                                                                             |
| HostName          | Char [] | A zero-terminated character string of 64 bytes or less containing the host name of this machine. This setting is not actually used by the stack. It's present mainly for informative purposes and to support the <code>gethostname/sethostname</code> sockets API calls. To clear the host name, call <a href="#">NetLibIFSettingSet</a> with a <code>valueLen</code> of 0.                                           |

**Table 61.3 Net Library General Settings (continued)**

| netSetting... | Type    | Description                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DomainName    | Char [] | A zero-terminated character string of 256 bytes or less containing the default domain. This default domain name is appended to all host names before name lookups are performed. If the name is not found, the host name is looked up again without appending the domain name to it. To have the stack not use the domain name, call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0.  |
| HostTbl       | Char [] | A null-terminated character string containing the host table. This table is consulted first before sending a DNS query to the DNS server(s). To have the stack not use a host table, call <a href="#">NetLibIFSettingSet</a> with a valueLen of 0. The format of a host table is a series of lines separated by '\n' in the following format:<br><pre>host.company.com A 111.222.333.444</pre> |
| CloseWaitTime | UInt32  | The close-wait time in milliseconds. This setting must be specified. See the discussion of the <a href="#">NetLibClose</a> call for an explanation of the close-wait time.                                                                                                                                                                                                                     |
| TraceBits     | UInt32  | A bitfield of various trace bits. See “ <a href="#">Tracing Bits.</a> ” Default value is (netTracingErrors   netTracingAppMsgs). An application can get a list of events in the trace buffer using the <a href="#">NetLibMaster</a> call.                                                                                                                                                      |
| TraceSize     | UInt32  | Maximum trace buffer size in bytes. Setting this setting always clears the existing trace buffer. Default is 2 KB.                                                                                                                                                                                                                                                                             |
| TraceRoll     | UInt8   | Boolean value, default is true (non-zero). If true, trace buffer will roll over when it fills. If false, tracing will stop as soon as trace buffer fills.                                                                                                                                                                                                                                      |

| <b>Comments</b>           | <p>This call can be used to set the current value of any general setting. The caller must pass a pointer to a buffer which holds the new value (valueP), the size of the buffer (valueLen), and the setting ID (setting). The setting ID is one of the netSettingXXX constants in the NetSettingEnum type.</p> <p>If the net library is not open at the time this call is made, the setting is stored in the active configuration. You need to save the active configuration using <a href="#">NetLibConfigSaveAs</a> if you want the new</p> |              |                                      |                      |                                                                                       |                          |                                             |                    |                      |                       |  |

## Net Library

### Net Library Functions

---

value of the setting to be used the next time the net library is opened.

See [NetLibSettingGet](#) for an explanation of each of the settings.

Of particular interest is the `netSettingResetAll` setting, which, if used, will reset all general settings to their default values. When using this setting, `valueP` and `valueLen` are ignored.

**See Also** [NetLibSettingGet](#), [NetLibSettingSet](#),  
[NetLibIFSettingSet](#), [NetLibMaster](#)

## NetLibSocketAccept

**Purpose** Accept a connection from a stream-based socket.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibSocketAccept (UInt16 libRefnum,  
NetSocketRef socket,  
NetSocketAddrType *sockAddrP, Int16 *addrLenP,  
Int32 timeout, Err *errP)`

**Parameters**

|              |                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| -> libRefNum | Reference number of the net library.                                                                                                      |
| -> socket    | Descriptor for the open socket.                                                                                                           |
| <- sockAddrP | Address of remote host is returned here.                                                                                                  |
| <->addrLenP  | On entry, length of <code>sockAddrP</code> buffer in bytes.<br>On exit, length of returned address stored in<br><code>*sockAddrP</code> . |
| -> timeout   | Maximum timeout in system ticks; -1 means<br>wait forever.                                                                                |
| <- errP      | Contains an error code if the return value is -1.                                                                                         |

**Result** Returns the `NetSocketRef` of the new socket. If the return value is -1, an error has occurred, and `errP` contains one of the following values:

|   |           |
|---|-----------|
| 0 | No error. |
|---|-----------|

netErrTimeout    Call timed out.  
netErrNotOpen    The referenced net library has not been opened yet.  
netErrParamErr  
netErrSocketNotOpen  
netErrSocketNotConnected  
netErrSocketClosedByRemote  
netErrWrongSocketType  
netErrSocketNotListening  
netErrUnimplemented

**Sockets Equivalent**

```
int accept (int socket, void *sockAddrP,  
int *addrLenP);
```

**Comments**

Accepts the next connection request from a remote client. This call is only applicable to stream-based sockets. Before calling `NetLibSocketAccept` on a socket, a server application needs to:

- Open the socket ([NetLibSocketOpen](#)).
- Bind the socket to a local address ([NetLibSocketBind](#)).
- Set the maximum pending connection-request queue length ([NetLibSocketListen](#)).

`NetLibSocketAccept` will block until a successful connection request is obtained from a remote client. After a successful connection is made, this call returns with the address of the remote host in `*sockAddrP` and the socket descriptor of a **new** socket as the return value. You then use the new socket to send and receive data.

**See Also**

[NetLibSocketBind](#), [NetLibSocketListen](#)

## **NetLibSocketAddr**

- Purpose** Returns the local and remote addresses currently associated with a socket.
- Declared In** `NetMgr.h`
- Prototype**
- ```
Int16 NetLibSocketAddr (UInt16 libRefnum,  
NetSocketRef socketRef,  
NetSocketAddrType *locAddrP, Int16 *locAddrLenP,  
NetSocketAddrType *remAddrP, Int16 *remAddrLenP,  
Int32 timeout, Err *errP)
```
- Parameters**
- > `libRefNum` Reference number of the net library.
  - > `socketRef` Descriptor for the open socket.
  - <- `locAddrP` Local address of socket is returned here.
  - <-> `locAddrLenP` On entry, length of `locAddrP` buffer in bytes.  
On exit, length of returned address stored in `*locAddrP`.
  - <- `remAddrP` Address of remote host is returned here.
  - <-> `remAddrLenP` On entry, length of `remAddrP` buffer in bytes.  
On exit, length of returned address stored in `*remAddrP`.
  - > `timeout` Maximum timeout in system ticks; -1 means wait forever.
  - <- `errP` Contains an error code if the return value is -1.
- Result** Returns 0 upon success and -1 if an error occurred. If the return value is -1, `errP` contains one of the following values:
- 0 No error.
  - `netErrTimeout` Call timed out.
  - `netErrNotOpen` The referenced net library has not been opened yet.
  - `netErrParamErr`

```
netErrSocketNotOpen  
netErrSocketClosedByRemote  
netErrOutOfCmdBlocks
```

**Sockets Equivalent**

```
int getpeername (int s, struct sockaddr *name,  
int *namelen);  
  
int getsockname (int s, struct sockaddr *name,  
int *namelen);
```

**Comments** This call is mainly useful for stream-based sockets. It allows the caller to find out what address was bound to a connected socket and the address of the remote host that it's connected to.

In Palm OS version 3.0 and higher, if you pass a raw socket to this function, it returns the instance number and creator of the interface to which the socket is bound.

**See Also** [NetLibSocketBind](#), [NetLibSocketConnect](#), [NetLibSocketAccept](#)

## NetLibSocketBind

**Purpose** Assign a local address to a socket.

**Declared In** NetMgr.h

**Prototype**

```
Int16 NetLibSocketBind (UInt16 libRefnum,  
NetSocketRef socket,  
NetSocketAddrType *sockAddrP, Int16 addrLen,  
Int32 timeout, Err *errP)
```

**Parameters**

-> libRefNum	Reference number of the net library.
-> socket	Descriptor for the open socket.
-> sockAddrP	Pointer to the address to give to the socket. This can be a <a href="#">NetSocketAddrIntType</a> or a <a href="#">NetSocketAddrRawType</a> .
-> addrLen	Length of address in *sockAddrP.

## Net Library

### Net Library Functions

---

-> timeout           Maximum timeout in system ticks; -1 means wait forever.

<- errP               Contains an error code if the return value is -1.

**Result**           Returns 0 upon success and -1 if an error occurred. If an error occurred, errP contains one of the following values:

0                     No error.

netErrTimeout        Call timed out.

netErrNotOpen        The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrSocketAlreadyConnected

netErrSocketClosedByRemote

netErrOutOfCmdBlocks

**Sockets Equivalent**   int bind (int socket, const void \*sockAddrP, int addrLen);

**Comments**           Applications that want to wait for an incoming connection request from a remote host must call this function. After calling `NetLibSocketBind`, applications can call [NetLibSocketListen](#) and then [NetLibSocketAccept](#) to make the socket ready to accept connection requests.

**Compatibility**       Raw sockets are only supported in Palm OS version 3.0 and higher. See [NetLibSocketOpen](#) for instructions on how to bind raw sockets.

**See Also**           [NetLibSocketConnect](#), [NetLibSocketListen](#), [NetLibSocketAccept](#)

## NetLibSocketClose

<b>Purpose</b>	Close a socket.												
<b>Declared In</b>	NetMgr.h												
<b>Prototype</b>	<pre>Int16 NetLibSocketClose (UInt16 libRefnum, NetSocketRef socket, Int32 timeout, Err *errP)</pre>												
<b>Parameters</b>	<table><tr><td>-&gt; libRefNum</td><td>Reference number of the net library.</td></tr><tr><td>-&gt; socket</td><td>Descriptor for the open socket.</td></tr><tr><td>-&gt; timeout</td><td>Maximum timeout in system ticks; -1 means wait forever.</td></tr><tr><td>&lt;- errP</td><td>Contains an error code if the return value is -1.</td></tr></table>	-> libRefNum	Reference number of the net library.	-> socket	Descriptor for the open socket.	-> timeout	Maximum timeout in system ticks; -1 means wait forever.	<- errP	Contains an error code if the return value is -1.				
-> libRefNum	Reference number of the net library.												
-> socket	Descriptor for the open socket.												
-> timeout	Maximum timeout in system ticks; -1 means wait forever.												
<- errP	Contains an error code if the return value is -1.												
<b>Result</b>	Returns 0 upon success and -1 if an error occurred. If an error occurred, errP contains one of the following values: <table><tr><td>0</td><td>No error.</td></tr><tr><td>netErrTimeout</td><td>Call timed out.</td></tr><tr><td>netErrNotOpen</td><td>The referenced net library has not been opened yet.</td></tr><tr><td>netErrParamErr</td><td></td></tr><tr><td>netErrSocketNotOpen</td><td></td></tr><tr><td>netErrOutOfCmdBlocks</td><td></td></tr></table>	0	No error.	netErrTimeout	Call timed out.	netErrNotOpen	The referenced net library has not been opened yet.	netErrParamErr		netErrSocketNotOpen		netErrOutOfCmdBlocks	
0	No error.												
netErrTimeout	Call timed out.												
netErrNotOpen	The referenced net library has not been opened yet.												
netErrParamErr													
netErrSocketNotOpen													
netErrOutOfCmdBlocks													
<b>Sockets Equivalent</b>	<pre>int close (int socket);</pre>												
<b>Comments</b>	Closes down a socket and frees all memory associated with it.												
<b>See Also</b>	<a href="#">NetLibSocketOpen</a> , <a href="#">NetLibSocketShutdown</a>												

## **NetLibSocketConnect**

**Purpose** Assign a destination address to a socket and initiate three-way handshake if it's stream based.

**Declared In** NetMgr.h

**Prototype** `Int16 NetLibSocketConnect (UInt16 libRefnum,  
NetSocketRef socket,  
NetSocketAddrType *sockAddrP, Int16 addrLen,  
Int32 timeout, Err *errP)`

**Parameters**

-> libRefNum	Reference number of the net library.
-> socket	Descriptor for the open socket.
-> sockAddrP	Pointer to address to connect to.
-> addrLen	Length of address in *sockAddrP.
-> timeout	Maximum timeout in system ticks; -1 means wait forever.
<- errP	Contains an error code if the return value is -1.

**Result** Returns 0 upon success and -1 if an error occurred. If an error occurred, errP contains one of the following values:

0	No error.
netErrTimeout	Call timed out.
netErrNotOpen	The referenced net library has not been opened yet.
netErrParamErr	
netErrSocketNotOpen	
netErrSocketBusy	
netErrNoInterfaces	Incorrect setup.
netErrPortInUse	
netErrQuietTimeNotElapsed	

```
netErrInternal  
netErrSocketAlreadyConnected  
netErrSocketClosedByRemote  
netErrTooManyTCPConnections  
netErrWouldBlock  
netErrWrongSocketType  
netErrOutOfCmdBlocks
```

**Sockets Equivalent** `int connect (int socket, const void *sockAddrP, int addrLen);`

**See Also** [NetLibSocketBind](#), [NetUTCPOpen](#)

## NetLibSocketListen

**Purpose** Put a stream-based socket into passive listen mode.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibSocketListen (UInt16 libRefnum, NetSocketRef socket, UInt16 queueLen, Int32 timeout, Err *errP)`

**Parameters**

<code>-&gt; libRefNum</code>	Reference number of the net library.
<code>-&gt; socket</code>	Descriptor for the open socket.
<code>-&gt; queueLen</code>	Maximum number of pending connections allowed.
<code>-&gt; timeout</code>	Maximum timeout in system ticks; -1 means wait forever.
<code>&lt;- errP</code>	Contains an error code if the return value is -1.

**Result** Returns 0 upon success and -1 if an error occurred. If an error occurred, `errP` contains one of the following values:

0	No error.
---	-----------

## Net Library

### Net Library Functions

---

`netErrTimeout` Call timed out.

`netErrNotOpen` The referenced net library has not been opened yet.

`netErrParamErr`

`netErrOutOfResources`

`netErrSocketNotOpen`

`netErrSocketBusy`

`netErrNoInterfaces`  
Incorrect setup.

`netErrPortInUse`

`netErrInternal`

`netErrSocketAlreadyConnected`

`netErrSocketClosedByRemote`

`netErrWrongSocketType`

`netErrQuietTimeNotElapsed`

`netErrOutOfCmdBlocks`

#### Sockets Equivalent

```
int listen (int socket, int queueLen);
```

#### Comments

Sets the maximum allowable length of the queue for pending connections. This call is only applicable to stream-based (TCP/IP) sockets.

After a socket is created and bound to a local address using [NetLibSocketBind](#), a server application can call [NetLibSocketListen](#) and then [NetLibSocketAccept](#) to accept connections from remote clients.

The `queueLen` is currently quietly limited to 1 (higher values are ignored).

#### See Also

[NetLibSocketBind](#), [NetLibSocketAccept](#)

## NetLibSocketOpen

<b>Purpose</b>	Open a new socket.												
<b>Declared In</b>	NetMgr.h												
<b>Prototype</b>	<pre>NetSocketRef NetLibSocketOpen (UInt16 libRefnum, NetSocketAddrEnum domain, NetSocketTypeEnum type, Int16 protocol, Int32 timeout, Err *errP)</pre>												
<b>Parameters</b>	<table><tr><td>-&gt; libRefNum</td><td>Reference number of the net library.</td></tr><tr><td>-&gt; domain</td><td>Address domain. See <a href="#">NetSocketAddrEnum</a>.</td></tr><tr><td>-&gt; type</td><td>Desired type of connection. See <a href="#">NetSocketTypeEnum</a>.</td></tr><tr><td>-&gt; protocol</td><td>Protocol to use. This parameter is currently ignored.  For raw sockets in the netSocketAddrINET domain, specify one of the following:  netSocketProtoIPTCP netSocketProtoIPUDP netSocketProtoIPRAW  For all other socket types or for raw sockets in the raw domain, this parameter is ignored.</td></tr><tr><td>-&gt; timeout</td><td>Maximum timeout in system ticks; -1 means wait forever.</td></tr><tr><td>&lt;- errP</td><td>Contains an error code if the return value is -1.</td></tr></table>	-> libRefNum	Reference number of the net library.	-> domain	Address domain. See <a href="#">NetSocketAddrEnum</a> .	-> type	Desired type of connection. See <a href="#">NetSocketTypeEnum</a> .	-> protocol	Protocol to use. This parameter is currently ignored.  For raw sockets in the netSocketAddrINET domain, specify one of the following:  netSocketProtoIPTCP netSocketProtoIPUDP netSocketProtoIPRAW  For all other socket types or for raw sockets in the raw domain, this parameter is ignored.	-> timeout	Maximum timeout in system ticks; -1 means wait forever.	<- errP	Contains an error code if the return value is -1.
-> libRefNum	Reference number of the net library.												
-> domain	Address domain. See <a href="#">NetSocketAddrEnum</a> .												
-> type	Desired type of connection. See <a href="#">NetSocketTypeEnum</a> .												
-> protocol	Protocol to use. This parameter is currently ignored.  For raw sockets in the netSocketAddrINET domain, specify one of the following:  netSocketProtoIPTCP netSocketProtoIPUDP netSocketProtoIPRAW  For all other socket types or for raw sockets in the raw domain, this parameter is ignored.												
-> timeout	Maximum timeout in system ticks; -1 means wait forever.												
<- errP	Contains an error code if the return value is -1.												
<b>Result</b>	Returns the NetSocketRef of the opened socket or -1 if an error occurred. If an error occurred, errP contains one of the following values: <table><tr><td>0</td><td>No error.</td></tr><tr><td>netErrTimeout</td><td>Call timed out.</td></tr><tr><td>netErrNotOpen</td><td>The referenced net library has not been opened yet.</td></tr></table>	0	No error.	netErrTimeout	Call timed out.	netErrNotOpen	The referenced net library has not been opened yet.						
0	No error.												
netErrTimeout	Call timed out.												
netErrNotOpen	The referenced net library has not been opened yet.												

## Net Library

### Net Library Functions

---

netErrParamErr

netErrNoMoreSockets

netErrOutOfCmdBlocks

netErrOutOfMemory

#### **Sockets Equivalent**

```
int socket (int domain, int type, int protocol);
```

#### **Comments**

Allocates memory for a new socket and opens it.

Raw sockets are supported in Palm OS version 3.0 and higher. Two types of raw sockets are supported:

- Raw sockets in the `netSocketAddrINET` domain

In this case, you must bind the socket to an IP address using [NetLibSocketBind](#), passing a [NetSocketAddrINType](#) structure for the socket address. The port field is ignored.

For applications that use raw sockets in the INET domain, the net library checks the destination IP address of all incoming packets to see if it matches any of those raw sockets. If it does, the packet is enqueued directly into the matching socket and is **not** passed to the protocol stack.

When an application sends data through raw sockets in the IP domain, the net library packages the data into a packet and passes it directly to the interface's send routine. You are responsible for forming the entire IP header, including any necessary checksums, source and destination IP address, and so on.

- Raw sockets in the `netSocketAddrRaw` domain with no protocol

In this case, you must bind the socket to an interface using [NetLibSocketBind](#), passing a [NetSocketAddrRawType](#) structure for the socket address. The instance and creator specify which interface the caller wants to receive raw packets from.

When an interface is bound to a raw socket with no protocol, the net library places that interface into raw mode. In raw

mode, the interface passes all incoming packets, no matter what the link layer protocol, to its raw receive function.

When an application sends data through a raw socket with no protocol, the net library packages the data into a packet and passes it directly to the interface's send routine.

The interface remains in raw mode until the raw socket is closed.

**Compatibility** Raw sockets supported only in Palm OS version 3.0 and higher.

**See Also** [NetLibSocketClose](#), [NetUTCPOpen](#)

## NetLibSocketOptionGet

**Purpose** Retrieves the current value of a socket option.

**Declared In** NetMgr.h

**Prototype** `Int16 NetLibSocketOptionGet (UInt16 libRefnum, NetSocketRef socket, UInt16 level, UInt16 option, void *optValueP, UInt16 *optValueLenP, Int32 timeout, Err *errP)`

**Parameters**

-> libRefNum	Reference number of the net library.
-> socket	Descriptor for the open socket.
-> level	Level of the option, one of the NetSocketOptLevelEnum constants. See <a href="#">NetLibSocketOptionSet</a> .
-> option	One of the NetSocketOptEnum constants. See <a href="#">NetLibSocketOptionSet</a> .
<- optValueP	Pointer to variable holding new value of option.
<-> optValueLenP	Size of variable pointed to by optValueP on entry. Actual size of return value on exit.

## Net Library

### Net Library Functions

---

-> timeout           Maximum timeout in system ticks; -1 means wait forever.

<- errP               Contains an error code if the return value is -1.

**Result**           Returns 0 upon success and -1 if an error occurred. If an error occurred, errP contains one of the following values:

0                     No error.

netErrTimeout        Call timed out.

netErrNotOpen        The referenced net library has not been opened yet.

netErrParamErr

netErrSocketNotOpen

netErrUnimplemented

netErrWrongSocketType

netErrInvalidSettingSize

**Sockets Equivalent**   int getsockopt (int socket, int level, int option, const void \*optValueP, int \*optValueLenP);

**Comments**           Returns the current value of a socket option. The caller passes a pointer to a variable to hold the returned value (in optValueP) and the size of this variable (in \*optValueLenP). On exit, \*optValueP is updated with the actual size of the return value.

For all of the fixed size options (every option except netSocketOptIPOptions), \*optValueLenP is unmodified on exit and this call does its best to return the value in the caller's desired type size.

For compatibility with existing Internet applications, this call is quite flexible on the \*optValueLenP parameter. If the desired type for an option is FLAG, this call supports an \*optValueLenP of 1, 2, or 4. If the desired type for an option is int, it supports an \*optValueLenP of 2 or 4.

See [NetLibSocketOptionSet](#) for a list of available options.

**See Also**           [NetLibSocketOptionSet](#)

## NetLibSocketOptionSet

<b>Purpose</b>	Set a socket option.																
<b>Declared In</b>	NetMgr.h																
<b>Prototype</b>	<pre>Int16 NetLibSocketOptionSet (UInt16 libRefnum, NetSocketRef socket, UInt16 level, UInt16 option, void *optValueP, UInt16 optValueLen, Int32 timeout, Err *errP)</pre>																
<b>Parameters</b>	<table><tr><td>-&gt; libRefNum</td><td>Reference number of the net library.</td></tr><tr><td>-&gt; socket</td><td>Descriptor for the open socket.</td></tr><tr><td>-&gt; level</td><td>Level of the option, one of the NetSocketOptLevelEnum constants. netErrNotOpen	The referenced net library has not been opened yet.																
netErrParamErr																	
netErrSocketNotOpen																	
netErrUnimplemented																	

```
netErrWrongSocketType
netErrInvalidSettingSize
```

**Sockets Equivalent** `int setsockopt (int socketRef, int level, int option, const void *optValueP, int optValueLen);`

**Comments** Sets various options associated with a socket. The caller passes a pointer to the new option value in `optValueP` and the size of the option in `optValueLen`.

[Table 61.4](#) lists the available options.

- The Level column specifies the option level, which is one of the `netSocketOptLevelXXX` constants.
- The Option column lists the option, which is one of the `netSocketOptXXX` constants.
- The G/S column lists whether this option can be fetched with the [NetLibSocketOptionGet](#) call (G) and/or set (S) with this call.
- The type column lists the data type of the option.
- The I column specifies whether or not this option is currently implemented.

**Table 61.4 Net Library Socket Options**

<b>netSocket OptLevel...</b>	<b>netSocketOpt...</b>	<b>G/S</b>	<b>Type</b>	<b>I</b>	<b>Description</b>
IP	IPOptions	GS	UInt8 []	N	Options in IP Header

**Table 61.4 Net Library Socket Options (*continued*)**

<b>netSocket OptLevel...</b>	<b>netSocketOpt...</b>	<b>G/S</b>	<b>Type</b>	<b>I</b>	<b>Description</b>
Socket	SockNonBlocking	GS	FLAG	Y	Set non-blocking mode on/off
Socket	SockRequireErrClear	GS	FLAG	Y	Return the current error status for all subsequent socket function calls until the error is cleared.

---

For compatibility with existing Internet applications, this call is quite flexible on the `optValueLen` parameter. If the desired type for an option is `FLAG`, this call accepts an `optValueLen` of 1, 2, or 4. If the desired type for an option is `int`, it accepts an `optValueLen` of 2 or 4.

Except for the `netSocketOptSockNonBlocking` option, all options listed above have equivalents in the sockets API. The `netSocketOptSockNonBlocking` option was added to this call in the net library in order to implement the functionality of the UNIX `fcntl()` control call, which can be used to turn nonblocking mode on and off for sockets.

**See Also** [NetLibSocketOptionGet](#)

## NetLibSocketShutdown

**Purpose** Shut down a socket in one or both directions.

**Declared In** `NetMgr.h`

**Prototype** `Int16 NetLibSocketShutdown (UInt16 libRefnum, NetSocketRef socket, Int16 direction, Int32 timeout, Err *errP)`

**Parameters**

<code>-&gt; libRefNum</code>	Reference number of the net library.
<code>-&gt; socket</code>	Descriptor for the open socket.
<code>-&gt; direction</code>	Direction to shut down. One of the <code>NetSocketDirEnum</code> constants. Specifically: <code>netSocketDirInput</code> <code>netSocketDirOutput</code> <code>netSocketDirBoth</code>
<code>-&gt; timeout</code>	Maximum timeout in system ticks; -1 means wait forever.
<code>&lt;- errP</code>	Contains an error code if the return value is -1.

**Result** Returns 0 upon success and -1 if an error occurred. If an error occurred, `errP` contains one of the following values:

0	No error.
<code>netErrTimeout</code>	Call timed out.
<code>netErrNotOpen</code>	The referenced net library has not been opened yet.

## Net Library

### Net Library Functions

---

```
netErrParamErr
netErrSocketNotOpen
netErrNoMultiPktAddr
netErrOutOfCmdBlocks
```

#### Sockets Equivalent

```
int shutdown (int socket, int direction);
```

#### Comments

Shuts down communication in one or both directions on a socket. If direction is `netSocketDirInput`, the socket is marked as down in the receive direction and further read operations from it return a `netErrSocketInputShutdown` error.

## NetLibTracePrintF

#### Purpose

Store debugging information in the net library's trace buffer.

#### Declared In

`NetMgr.h`

#### Prototype

```
Err NetLibTracePrintF (UInt16 libRefNum,
const Char *formatStr, ...)
```

#### Parameters

-> `libRefNum`      Reference number of the net library.  
-> `formatStr`      A `printf` style format string.  
-> ...              Arguments to the format string.

#### Result

Returns 0 upon success or `netErrNotOpen` if the net library has not been opened.

#### Sockets Equivalent

None

#### Comments

This call is a convenient debugging tool for developing Internet applications. It stores a message into the net library's trace buffer, which can later be dumped using the [NetLibMaster](#) call. The net library's trace buffer is used to store run-time errors that the net

library encounters as well as errors and messages from network interfaces and from applications that use this call.

The `formatStr` parameter is a `printf` style format string which supports the following format specifiers:

`%d, %i, %u, %x, %s, %c`

but it does **not** support field widths, leading 0's etc.

Note that the `netTracingAppMsgs` bit of the `netSettingTraceBits` setting must be set using the call `NetLibSettingSet(...netSettingTraceBits...)`. Otherwise, this routine will do nothing.

**See Also** [NetLibTracePutS](#), [NetLibMaster](#), [NetLibSettingSet](#)

## NetLibTracePutS

<b>Purpose</b>	Store debugging information in the net library's trace buffer.
<b>Declared In</b>	<code>NetMgr.h</code>
<b>Prototype</b>	<code>Err NetLibTracePutS (UInt16 libRefNum, Char *strP)</code>
<b>Parameters</b>	<code>-&gt; libRefNum</code> Reference number of the net library. <code>-&gt; strP</code> String to store in the trace buffer.
<b>Result</b>	Returns 0 upon success or <code>netErrNotOpen</code> if the net library has not been opened.
<b>Sockets Equivalent</b>	None
<b>Comments</b>	This call is a convenient debugging tool for developing Internet applications. It will store a message into the net library's trace buffer which can later be dumped using the <a href="#">NetLibMaster</a> call. The net library's trace buffer is used to store run-time errors that the net library encounters as well as errors and messages from network interfaces and from applications that use this call.

## Net Library

### Net Library Functions

---

Note the `netTracingAppMsgs` bit of the `netSettingTraceBits` setting must be set using the `NetLibSettingSet (...netSettingTraceBits...)` call or this routine will do nothing.

**See Also** [NetLibTracePrintf](#), [NetLibMaster](#), [NetLibSettingSet](#)

## NetNToHL

**Purpose** Macro that converts a 32-bit value from network to host byte order.

**Declared In** `NetBitUtils.h`

**Prototype** `NetNToHL (x)`

**Parameters** `-> x` 32-bit value to convert.

**Result** Returns `x` in host byte order.

**Errors** none

**Sockets Equivalent** `ntohl()`

**See Also** [NetNToHS](#), [NetHToNL](#), [NetHToNS](#)

## NetNToHS

**Purpose** Macro that converts a 16-bit value from network to host byte order.

**Declared In** `NetBitUtils.h`

**Prototype** `NetNToHS (x)`

**Parameters** `-> x` 16-bit value to convert.

**Result** Returns `x` in host byte order.

**Errors**    None

**Sockets  
Equivalent**    ntohs()

**See Also**    [NetHToNL](#), [NetNToHL](#), [NetHToNS](#)

# Network Utilities

---

This chapter describes network utilities provided in the module `NetSocket.c`. These utilities are convenience functions that you can use in place of net library functions in applications that use the net library. You can find `NetSocket.c` in the folder `Libraries\Net\Src`. (On Palm OS<sup>®</sup> 3.5, `NetSocket.c` is in the folder `CodeWarrior Libraries\Comms\NetSocket\Src`.)

The include file for the functions described in this chapter is `<unix/sys_socket.h>`. This header file is not included by any other Palm<sup>™</sup> header file; you must explicitly include it in your code.

For more information on `NetSocket.c` and `sys_socket.h`, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Network Utility Functions

### NetUReadN

<b>Purpose</b>	Reads a specified number of bytes from a socket.
<b>Declared In</b>	<code>unix/sys_socket.h</code>
<b>Prototype</b>	<code>Int32 NetUReadN (NetSocketRef fd, UInt8* bufP, UInt32 numBytes)</code>
<b>Parameters</b>	<ul style="list-style-type: none"> <li>-&gt; <code>fd</code>                      Descriptor for the open socket.</li> <li>&lt;- <code>bufP</code>                      Pointer to buffer to hold received data.</li> <li>-&gt; <code>numBytes</code>                  Number of bytes to read.</li> </ul>
<b>Result</b>	Returns the number of bytes actually read. If the return value is less than 0, an error occurred.

## Network Utilities

### Network Utility Functions

---

**Comments** This function repeatedly calls [NetLibReceive](#) until numBytes have been read or until NetLibReceive returns an error.

**See Also** [NetUWriteN](#)

## NetUTCPOpen

**Purpose** Opens a TCP (streams-based) socket and connects it to a server.

**Declared In** `unix/sys_socket.h`

**Prototype** `NetSocketRef NetUTCPOpen (Char* hostName,  
Char* serviceName, Int16 port)`

**Parameters**

- > `hostName` Remote host, given either by name or by dotted decimal address.
- > `serviceName` The name of a network service. Possible services are "echo", "discard", "daytime", "qotd", "chargen", "ftp-data", "ftp", "telnet", "smtp", "time", "name", "finger", "pop2", "pop3", "nntp", "imap2". The value of this parameter is ignored if the port parameter is greater than zero.
- > `port` The number of the port to connect to on the remote host. Set port to zero to use serviceName instead.

**Result** Returns the socket descriptor of the socket that was connected, or -1 if an error occurred.

**Comments** If serviceName is given and port is less than or equal to zero, this function looks up the port number for that service on the remote host and uses it for the connection.

This function is the equivalent of calling [NetLibSocketOpen](#) and [NetLibSocketConnect](#) (or socket and connect).

---

**NOTE:** This function does not return specific reasons for failure if there is a failure. This function is not production-quality code. It is provided as a quick and dirty way of creating a connection and as sample code that can be used as a reference.

---

## NetUWriteN

- Purpose** Writes the specified number of bytes to a socket.
- Declared In** `unix/sys_socket.h`
- Prototype** `Int32 NetUWriteN (NetSocketRef fd, UInt8* bufP, UInt32 numBytes)`
- Parameters**
- > `fd` Descriptor for the open socket.
  - > `bufP` Pointer to buffer to write.
  - > `numBytes` Number of bytes to write.
- Result** Returns the number of bytes actually sent. If the return value is less than 0, an error occurred.
- Comments** This function repeatedly calls [NetLibSend](#) until `numBytes` have been written or until `NetLibSend` returns an error.
- See Also** [NetUReadN](#)

## **Network Utilities**

*Network Utility Functions*

---

# Script Plugin

---

This chapter describes the login script plugin support. You write a plugin to add to the list of available login script commands in the Network preferences panel. This chapter covers:

- [Script Plugin Data Types](#)
- [Script Plugin Constants](#)

The header file `ScriptPlugin.h` declares the API described in this chapter.

For more information on the script plugin, see the section “[Extending the Network Login Script Support](#)” on page 185 in the “[Network Communication](#)” chapter of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Script Plugin Data Types

### PluginCallbackProcType

The `PluginCallbackProcType` defines the `procP` field in [PluginExecCmdType](#).

```
typedef struct {
    ScriptPluginSelectorProcPtr selectorProcP;
} PluginCallbackProcType,
*PluginCallbackProcPtr;
```

### Field Descriptions

`selectorProcP` The address of a selector-based callback function for accessing the functionality of the network interface. Each network interface provides its own `ScriptPluginSelectorProc` function. See [ScriptPluginSelectorProc](#).

## PluginCmdPtr

The `PluginCmdPtr` type defines a pointer to a [PluginCmdType](#) structure.

```
typedef PluginCmdType * PluginCmdPtr;
```

## PluginCmdType

The `PluginCmdType` structure specifies the name of a command.

```
typedef struct {  
    Char    commandName [pluginMaxCmdNameLen + 1];  
    Boolean hasTxtStringArg;  
    UInt8   reserved;  
} PluginCmdType;
```

### Field Descriptions

<code>commandName</code>	<p>The name of the command. This string appears in the pull-down list in the Network preferences panel's script view.</p> <p>The pull-down list contains all available commands from all plugins. Make sure that your command name is unique and as short as possible.</p>
<code>hasTxtStringArg</code>	<p>true if the command takes an argument. In this case when the user selects this command, the Network preferences panel displays a field next to the command name where the user should enter the argument. This argument is passed in the <code>txtStringArg</code> field in <a href="#">PluginExecCmdType</a> when the command is to be executed.</p>
<code>reserved</code>	<p>Reserved for future use.</p>

## PluginExecCmdType

The `PluginExecCmdType` structure defines the parameter block for the `scptLaunchCmdExecuteCmd` launch code. This structure specifies which command is to be executed and provides any necessary arguments for the command. Your plugin should respond by executing the command.

```
typedef struct {
    Char    commandName [pluginMaxCmdNameLen + 1];
    Char    txtStringArg
            [pluginMaxLenTxtStringArg +
1];
    PluginCallbackProcPtr procP;
    void *  handle;
} PluginExecCmdType, *PluginExecCmdPtr;
```

### Field Descriptions

<code>commandName</code>	The command's name. This is the string that appears in the pull-down list in the script view of the Network preferences panel.
<code>txtStringArg</code>	If the command takes an argument, this field provides the argument as a string. A <code>NULL</code> value means either that the user did not provide a value, or that you didn't specify that the command takes an argument.
<code>procP</code>	A pointer to a <a href="#">PluginCallbackProcType</a> structure, which identifies the network interface function that the plugin can use to execute the command.
<code>handle</code>	Handle to information specific to a particular connection. You must pass this value when you call the function pointed to by <code>procP</code> .

## Script Plugin

### Script Plugin Data Types

---

## PluginInfoPtr

The `PluginInfoPtr` type defines a pointer to a [PluginInfoType](#) structure.

```
typedef PluginInfoType * PluginInfoPtr;
```

## PluginInfoType

The `PluginInfoType` structure is the parameter block for the `scptLaunchCmdListCmds` launch code. When your plugin receives the launch code, the `PluginInfoType` structure is empty. Your plugin should fill in the `PluginInfoType` and return it. The system uses the information returned to construct the pull-down list of available script commands and build a table of which plugin will execute which script command.

```
typedef struct {
    Char    pluginName[pluginMaxModuleNameLen + 1];
    UInt16  numOfCommands;
    PluginCmdType  command[pluginMaxNumOfCmds];
} PluginInfoType;
```

### Field Descriptions

<code>pluginName</code>	A name that the system can use to identify your plugin. This is typically the same name you give the PRC file.
<code>numOfCommands</code>	The number of commands that your plugin defines. The maximum allowed is <code>pluginMaxNumOfCmds</code> .
<code>command</code>	An array of <a href="#">PluginCmdType</a> structures that provide information about the commands that your plugin defines.

## ScriptPluginLaunchCodesEnum

The `ScriptPluginLaunchCodesEnum` defines the launch codes for the script plugin. Your script plugin's [PilotMain](#) function should respond to the launch codes defined in this enum.

```
typedef enum {
    scptLaunchCmdDoNothing =
        sysAppLaunchCmdCustomBase,
    scptLaunchCmdListCmds,
    scptLaunchCmdExecuteCmd
} ScriptPluginLaunchCodesEnum;
```

### Value Descriptions

<code>scptLaunchCmdDoNothing</code>	This launch code is a no-op supplied only to provide a beginning value for the script plugin launch codes. It is not necessary to respond to this launch code.
<code>scptLaunchCmdListCmds</code>	Provide information about the commands that your plugin executes. See <a href="#">PluginInfoType</a> .
<code>scptLaunchCmdExecuteCmd</code>	Execute the specified command.  This launch code is received when the system is executing a user's login script during a network connection attempt. Your plugin should respond by executing the command provided in the <a href="#">PluginExecCmdType</a> parameter block.

## Script Plugin Constants

### Command Constants

The following constants identify the available commands that the network interface can perform for you. These commands are building blocks that you use to create your own script commands. To perform one of these tasks, pass the constant value as an argument to the network interface's callback function ([ScriptPluginSelectorProc](#)).

---

Constant	Value	Description
<code>pluginNetLibDoNothing</code>	0	For debugging purposes.
<code>pluginNetLibReadBytes</code>	1	Read the specified number of bytes from the open connection.
<code>pluginNetLibWriteBytes</code>	2	Write the specified number of bytes to the open connection.
<code>pluginNetLibGetUserName</code>	3	Get the user name from the network service profile.
<code>pluginNetLibGetUserPwd</code>	4	Get the user's password from the network service profile.
<code>pluginNetLibCheckCancelStatus</code>	5	Check to see if the user canceled the connection.
<code>pluginNetLibPromptUser</code>	6	Prompt the user for input.
<code>pluginNetLibConnLog</code>	7	Write a string to the network service's connection log.
<code>pluginNetLibCallUIProc</code>	8	Have the network interface call a function in your plugin that displays UI.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
		Use this command if you need to display a more complicated user interface than the simple user prompt that the network interface provides.
pluginNetLibGetSerLibRefNum	9	Obtain the serial library's reference number. You need the reference number to perform any serial library commands, which you might need to perform more complex work with the connection port.

---

## Size Constants

The following table lists constants that control the size of strings in your plugin and the size of the plugin itself.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
pluginMaxCmdNameLen	15	The maximum length for the command's name, not including the terminating null character. This is the string displayed to the user in the pull-down menu.
pluginMaxModuleNameLen	15	The maximum length for the plugin's name (not including the terminating null character), which is typically the name of the PRC file as well.
pluginMaxNumOfCmds	10	The maximum number of commands that your plugin can define.
pluginMaxLenTxtStringArg	63	The maximum length of the argument that each command can take, not including the terminating null character.

---

## Script Plugin Functions

### ScriptPluginSelectorProc

<b>Purpose</b>	A function provided by the network interface for the purpose of performing script commands.	
<b>Declared In</b>	ScriptPlugin.h	
<b>Prototype</b>	Err (*ScriptPluginSelectorProcPtr) (void *handle, UInt16 command, void *dataBufferP, UInt16 *sizeP, UInt16 *dataTimeoutP, void *procAddrP);	
<b>Parameters</b>	-> handle	Handle to information specific to a particular connection.
	-> command	The command to be executed. See " <a href="#">Command Constants</a> " for a list of possible values. The rest of the parameters to this callback function are interpreted differently based on the value of the command parameter. See the table in the "Comments" section for specifics.
	<-> dataBufferP	A pointer to arguments to pass to the command or a pointer to data returned by the command. See the "Comments" section below.
	<-> sizeP	The size of dataBufferP.
	-> dataTimeoutP	Number of seconds to wait for the command to execute. 0 means wait forever. Applies only to commands that request information from the network.

-> `procAddrP`      Pointer to a user interface callback function that the network interface should call to complete the function. Used only by `pluginNetLibCallUIProc`. This function should take one argument of the same type that you pass to `dataBufferP` and should return `void`.

**Result**      Returns 0 upon success, or an error condition upon failure. If an error condition is returned, your plugin should stop processing and return the error condition from its [PilotMain](#).

**Comments**      When your plugin receives the `sctpLaunchCmdExecuteCmd` launch code, the parameter block contains the command's name, its text string argument (if any), and a pointer to the network interface's callback function. You should use this callback function any time you need to communicate with the network library, the user, or the host computer during execution of your command.

The callback function takes as arguments the handle to information about this connection (which is also passed in the launch code's parameter block), and the command that the service should execute. The rest of the parameters are interpreted differently based on what the value the command argument is. See the table below.

<b>pluginNetLib</b>	<b>dataBufferP</b>	<b>sizeP</b>	<b>dataTimeOutP</b>	<b>procAddrP</b>
<code>DoNothing</code>	N/A	N/A	N/A	N/A
<code>ReadBytes</code>	On return, contains the bytes that were read.	On input, contains the number of bytes to read.  On return, contains the number of bytes actually read.	Number of seconds to wait before timing out the operation.	N/A

## Script Plugin

### Script Plugin Functions

---

<b>pluginNetLib</b>	<b>dataBufferP</b>	<b>sizeP</b>	<b>dataTimeOutP</b>	<b>procAddrP</b>
WriteBytes	On input, contains the data to send.	On input, contains the number of bytes to send.  On return, contains the number of bytes actually sent.	Number of seconds to wait for a response before canceling.	N/A
UserName	On return, contains the user's name	On return, contains the size of the string pointed to by dataBufferP.	N/A	N/A
UserPwd	On return, contains the user's password.	On return, contains the size of the string pointed to by dataBufferP.	N/A	N/A
CheckCancelStatus	On return, the Boolean value true if the user canceled the command, false otherwise.	Size of Boolean.	N/A	N/A
PromptUser	On input, the prompt to display.  On return, the text that the user entered.	On input and on return, the size of the string pointed to by dataBufferP.	N/A	N/A

<b>pluginNetLib</b>	<b>dataBufferP</b>	<b>sizeP</b>	<b>dataTimeOutP</b>	<b>procAddrP</b>
ConnLog	The string that should be written to the log.	N/A	N/A	N/A
CallUIProc	A pointer to a structure to pass to your callback function as a parameter. This structure should contain a handle to the form to be displayed, plus any other necessary information.	N/A	N/A	A pointer to a function in your plugin that displays the form.
GetSerLib RefNum	On return, contains the serial library's reference number.	N/A	N/A	N/A

---

## **Script Plugin**

### *Script Plugin Functions*

---

# Virtual Drivers

---

This chapter provides reference material for the Serial Manager virtual device driver API:

- [Driver Data Structures](#)
- [Driver Constants](#)
- [Virtual Driver-Defined Functions](#)
- [Serial Manager Queue Functions](#)

The header files `SerialVdrv.h` and `SerialDrv.h` declare the virtual driver API. For more information on writing device drivers for the Serial Manager, see section “[Writing a Virtual Device Driver](#)” on page 114 in the “[Serial Communication](#)” chapter of *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Driver Data Structures

### DrvInfoType

The `DrvInfoType` structure defines information about the serial hardware. It is passed to and filled in by the [DrvEntryPointProcPtr](#) for a virtual driver.

```
typedef struct {
    UInt32 drvID;
    UInt32 drvVersion;
    UInt32 maxBaudRate;
    UInt32 handshakeThreshold;
    UInt32 portFlags;
    const Char *portDesc;
    DrvIRQEnum irqType;
    UInt8 multipleEnumerations;
    UInt32 dbCreator;
} DrvInfoType;
```

**Value Descriptions**

<code>drvID</code>	4-character creator type, such as 'u328'.
<code>drvVersion</code>	Version of code that works for this hardware. See <a href="#">Driver Version Constants</a> .
<code>maxBaudRate</code>	Maximum baud rate supported by this hardware.
<code>handshakeThreshold</code>	Baud rate at which the use of hardware handshaking is necessary.
<code>portFlags</code>	Bit flags denoting features of this hardware. The flags are described in <a href="#">Port Feature Constants</a> .
<code>portDesc</code>	Pointer to null-terminated string describing this hardware. This string appears in the Connection panel to describe the port to the user (only if the <code>portCncMgrVisible</code> bit in <code>portFlags</code> is set). Can be NULL if the driver contains a resource (of type 'tSTR' and id <code>kPortDescStrID</code> ) that supplies this string.
<code>irqType</code>	IRQ line being used for this hardware. For a virtual driver, specify <code>drvIRQNone</code> .
<code>multipleEnumerations</code>	The number of entries in the driver table required for this driver. If 0, the driver has a single entry.
<code>dbCreator</code>	Creator ID of the database containing this driver.

**Compatibility** The `multipleEnumerations` and `dbCreator` fields are only defined if [New Serial Manager Feature Set Version 2](#) is present.

## DrvRcvQType

The `DrvRcvQType` structure defines the virtual driver receive buffer and function pointers to functions that access and save data to the buffer. A pointer to this structure is passed to the [VdrvOpenProcPtr](#) function. The `DrvRHWRcvQPtr` type defines a pointer to a `DrvRcvQType` structure.

```
typedef struct DrvRcvQType {
    void *rcvQ;
    WriteByteProcPtr qWriteByte;
    WriteBlockProcPtr qWriteBlock;
    GetSizeProcPtr qGetSize;
    GetSpaceProcPtr qGetSpace;
    SignalCheckPtr qSignalCheck;
} DrvRcvQType;

typedef DrvRcvQType *DrvRHWRcvQPtr;
```

### Value Descriptions

<code>rcvQ</code>	Pointer to the receive buffer.
<code>qWriteByte</code>	Function pointer to a function that the virtual driver can use to write one byte to the Serial Manager's receive queue. See the <a href="#">WriteByteProcPtr</a> function.
<code>qWriteBlock</code>	Function pointer to a function that the virtual driver can use to write a block of bytes to the Serial Manager's receive queue. See the <a href="#">WriteBlockProcPtr</a> function.
<code>qGetSize</code>	Function pointer to a function that the virtual driver can use to get the total size of the Serial Manager's receive queue. See the <a href="#">GetSizeProcPtr</a> function.

qGetSpace	Function pointer to a function that the virtual driver can use to get the available space in the Serial Manager's receive queue. See the <a href="#">GetSpaceProcPtr</a> function.
qSignalCheck	Function pointer to a function that the virtual driver can use to perform a signal check for the Serial Manager's receive queue. See the <a href="#">SignalCheckPtr</a> function.

**Compatibility** The qSignalCheck field is only defined if [New Serial Manager Feature Set Version 2](#) is present.

## DrvRStatusEnum

The DrvRStatusEnum enumerated type specifies serial status bit flags. Return these enumerated types from the [VdrvStatusProcPtr](#) call.

```
typedef enum DrvRStatusEnum {
    drvRStatusCtsOn = 0x0001,
    drvRStatusRtsOn = 0x0002,
    drvRStatusDsrOn = 0x0004,
    drvRStatusTxFifoFull = 0x0008,
    drvRStatusTxFifoEmpty = 0x0010,
    drvRStatusBreakAsserted = 0x0020,
    drvRStatusDataReady = 0x0040,
    drvRStatusLineErr = 0x0080
} DrvRStatusEnum;
```

### Value Descriptions

drvRStatusCtsOn	Set if CTS line is active.
drvRStatusRtsOn	Set if RTS line is active.
drvRStatusDsrOn	Set if DSR is on.
drvRStatusTxFifoFull	Set if transmit FIFO is full; cleared if FIFO has space.
drvRStatusTxFifoEmpty	Set if transmit FIFO is empty.

<code>drvStatusBreakAsserted</code>	Set if sending break characters is enabled.
<code>drvStatusDataReady</code>	Used by debugger only.
<code>drvStatusLineErr</code>	Used by debugger only.

## SrmRcvQType

The `SrmRcvQType` structure defines the Serial Manager receive queue. This queue is passed as a parameter to the virtual driver.

```
typedef struct SrmRcvQType {
    UInt32 qStart;
    UInt32 qEnd;
    UInt32 qSize;
    UInt8 *qData;
    void *qPort;
} SrmRcvQType;
```

### Field Descriptions

<code>qStart</code>	The start of the queue.
<code>qEnd</code>	The end of the queue.
<code>qSize</code>	The size of the queue.
<code>qData</code>	The data currently in the queue.
<code>qPort</code>	A pointer to the current foreground port.

**Compatibility** The `SrmRcvQType` structure was previously a private structure. It is declared publicly if [New Serial Manager Feature Set Version 2](#) is present.

## VdrvAPIType

The `VdrvAPIType` structure defines function pointers to the required virtual driver functions. When passed a pointer to this structure in the `DrvEntryPointProcPtr` function, that function must fill in the pointers to the virtual driver functions appropriately.

```
typedef struct {
    VdrvOpenProcPtr drvOpen;
    VdrvCloseProcPtr drvClose;
    VdrvControlProcPtr drvControl;
    VdrvStatusProcPtr drvStatus;
    VdrvReadProcPtr drvRead;
    VdrvWriteProcPtr drvWrite;
    VdrvOpenProcV4Ptr drvOpenV4;
    VdrvControlCustomProcPtr drvControlCustom;
} VdrvAPIType;
```

### Value Descriptions

<code>drvOpen</code>	Pointer to the driver open function.
<code>drvClose</code>	Pointer to the driver close function.
<code>drvControl</code>	Pointer to the driver control function.
<code>drvStatus</code>	Pointer to the driver status function.
<code>drvRead</code>	Pointer to the driver read function.
<code>drvWrite</code>	Pointer to the driver write function.
<code>drvOpenV4</code>	Pointer to the driver open function for <a href="#">New Serial Manager Feature Set Version 2</a> .
<code>drvControlCustom</code>	Pointer to the driver custom control function.

**Compatibility** `drvOpenV4` and `drvControlCustom` are declared if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

### VdrvConfigType

The `VdrvConfigType` structure specifies parameters for opening a serial port. This structure is passed as a parameter to [VdrvOpenProcV4Ptr](#).

```
typedef struct VdrvConfigType {
    UInt32 baud;
    UInt32 drvId;
```

```
    UInt32 function;
    MemPtr  drvrDataP;
    UInt16  drvrDataSize;
    UInt32  sysReserved1;
    UInt32  sysReserved2;
} VdrvConfigType;
```

### Field Descriptions

baud	Baud rate at which to open the connection. Serial drivers that do not require baud rates ignore this field.
drvrPid	Creator ID of the application or library that is using the Serial Manager.
function	The reason why the port was opened. Specify the creator ID of the application that is opening the port or one of the following values:  serFncUndefined Undefined function. This is the default value for this field.  serFncPPPSession The connection is to be used for the PPP interface.  serFncSLIPSession The connection is to be used for the SLIP session.  serFncDebugger The connection is to be used for a debugging session.  serFncHotSync The connection is to be used for a HotSync operation.  serFncConsole The connection is to the debugging console.  serFncTelephony The connection is to the telephony library.

The `function` field is used by protocols such as USB and Bluetooth that perform different setup tasks based on which type of application is using them. RS-232 drivers ignore this parameter.

<code>drvDataP</code>	Pointer to a driver-specific data block.
<code>drvDataSize</code>	The size of the data block pointed to by <code>drvDataP</code> .
<code>sysReserved1</code>	Reserved for future use.
<code>sysReserved2</code>	Reserved for future use.

**Compatibility** This structure is only defined if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## VdrvCtlOpCodeEnum

The `VdrvCtlOpCodeEnum` enumerated type specifies a serial control operation. You should handle each of these constants when passed for the `controlCode` parameter to the [VdrvControlProcPtr](#) call.

```
typedef enum VdrvCtlOpCodeEnum {
    vdrvOpCodeNoOp = 0,
    vdrvOpCodeSetBaudRate = 0x1000,
    vdrvOpCodeSetSettingsFlags,
    vdrvOpCodeSetCtsTimeout,
    vdrvOpCodeClearErr,
    vdrvOpCodeSetSleepMode,
    vdrvOpCodeSetWakeupMode,
    vdrvOpCodeFIFOCount,
    vdrvOpCodeStartBreak,
    vdrvOpCodeStopBreak,
    vdrvOpCodeStartLoopback,
    vdrvOpCodeStopLoopback,
    vdrvOpCodeFlushTxFIFO,
    vdrvOpCodeFlushRxFIFO,
    vdrvOpCodeSendBufferedData,
    vdrvOpCodeRcvCheckIdle,
    vdrvOpCodeEmuSetBlockingHook,
```

```
vdrvOpCodeGetOptTransmitSize,  
vdrvOpCodeGetMaxRcvBlockSize,  
vdrvOpCodeNotifyBytesReadFromQ,  
vdrvOpCodeSetDTRAsserted,  
vdrvOpCodeGetDTRAsserted,  
vdrvOpCodeWaitForConfiguration,  
vdrvOpCodeGetUSBDeviceDescriptor,  
vdrvOpCodeGetUSBConfigDescriptor,  
vdrvOpCodeEnableIRDA,  
vdrvOpCodeDisableIRDA,  
vdrvOpCodeEnableUART,  
vdrvOpCodeDisableUART,  
vdrvOpCodeRxEnable,  
vdrvOpCodeRxDisable,  
vdrvOpCodeLineEnable,  
vdrvOpCodeEnableUARTInterrupts,  
vdrvOpCodeDisableUARTInterrupts,  
vdrvOpCodeSetReceiveQueue,  
vdrvOpCodeSaveState,  
vdrvOpCodeRestoreState,  
vdrvOpCodeSetYieldPortCallback,  
vdrvOpCodesetYieldPortRefCon,  
vdrvOpCodeUserDef = 0x2000,  
vdrvOpCodeSystem = 0x7000,  
vdrvOpCodeCustom = 0x8000  
} VdrvCtlOpCodeEnum;
```

### Value Descriptions

<code>vdrvOpCodeSetBaudRate</code>	Sets the baud rate.
<code>vdrvOpCodeSetSettingsFlags</code>	Sets the data transmission options. The bit flags are described in <a href="#">Serial Settings Constants</a> .
<code>vdrvOpCodeSetCtsTimeout</code>	Hardware handshake timeout.
<code>vdrvOpCodeClearErr</code>	Clears the hardware error state.
<code>vdrvOpCodeSetSleepMode</code>	Putts the port in sleep mode (not typically used for virtual drivers).

## Virtual Drivers

### *Driver Data Structures*

---

<code>vdvrOpCodeSetWakeupMode</code>	Wakes up the port from sleep mode (not typically used for virtual drivers).
<code>vdvrOpCodeFIFOCount</code>	Returns the number of bytes currently in the FIFO (or best estimate).
<code>vdvrOpCodeStartBreak</code>	Sends a break character or enables the sending of break characters.
<code>vdvrOpCodeStopBreak</code>	Stops sending break characters.
<code>vdvrOpCodeStartLoopback</code>	Starts loopback mode (not typically used for virtual drivers).
<code>vdvrOpCodeStopLoopback</code>	Stops loopback mode (not typically used for virtual drivers).
<code>vdrvOpCodeFlushTxFIFO</code>	Flushes the contents of the transmit FIFO.
<code>vdrvOpCodeFlushRxFIFO</code>	Flushes the contents of the receive FIFO.
<code>vdrvOpCodeSendBufferedData</code>	Notifies virtual device to send any buffered data it has not emptied from its internal buffers.
<code>vdrvOpCodeRcvCheckIdle</code>	Called periodically to allow the virtual device time to check if there is data to be received. Because virtual devices execute in the same thread as applications, they can be prevented from handling notifications of received data.
<code>vdrvOpCodeEmuSetBlockingHook</code>	Special op code for the Simulator.
<code>vdrvOpCodeGetOptTransmitSize</code>	Returns the optimum buffer size for sending data or returns 0 to specify any buffer size is acceptable.
<code>vdrvOpCodeGetMaxRcvBlockSize</code>	Returns the maximum receive block size that the Serial Manager should request from the virtual device. Can be used to implement flow control.

<code>vdrvOpCodeNotifyBytesReadFromQ</code>	Tells the virtual device that some number of bytes have been read from the receive queue by the client application. Can be used to implement flow control.
<code>vdrvOpCodeSetDTRAsserted</code>	Asserts or de-asserts the DTR signal.
<code>vdrvOpCodeGetDTRAsserted</code>	Gets the status of the DTR signal.
<code>vdrvOpCodeWaitForConfiguration</code>	Waits for USB enumeration to complete. Called from the send and receive functions of the Serial Manager. The driver should have a timeout for how long it waits for enumeration to complete. The driver should return with no error if enumeration has already occurred or has occurred within the driver's timeout. If the enumeration has not occurred within the driver's timeout, the driver should return <code>serErrTimeOut</code> .
<code>vdrvOpCodeGetUSBDeviceDescriptor</code>	Retrieves the device descriptor of a USB driver. Used to gather information about the device's capabilities. Implementation of this op code is optional. If the driver chooses to implement this op code, then the driver should return a pointer to the device descriptor. A driver that chooses not to implement this op code should return <code>serErrNotSupported</code> .
<code>vdrvOpCodeGetUSBConfigDescriptor</code>	Retrieves the configuration descriptor of a USB driver. Used to gather information about the device's capabilities. Implementation of this op code is optional. If the driver chooses to implement this op code, then the driver should return a pointer to the device descriptor. A driver that chooses not to implement this op code should return <code>serErrNotSupported</code> .
<code>vdrvOpCodeEnableIRDA</code>	Enable the IrDA mode and power up the IR line drivers.

## Virtual Drivers

### *Driver Data Structures*

---

<code>vdrvOpCodeDisableIRDA</code>	Disable the IrDA mode and disable the IR line drivers.
<code>vdrvOpCodeEnableUART</code>	Powers up the UART and the line drivers.
<code>vdrvOpCodeDisableUART</code>	Powers down the UART and the line drivers.
<code>vdrvOpCodeRxEnable</code>	Enables the receive FIFO, enables UART interrupts, and does whatever else is necessary to allow the UART to receive data.
<code>vdrvOpCodeRxDisable</code>	Disables the receive FIFO and UART interrupts and does whatever is needed to prevent the UART from receiving data.
<code>vdrvOpCodeLineEnable</code>	Enables the main serial line driver for the UART.
<code>vdrvOpCodeEnableUARTInterrupts</code>	Enables the appropriate UART receive interrupts.
<code>vdrvOpCodeDisableUARTInterrupts</code>	Disables all UART interrupts.
<code>vdrvOpCodeSetReceiveQueue</code>	This op code is used by the Serial Manager to set the driver's receive queue. This control code is called when a driver that has previously been opened as a background port is opened as a fully open bidirectional port.
<code>vdrvOpCodeSaveState</code>	Invoked when this port is yielded. This is a hook for the driver to save any current state.
<code>vdrvOpCodeRestoreState</code>	Invoked when the foreground port is closed and this port can become the foreground port.
<code>vdrvOpCodeSetYieldPortCallback</code>	Set the function to be called if the Serial Manager attempts to open another port when this one is open. This op code is for system use only.

vdrvOpCodeSetYieldPortRefCon	Data to pass to the yield port callback function. System use only.
vdvrOpCodeUserDef	User defined function invoked through <a href="#">SrmControl</a> .
vdrvOpCodeSystem	Reserves op codes between 0x7000 and 0x8000 for system use.
vdrvOpCodeCustom	Reserves op codes greater than 0x8000 for driver-specific use.

**Compatibility** The op codes starting at `vdrvOpCodeWaitForConfiguration` are defined only if [New Serial Manager Feature Set Version 2](#) is present. The op codes for yieldable ports and custom operations are defined only if both [4.0 New Feature Set](#) is present as well.

## Driver Constants

### Driver Version Constants

The driver version constants specify which version of the driver API is implemented by this driver. The [DrvEntryPointProcPtr](#) function passes this value back to the Serial Manager in the `drvvrVersion` field of the [DrvvrInfoType](#) function.

Constant	Value	Description
<code>kDrvvrVersion</code>	4	The latest version of the API.
<code>kDrvvrVersion3</code>	3	The version of the driver API that corresponds to <a href="#">New Serial Manager Feature Set Version 1</a> (which ships with roughly Palm OS® 3.3 up to Palm OS 4.0).
<code>kDrvvrVersion4</code>	4	The version of the driver API that corresponds to <a href="#">New Serial Manager Feature Set Version 2</a> (which ships with roughly Palm OS 4.0 and higher).

## Virtual Drivers

### *Driver Constants*

---

## Port Feature Constants

The port feature constants are flags that describe serial hardware capabilities.

Constant	Value	Description
portPhysicalPort	0x00000001	Should be set for a physical port, unset for a virtual port.
portBkgndModeSupported	0x00000002	Denotes that this port can be used for background ports. This flag is only applicable to virtual drivers. Background mode support is implied on physical drivers.
portRS232Capable	0x00000004	Set if this hardware has an RS-232 port.
portIRDACapable	0x00000008	Set if this hardware has an IR port and supports IrDA mode.
portCradlePort	0x00000010	Set if this hardware controls the cradle port.
portExternalPort	0x00000020	Set if this hardware port is external or on a memory card.
portModemPort	0x00000040	Set if this hardware communicates with a modem.
portCncMgrVisible	0x00000080	Set if this serial port's name is to be displayed in the Connection panel.
portConsolePort	0x00000100	Denotes this hardware controls the console port.
portUSBCapable	0x00000200	Set if this hardware has a USB port.
portPrivateUse	0x00001000	Set if this driver is for special software and not general applications.

---

**Compatibility**    USB support is only available if [New Serial Manager Feature Set Version 2](#) is present.

## Virtual Driver-Defined Functions

The functions in this section must be defined by your virtual driver.

### **DrvEntryPointProcPtr**

<b>Purpose</b>	Entry point for the virtual driver.				
<b>Declared In</b>	<code>SerialDrvr.h</code>				
<b>Prototype</b>	<pre>Err (*DrvEntryPointProcPtr) (DrvrEntryOpCodeEnum opCode, void *uartData)</pre>				
<b>Parameters</b>	<table><tr><td><code>-&gt; opCode</code></td><td>Entry function code.</td></tr><tr><td><code>&lt;-&gt; uartData</code></td><td>Pointer to data specific to <code>opCode</code>.</td></tr></table>	<code>-&gt; opCode</code>	Entry function code.	<code>&lt;-&gt; uartData</code>	Pointer to data specific to <code>opCode</code> .
<code>-&gt; opCode</code>	Entry function code.				
<code>&lt;-&gt; uartData</code>	Pointer to data specific to <code>opCode</code> .				
<b>Result</b>	<table><tr><td><code>errNone</code></td><td>No error.</td></tr><tr><td><code>-1</code></td><td>The op code is invalid or the hardware could not be found.</td></tr></table>	<code>errNone</code>	No error.	<code>-1</code>	The op code is invalid or the hardware could not be found.
<code>errNone</code>	No error.				
<code>-1</code>	The op code is invalid or the hardware could not be found.				
<b>Comments</b>	<p>This function's purpose is based on the value of the <code>opCode</code> parameter. The three possible codes are <code>drvEntryGetUartFeatures</code>, <code>drvEntryGetDrvrFuncs</code>, and <code>drvEntryGetUartFtrsNEntries</code>.</p> <p><code>DrvEntryPoint</code> is called with the <code>drvEntryGetUartFeatures</code> code when the Serial Manager is installed into the system at boot time and is looking for all installed drivers. When this op code is set, the <code>uartData</code> pointer points to a <a href="#">DrvrInfoType</a> structure. This function does not allocate the structure, it just fills in the fields with information.</p> <p>This function should check to make sure the associated serial device can operate under the current OS and system settings. If the hardware cannot be found, the function should leave the <code>DrvrInfoType</code> struct untouched and return a <code>-1</code> error.</p> <p>The driver needs to supply a string that describes the port it manages. This string is displayed to the user in the Connection panel and is returned by the <a href="#">SrmGetDeviceInfo</a> function. To set</p>				

this string, copy it into the `portDesc` field of the `DrvInfoType` structure. Alternatively, you can supply this string in a driver resource of type 'tSTR' and id `kPortDescStrID`.

If the `DrvInfoType` structure has a positive value in the `multipleEnumerations` field upon return, the Serial Manager defines one port for each entry in the driver table. The `DrvEntryPoint` function is called again, this time with the `drvEntryGetUartFtrsNEntries` code. The `uartData` pointer points to a new `DrvInfoType` structure whose `multipleEnumerations` field indicates which port is to be defined. The function should supply all information specific to this port.

`DrvEntryPoint` is called with the `drvEntryGetDrvFuncs` code when a virtual port is opened. The `uartData` pointer points to a [VdrvAPIType](#) structure and `DrvEntryPoint` must fill in the fields of this structure with appropriate function pointers.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

The `drvEntryGetUartFtrsNEntries` is only supported if [New Serial Manager Feature Set Version 2](#) is present. This function is fully backwards compatible. Passing 0 for the `multipleEnumerations` field defines a single port for the driver.

## VdrvCloseProcPtr

<b>Purpose</b>	Handles all activities needed to close the virtual device.	
<b>Declared In</b>	<code>SerialDrv.h</code>	
<b>Prototype</b>	<code>Err (*VdrvCloseProcPtr) (VdrvDataPtr drvData)</code>	
<b>Parameters</b>	<code>-&gt; drvData</code>	Pointer to the driver's private global area.
<b>Result</b>	<code>errNone</code>	No error.

## Virtual Drivers

### Virtual Driver-Defined Functions

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## VdrvControlProcPtr

**Purpose** Extends the `SrmControl` function to the level of the virtual device.

**Declared In** `SerialDrvr.h`

**Prototype** `Err (*VdrvControlProcPtr) (VdrvDataPtr drvData, VdrvCtlOpCodeEnum controlCode, void *controlData, UInt16 *controlDataLen)`

**Parameters**

- > `drvData` Pointer to the driver's private global area.
- > `controlCode` Control function op code. One of the op codes listed in the [VdrvCtlOpCodeEnum](#) type.
- <-> `controlData` Pointer to data for the specified control function.
- <-> `controlDataLen` Pointer to length of control data being passed in or out.

**Result**

- `errNone` No error.
- `serErrNotSupported` `controlCode` not supported.
- `serErrBadParam` `controlData` or `controlDataLen` is bad.

**Comments** This function should support the op codes listed in the [VdrvCtlOpCodeEnum](#) type. If this function does not support an op code, it must return the `serErrNotSupported` error code for that op code.

[Table 64.1](#) shows what is passed for the `controlData` and `controlDataLen` parameters for each of the control codes that use them. Control codes not listed do not use these parameters.

**Table 64.1 VDrvControlProcPtr Parameters**

vdrvOpCodeSetBaudRate	-> controlData = Pointer to Int32 (baud rate), -> controlDataLen = Pointer to sizeof (Int32).
vdrvOpCodeSetSettingsFlags	-> controlData = Pointer to UInt32 (bitfield; see <a href="#">Serial Settings Constants</a> ) -> controlDataLen = Pointer to sizeof (UInt32)
vdrvOpCodeFIFOCount	-> controlData = Pointer to Int16, which contains the number of bytes in the FIFO. -> controlDataLen = Pointer to sizeof (Int16).
vdrvOpCodeGetOptTransmitSize	<- controlData = Pointer to Int32 (buffer size), <- controlDataLen = Pointer to sizeof (Int32). Return the optimum buffer size for sending data, or 0 to specify any buffer size is acceptable.
vdrvOpCodeGetMaxRcvBlockSize	<- controlData = Pointer to Int32 (block size), <- controlDataLen = Pointer to sizeof (Int32). Return the maximum block size that the Serial Manager should request from the virtual device.
vdrvOpCodeNotifyBytesReadFromQ	-> controlData = Pointer to Int32 (number of bytes read), -> controlDataLen = Pointer to sizeof (Int32).
vdrvOpCodeSetDTRAsserted	-> controlData = Pointer to Boolean indicating whether to enable or disable DTR. -> controlDataLen = Pointer to sizeof (Boolean)

## Virtual Drivers

### Virtual Driver-Defined Functions

---

**Table 64.1 VDrvControlProcPtr Parameters (continued)**

---

vdrvOpCodeGetDTRAsserted	<- controlData = Pointer to Boolean indicating whether DTR is enabled. <- controlDataLen = Pointer to sizeof (Boolean)
vdvrOpCodeUserDef	<-> controlData = Pointer from <a href="#">SrmControl</a> (user-defined data), <-> controlDataLen = Pointer to sizeof (Int32).

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

### VdrvControlCustomProcPtr

**Purpose** Extends the SrmCustomControl function to the level of the virtual device.

**Declared In** SerialDrvr.h

**Prototype** Err (\*VdrvControlCustomProcPtr)  
(VdrvDataPtr drvData, UInt16 opCode,  
UInt32 creator, void \*controlData,  
void \*controlDataLenP)

**Parameters**

- > drvData Pointer to the driver's private global area.
- > controlCode Control function op code.
- > creator Creator ID of the driver that defines the op code. The combination of creator ID and op code uniquely identifies the operation to be performed.
- <-> controlData Pointer to data for the specified control function.

	<code>&lt;-&gt; controlDataLen</code>	Pointer to length of control data being passed in or out.
<b>Result</b>	<code>errNone</code>	No error.
	<code>serErrNotSupported</code>	<code>controlCode</code> not supported.
	<code>serErrBadParam</code>	<code>controlData</code> or <code>controlDataLen</code> is bad.
<b>Comments</b>	This function is a mechanism for a virtual driver to create control codes specific to that driver, allowing for the support of new technologies that have interfaces through the Serial Manager.	
<b>Compatibility</b>	Implemented only if both <a href="#">New Serial Manager Feature Set Version 2</a> and <a href="#">4.0 New Feature Set</a> are present.	

## VdrvOpenProcPtr

<b>Purpose</b>	Initializes the virtual device to begin communication.	
<b>Declared In</b>	<code>SerialDrvr.h</code>	
<b>Prototype</b>	<code>Err (*VdrvOpenProcPtr) (VdrvDataPtr *drvData, UInt32 baudRate, DrvrHWrcvQPtr rcvQP)</code>	
<b>Parameters</b>	<code>&lt;-&gt; drvData</code>	Pointer to a pointer to the driver's private global area (allocated by this function). A pointer to this private global area is passed to the other virtual driver functions.
	<code>-&gt; baudRate</code>	Initial baud rate setting.
	<code>-&gt; rcvQP</code>	Pointer to the driver's receive queue buffer structure. For details on the fields, see <a href="#">DrvrRcvQType</a> .
<b>Result</b>	<code>errNone</code>	No error.

## Virtual Drivers

### Virtual Driver-Defined Functions

---

**Comments** This function must allocate and initialize any global variables (and pass back a pointer to a pointer to them in `drvDataP`), do any set-up necessary for communicating with other software, and save the `rcvQP` pointer since it will need the functions and pointers to structures enclosed within to be able to save received data into the Serial Manager's receive queue.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## VdrvOpenProcV4Ptr

**Purpose** Initializes the virtual device to begin communication.

**Declared In** `SerialDvr.h`

**Prototype** `Err (*VdrvOpenProcV4Ptr) (VdrvDataPtr *drvData, VdrvConfigPtr configP, DvrHWRCvQPtr rcvQP)`

**Parameters**

<code>&lt;-&gt; drvData</code>	Pointer to a pointer to the driver's private global area (allocated by this function). A pointer to this private global area is passed to the other virtual driver functions.
<code>-&gt; configP</code>	Pointer to the configuration structure specifying the port's properties. See <a href="#">VdrvConfigType</a> .
<code>-&gt; rcvQP</code>	Pointer to the driver's receive queue buffer structure. For details on the fields, see <a href="#">DvrRcvQType</a> .

**Result** `errNone` No error.

**Comments** This function must allocate and initialize any global variables (and pass back a pointer to a pointer to them in `drvDataP`), do any set-up necessary for communicating with other software, and save the `rcvQP` pointer since it will need the functions and pointers to structures enclosed within to be able to save received data into the Serial Manager's receive queue.

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## VdrvStatusProcPtr

**Purpose** Returns virtual device status.

**Declared In** SerialDrv.h

**Prototype** UInt16 (\*VDrvStatusProcPtr) (VdrvDataPtr drvData)

**Parameters** -> drvData Pointer to the driver's private global area.

**Result** An unsigned long bitfield denoting the status of the virtual device, but only if the virtual device is emulating hardware. The individual bit flags are described in the [DrvStatusEnum](#) type.

**Comments** Generally, status is returned only to the client application using the virtual device. The Serial Manager does not use status information from virtual devices.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## VdrvWriteProcPtr

**Purpose** Writes a block of bytes.

**Declared In** SerialDrv.h

**Prototype** UInt32 (\*VdrvWriteProcPtr) (VdrvDataPtr drvDataP, void \*bufP, UInt32 size, Err \*errP)

**Parameters**

- > drvDataP Pointer to the driver's private global area.
- > bufP Pointer to buffer containing the data to be written to the virtual device.
- > size Number of bytes in the buffer bufP.

## Virtual Drivers

### Serial Manager Queue Functions

---

`<- errP` Pointer to an error code resulting from the operation. Zero is returned if there is no error.

**Result** Returns the actual number of bytes written.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## Serial Manager Queue Functions

The functions in this section are supplied by the Serial Manager to the virtual driver through the [DrvRcvQType](#) passed to the [VdrvOpenProcPtr](#) function.

### GetSizeProcPtr

**Purpose** Returns the total size of the Serial Manager's receive queue.

**Declared In** `SerialDrv.h`

**Prototype** `typedef UInt32 (*GetSizeProcPtr) (void *theQ)`

**Parameters** `-> theQ` Pointer to the receive queue.

**Result** Size in bytes of the Serial Manager's receive queue.

**Comments** This function is useful for implementing flow control.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## GetSpaceProcPtr

<b>Purpose</b>	Returns the available space in the Serial Manager's receive queue.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<code>typedef UInt32 (*GetSpaceProcPtr) (void *theQ)</code>
<b>Parameters</b>	-> <code>theQ</code> Pointer to the receive queue.
<b>Result</b>	Size in bytes of the available space in the Serial Manager's receive queue.
<b>Comments</b>	This function is useful for implementing flow control.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.

## SignalCheckPtr

<b>Purpose</b>	Check the queue to see if the semaphore needs to be signalled.
<b>Declared In</b>	<code>SerialDrvr.h</code>
<b>Prototype</b>	<code>typedef void (*SignalCheckPtr) (void *theQ, UInt16 lineErrsP)</code>
<b>Parameters</b>	-> <code>theQ</code> Pointer to the receive queue. -> <code>lineErrsP</code> Any serial line errors received should be reported here.
<b>Result</b>	Returns nothing.
<b>Comments</b>	This function signals that there is data to be received without writing anything to the receive queue. The <a href="#">WriteByteProcPtr</a> and <a href="#">WriteBlockProcPtr</a> functions also signal that there is data to be received after they have written the data to the queue.

## Virtual Drivers

### Serial Manager Queue Functions

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 2](#) is present.

## WriteBlockProcPtr

**Purpose** Writes a block of bytes to the Serial Manager's receive queue.

**Declared In** SerialDrvr.h

**Prototype**

```
typedef Err (*WriteBlockProcPtr) (void *theQ,
UInt8 *bufP, UInt16 size, UInt16 lineErrs)
```

**Parameters**

-> theQ	Pointer to the receive queue.
-> bufP	Pointer to the buffer holding bytes to be written.
-> size	Size of bufP.
-> lineErrs	Any serial line errors received should be reported here.

**Result**

errNone	No error.
serErrLineErr	There was a software overrun line error.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## WriteByteProcPtr

**Purpose** Writes one byte to the Serial Manager's receive queue.

**Declared In** SerialDrvr.h

**Prototype**

```
typedef Err (*WriteByteProcPtr) (void *theQ,
UInt8 theByte, UInt16 lineErrs)
```

**Parameters**

-> theQ	Pointer to the receive queue.
-> theByte	The byte to be written to the queue.

	-> lineErrs	Any serial line errors received should be reported here.
<b>Result</b>	errNone	No error.
	serErrLineErr	There was a software overrun line error.
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.	

## **Virtual Drivers**

### *Serial Manager Queue Functions*

---

# Serial Manager

---

This chapter provides reference material for the Serial Manager API:

- [Serial Manager Data Structures](#)
- [Serial Manager Constants](#)
- [Serial Manager Functions](#)
- [Serial Manager Application-Defined Functions](#)

The header file `SerialMgr.h` declares the Serial Manager API. The file `SystemResources.h` defines some serial port constants. For more information on the Serial Manager, see the chapter “[Serial Communication](#)” on page 89 of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Serial Manager Data Structures

### DeviceInfoType

The `DeviceInfoType` structure defines information about a serial device. This structure is returned by the [SrmGetDeviceInfo](#) function.

```
typedef struct DeviceInfoType {
    UInt32 serDevCreator;
    UInt32 serDevFtrInfo;
    UInt32 serDevMaxBaudRate;
    UInt32 serDevHandshakeBaud;
    Char *serDevPortInfoStr;
    UInt8 reserved[8];
} DeviceInfoType;
typedef DeviceInfoType *DeviceInfoPtr;
```

## Serial Manager

### Serial Manager Data Structures

---

#### Value Descriptions

<code>serDevCreator</code>	Four-character creator ID for serial driver.
<code>serDevFtrInfo</code>	Flags defining features of this serial hardware. See <a href="#">Serial Capabilities Constants</a> for a description of these flags.
<code>serDevMaxBaudRate</code>	Maximum baud rate for this device.
<code>serDevHandshakeBaud</code>	Hardware handshaking is recommended for baud rates over this rate.
<code>serDevPortInfoStr</code>	Description of serial hardware device or virtual device.

#### SrmCtlEnum

The `SrmCtlEnum` enumerated type specifies a serial control operation. Specify one of these enumerated types for the `op` parameter to the [SrmControl](#) call.

```
typedef enum SrmCtlEnum {
    srmCtlFirstReserved = 0,
    srmCtlSetBaudRate,
    srmCtlGetBaudRate,
    srmCtlSetFlags,
    srmCtlGetFlags,
    srmCtlSetCtsTimeout,
    srmCtlGetCtsTimeout,
    srmCtlStartBreak,
    srmCtlStopBreak,
    srmCtlStartLocalLoopback,
    srmCtlStopLocalLoopback,
    srmCtlIrDAEnable,
    srmCtlIrDADisable,
    srmCtlRxEnable,
    srmCtlRxDisable,
    srmCtlEmuSetBlockingHook,
    srmCtlUserDef,
```

```
    srmCtlGetOptimalTransmitSize,  
    srmCtlSetDTRAsserted,  
    srmCtlGetDTRAsserted,  
    srmCtlSetYieldPortCallback,  
    srmCtlSetYieldPortRefCon,  
    srmCtlSystemReserved = 0x7000  
    srmCtlCustom = 0x8000,  
    srmCtlLAST  
} SrmCtlEnum;
```

### Value Descriptions

<code>srmCtlSetBaudRate</code>	Sets the current baud rate for the serial hardware.
<code>srmCtlGetBaudRate</code>	Gets the current baud rate for the serial hardware.
<code>srmCtlSetFlags</code>	Sets the current flag settings for the serial hardware. Specify flags from the set described in <a href="#">Serial Settings Constants</a> .
<code>srmCtlGetFlags</code>	Gets the current flag settings for the serial hardware.
<code>srmCtlSetCtsTimeout</code>	Sets the current CTS timeout value for hardware handshaking.
<code>srmCtlGetCtsTimeout</code>	Gets the current CTS timeout value for hardware handshaking.
<code>srmCtlStartBreak</code>	Turn RS-232 break signal on. Caller is responsible for turning this signal on and off and insuring it is on long enough to generate a viable break.
<code>srmCtlStopBreak</code>	Turn RS-232 break signal off.
<code>srmCtlStartLocalLoopback</code>	Start local loopback test.
<code>srmCtlStopLocalLoopback</code>	Stop local loopback test.

## Serial Manager

### Serial Manager Data Structures

---

<code>srmCtlIrDAEnable</code>	Enable IrDA connection on this serial port. <hr/> <b>NOTE:</b> You cannot enable an IrDA connection on a VZ processor. <hr/>
<code>srmCtlIrDADisable</code>	Disable IrDA connection on this serial port.
<code>srmCtlRxEnable</code>	Enable receiver (for IrDA).
<code>srmCtlRxDisable</code>	Disable receiver (for IrDA).
<code>srmCtlEmuSetBlockingHook</code>	Set a blocking hook routine for emulation mode only. Not supported on the actual device.
<code>srmCtlUserDef</code>	<p>This is a user-defined function that third-party hardware developers can use to set or retrieve hardware-specific information from the serial driver. This op code invokes the driver's corresponding control function with its user-defined op code and the parameters are passed directly through to the serial driver. A serial driver that does not handle this function returns a <code>serErrBadParam</code> error.</p> <p>The <code>srmCtlUserDef</code> op code is superseded by defining a custom op code if <a href="#">New Serial Manager Feature Set Version 2</a> is present.</p>
<code>srmCtlGetOptimalTransmitSize</code>	Ask the port for the most efficient buffer size for transmitting data packets. This op code returns an error (buffering not necessary), 0 (buffering requested, but application can choose buffer size), or a number greater than 0 (recommended buffer size).
<code>srmCtlSetDTRAsserted</code>	Enabled or disable the DTR signal. This is not supported by all hardware.
<code>srmCtlGetDTRAsserted</code>	Ask the port whether the DTR signal is enabled or disabled.

<code>srmCtlSetYieldPortCallback</code>	Set the function to be called if the Serial Manager attempts to open another port when this one is open. This op code is for system use only.
<code>srmCtlSetYieldPortRefCon</code>	Data to pass to the yield port callback function. System use only.
<code>srmCtlSystemReserved</code>	Reserves op codes between 0x7000 and 0x8000 for system use.
<code>srmCtlCustom</code>	Reserves op codes greater than 0x8000 for driver-specific use.

**Compatibility** Custom control op codes are only supported if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## SrmOpenConfigType

The `SrmOpenConfigType` structure specifies parameters for opening a serial port. This structure is passed as a parameter to [SrmExtOpen](#).

```
typedef struct SrmOpenConfigType {
    UInt32 baud;
    UInt32 function;
    MemPtr drvDataP;
    UInt16 drvDataSize;
    UInt32 sysReserved1;
    UInt32 sysReserved2;
} SrmOpenConfigType;
```

## Serial Manager

### Serial Manager Data Structures

---

#### Field Descriptions

<code>baud</code>	Baud rate at which to open the connection. Serial drivers that do not require baud rates ignore this field.
<code>function</code>	<p>The reason why the port was opened. Specify the creator ID of the application that is opening the port or one of the following values:</p> <ul style="list-style-type: none"><li><code>serFncUndefined</code> Undefined function. This is the default value for this field.</li><li><code>serFncPPPSession</code> The connection is to be used for the PPP interface.</li><li><code>serFncSLIPSession</code> The connection is to be used for the SLIP session.</li><li><code>serFncDebugger</code> The connection is to be used for a debugging session.</li><li><code>serFncHotSync</code> The connection is to be used for a HotSync operation.</li><li><code>serFncConsole</code> The connection is to the debugging console.</li><li><code>serFncTelephony</code> The connection is to the telephony library.</li></ul> <p>The <code>function</code> field is used by protocols such as USB and Bluetooth that perform different setup tasks based on which type of application is using them. RS-232 drivers ignore this parameter.</p>
<code>drvDataP</code>	Pointer to a driver-specific data block.
<code>drvDataSize</code>	The size of the data block pointed to by <code>drvDataP</code> .

sysReserved1   Reserved for future use.

sysReserved2   Reserved for future use.

**Compatibility**   This structure is only defined if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## Serial Manager Constants

### Port Constants

When you specify the port to open in the [SrmOpen](#), [SrmOpenBackground](#), [SrmExtOpen](#), or [SrmExtOpenBackground](#) call, you can use either a logical port constant, physical port constant, or a virtual port constant, but it is highly recommended that you use a logical port constant wherever possible.

### Logical Serial Port Constants

These constants specify the logical port names.

Constant	Value	Description
serPortLocalHotSync	0x8000	The physical HotSync port. The Serial Manager automatically detects whether this port is USB or RS-232.
serPortCradlePort	0x8000	Cradle port. The Serial Manager automatically detects whether this port is USB or RS-232. Most applications should specify this as the port.
serPortIrPort	0x8001	The IR port. This is a raw IrDA port with no protocol support.
serPortConsolePort	0x8002	The debug console port, either USB or RS-232. USB is preferred where both are available.

## Serial Manager

### Serial Manager Constants

---

Constant	Value	Description
<code>serPortCradleRS232Port</code>	0x8003	Port for the RS-232 cradle. Specify this port if you want to ensure that your application uses RS-232 communications only.
<code>serPortCradleUSBPort</code>	0x8004	Port for the USB cradle. Specify this port if you want to ensure that your application uses USB communications only.

---

**Compatibility** USB ports are only supported if [New Serial Manager Feature Set Version 2](#) is present.

#### Physical Serial Port Constants

The physical port constants specify 4-character constants that reference the physical hardware of the device. Doing so is **not** recommended because the hardware they reference may not exist on a particular device.

Physical port	Value	Description
<code>sysFileCUart328</code>	'u328'	Cradle port using the 68328 UART. This port can be switched between RS232 and IrDA mode using the <a href="#">SrmControl</a> call.
<code>sysFileCUart328EZ</code>	'u8EZ'	Cradle port using the 68328EZ UART. This port can also be switched between RS232 and IrDA mode.
<code>sysFileCUart650</code>	'u650'	Specifies the IR port on the upgrade card for Palm Personal or Palm Professional devices. This gives you a raw IR port like calling <code>SrmControl</code> does, but it only exists on devices that have the upgrade card.

---

#### Virtual Serial Port Constants

The virtual port constants specify 4-character constants that identify virtual ports, simulating a hardware interface. Virtual ports are not tied to specific hardware.

Physical port	Value	Description
<code>sysFileCVirtIrComm</code>	'ircm'	A virtual serial cable over an IrDA link using the IRComm protocol. It can only be used to talk to another IRComm device.
<code>sysFileCVirtRfComm</code>	'rfcm'	RFCOMM (Bluetooth) virtual port plug-in.
<code>sysFileCBtConnectPanelHelper</code>	'btcp'	Bluetooth Connection Panel helper application.

**Compatibility** All virtual port constants other than `sysFileCVirtIrComm` are only defined if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

## Serial Capabilities Constants

The serial capabilities constant flags describe serial hardware capabilities. These flags are set in the `serDevFtrInfo` field of the [DeviceInfoType](#) structure.

Constant	Value	Description
<code>serDevCradlePort</code>	0x00000001	Serial hardware controls RS-232 serial from cradle connector of Palm device.
<code>serDevRS232Serial</code>	0x00000002	Serial hardware has RS-232 line drivers.
<code>serDevIRDACapable</code>	0x00000004	Serial hardware has IR line drivers and generates IrDA mode serial signals.
<code>serDevModemPort</code>	0x00000008	Serial hardware drives modem connection.
<code>serDevCncMgrVisible</code>	0x00000010	Serial device port name string is to be displayed in the Connection panel.

## Serial Manager

### Serial Manager Constants

---

Constant	Value	Description
serDevConsolePort	0x00000020	Serial device is the default console port.
serDevUSBCapable	0x00000040	Serial hardware controls USB serial from cradle connector of Palm device.

---

**Compatibility** USB ports are only supported if [New Serial Manager Feature Set Version 2](#) is present.

### Serial Settings Constants

The serial settings constants identify bit flags that correspond to various serial hardware settings. Use [SrmControl](#) with the op code `srmCtlSetFlags` to control which settings are used.

Constant	Value	Description
srmSettingsFlagStopBitsM	0x00000001	Mask for stop bits field
srmSettingsFlagStopBits1	0x00000000	1 stop bit (default)
srmSettingsFlagStopBits2	0x00000001	2 stop bits
srmSettingsFlagParityOnM	0x00000002	Mask for parity on
srmSettingsFlagParityEvenM	0x00000004	Mask for parity even
srmSettingsFlagXonXoffM	0x00000008	Mask for Xon/Xoff flow control (not implemented)
srmSettingsFlagRTSAutoM	0x00000010	Mask for RTS receive flow control. This is the default.
srmSettingsFlagCTSAutoM	0x00000020	Mask for CTS transmit flow control
srmSettingsFlagBitsPerCharM	0x000000C0	Mask for bits per character
srmSettingsFlagBitsPerChar5	0x00000000	5 bits per character
srmSettingsFlagBitsPerChar6	0x00000040	6 bits per character

---

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>srmSettingsFlagBitsPerChar7</code>	<code>0x00000080</code>	7 bits per character
<code>srmSettingsFlagBitsPerChar8</code>	<code>0x000000C0</code>	8 bits per character (default)
<code>srmSettingsFlagFlowControlIn</code>	<code>0x00000100</code>	<p>Protect the receive buffer from software overruns. When this flag and <code>srmSettingsFlagRTSAutoM</code> are set, which is the default case, it causes the Serial Manager to assert RTS to prevent the transmitting device from continuing to send data when the receive buffer is full. Once the application receives data from the buffer, RTS is de-asserted to allow data reception to resume.</p> <p>Note that this feature effectively prevents software overrun line errors but may also cause CTS timeouts on the transmitting device if the RTS line is asserted longer than the defined CTS timeout value.</p>
<code>srmSettingsFlagRTSInactive</code>	<code>0x00000200</code>	<p>If this flag is set and <code>srmSettingsFlagRTSAutoM</code> is not set, RTS is held in the inactive (flow off) state forever.</p>

---

## Serial Manager

### Serial Manager Constants

---

#### Status Constants

The status constants identify bit flags that correspond to the status of serial signals. They can be returned by the [SrmGetStatus](#) function.

Constant	Value	Description
<code>srmStatusCtsOn</code>	0x00000001	CTS line is active.
<code>srmStatusRtsOn</code>	0x00000002	RTS line is active.
<code>srmStatusDsrOn</code>	0x00000004	DSR line is active.
<code>srmStatusBreakSigOn</code>	0x00000008	Break signal is active.

---

#### Line Error Constants

The line error constants identify bit flags that correspond to the line errors that may occur on the port. They can be returned by the [SrmGetStatus](#) function.

Constant	Value	Description
<code>serLineErrorParity</code>	0x0001	Parity error
<code>serLineErrorHWOverrun</code>	0x0002	Hardware overrun
<code>serLineErrorFraming</code>	0x0004	Framing error
<code>serLineErrorBreak</code>	0x0008	Break signal asserted
<code>serLineErrorHShake</code>	0x0010	Line handshake error
<code>serLineErrorSWOverrun</code>	0x0020	Software overrun
<code>serLineErrorCarrierLost</code>	0x0040	Carrier detect signal dropped

---

## Serial Manager Functions

### SrmClearErr

<b>Purpose</b>	Clears the port of any line errors.	
<b>Declared In</b>	SerialMgr.h	
<b>Prototype</b>	Err SrmClearErr (UInt16 portId)	
<b>Parameters</b>	-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
<b>Result</b>	This function returns the following error codes: errNone           No error. serErrNotSupported           The port is not the foreground port.	
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.	

### SrmClose

<b>Purpose</b>	Closes a serial port and makes it available to other applications, regardless of whether the port is a foreground or background port.	
<b>Declared In</b>	SerialMgr.h	
<b>Prototype</b>	Err SrmClose (UInt16 portId)	
<b>Parameters</b>	-> portId	Port ID for port to be closed.
<b>Result</b>	This function returns the following error codes: errNone           No error. serErrBadPort    This port doesn't exist.	

## Serial Manager

### Serial Manager Functions

---

`serErrNotOpen` The serial port is not open.

`serErrNoDevicesAvail`  
No serial devices could be found.

**Comments** If a foreground port is being closed and a background port exists, the background will have access to the port as long as another foreground port is not opened.

If a foreground port is being closed and a yielded port exists, the yielded port will have access to the port as long as it does not yield to the opening of another foreground port. If there are both a yielded port and a background port for the foreground port being closed, the yielded port takes precedence over the background port.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmOpen](#), [SrmOpenBackground](#)

## SrmControl

**Purpose** Performs a serial control function.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmControl (UInt16 portId, UInt16 op, void *valueP, UInt16 *valueLenP)`

**Parameters**

<code>-&gt; portID</code>	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
<code>-&gt; op</code>	Control operation to perform. Specify one of the <a href="#">SrmCtlEnum</a> enumerated types.
<code>&lt;-&gt; valueP</code>	Pointer to a value to use for the operation. See Comments for details.
<code>&lt;-&gt; valueLenP</code>	Pointer to the size of <code>*valueP</code> . See Comments for details.

**Result** This function returns the following error codes:

<code>errNone</code>	No error.
<code>serErrBadParam</code>	An invalid op code was specified.
<code>serErrBadPort</code>	This port doesn't exist.
<code>serErrNotOpen</code>	The serial port is not open.
<code>serErrNoDevicesAvail</code>	No serial devices could be found.
<code>serErrNotSupported</code>	The specified op code is not supported in the current configuration.

**Comments** [Table 65.1](#) shows what to pass for the `valueP` and `valueLenP` parameters for each of the operation codes. Control codes not listed do not use these parameters. See [SrmCtlEnum](#) for a complete list of control codes.

**Table 65.1 SrmControl Parameters**

Operation Code	Parameters
<code>srmCtlSetBaudRate</code>	-> <code>valueP</code> = Pointer to <code>Int32</code> (baud rate) -> <code>valueLenP</code> = Pointer to <code>sizeof (Int32)</code>
<code>srmCtlGetBaudRate</code>	<- <code>valueP</code> = Pointer to <code>Int32</code> (baud rate) <- <code>valueLenP</code> = Pointer to <code>Int16</code>
<code>srmCtlSetFlags</code>	-> <code>valueP</code> = Pointer to <code>UInt32</code> (bitfield; see <a href="#">Serial Settings Constants</a> ) -> <code>valueLenP</code> = Pointer to <code>sizeof (UInt32)</code>
<code>srmCtlGetFlags</code>	<- <code>valueP</code> = Pointer to <code>UInt32</code> (bitfield) <- <code>valueLenP</code> = Pointer to <code>Int16</code>
<code>srmCtlSetCtsTimeout</code>	-> <code>valueP</code> = Pointer to <code>Int32</code> (timeout value) -> <code>valueLenP</code> = Pointer to <code>sizeof (Int32)</code>
<code>srmCtlGetCtsTimeout</code>	<- <code>valueP</code> = Pointer to <code>Int32</code> (timeout value) <- <code>valueLenP</code> = Pointer to <code>Int16</code>

## Serial Manager

### Serial Manager Functions

---

**Table 65.1 SrmControl Parameters (continued)**

Operation Code	Parameters
<code>srmCtlUserDef</code>	<-> <code>valueP</code> = Pointer passed to the serial or virtual driver <-> <code>valueLenP</code> = Pointer to <code>sizeof(Int32)</code> For a serial driver, these pointers are passed to the driver's control function and they contain that functions return values (if any) upon return.
<code>srmCtlGetOptimalTransmitSize</code>	<- <code>valueP</code> = Pointer to <code>Int32</code> <- <code>valueLenP</code> = Pointer to <code>sizeof(Int32)</code> If an error is returned by <code>SrmControl</code> , no buffering should be done. If <code>valueP</code> points to zero, buffering is requested, but the transmitting application cannot determine the buffer size. If <code>valueP</code> points to a number > 0, then try to send data in blocks of this number of bytes, as this is the most efficient block size for this particular device.
<code>srmCtlSetDTRAsserted</code>	-> <code>valueP</code> = Pointer to Boolean indicating whether to enable or disable DTR. -> <code>valueLenP</code> = Pointer to <code>sizeof(Boolean)</code>
<code>srmCtlGetDTRAsserted</code>	<- <code>valueP</code> = Pointer to Boolean indicating whether DTR is enabled. <- <code>valueLenP</code> = Pointer to <code>Int16</code>

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmCustomControl](#)

## SrmCustomControl

<b>Purpose</b>	Performs a custom serial control function.										
<b>Declared In</b>	SerialMgr.h										
<b>Prototype</b>	<pre>Err SrmCustomControl (UInt16 portId, UInt16 opCode, UInt32 creator, void *valueP, UInt16 *valueLenP)</pre>										
<b>Parameters</b>	<table><tr><td>-&gt; portID</td><td>Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a>.</td></tr><tr><td>-&gt; opCode</td><td>Control operation to perform. The op code must be greater than srmCtlCustom.</td></tr><tr><td>-&gt; creator</td><td>Creator ID of the driver that defines the op code. The combination of creator ID and op code uniquely identifies the operation to be performed.</td></tr><tr><td>&lt;-&gt; valueP</td><td>Pointer to a value to use for the operation.</td></tr><tr><td>&lt;-&gt; valueLenP</td><td>Pointer to the size of *valueP.</td></tr></table>	-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .	-> opCode	Control operation to perform. The op code must be greater than srmCtlCustom.	-> creator	Creator ID of the driver that defines the op code. The combination of creator ID and op code uniquely identifies the operation to be performed.	<-> valueP	Pointer to a value to use for the operation.	<-> valueLenP	Pointer to the size of *valueP.
-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .										
-> opCode	Control operation to perform. The op code must be greater than srmCtlCustom.										
-> creator	Creator ID of the driver that defines the op code. The combination of creator ID and op code uniquely identifies the operation to be performed.										
<-> valueP	Pointer to a value to use for the operation.										
<-> valueLenP	Pointer to the size of *valueP.										
<b>Result</b>	<p>This function returns the following error codes:</p> <table><tr><td>errNone</td><td>No error.</td></tr><tr><td>serErrNotSupported</td><td>The port is not the foreground port.</td></tr><tr><td>serErrBadPort</td><td>This port doesn't exist.</td></tr><tr><td>serErrNotOpen</td><td>The serial port is not open.</td></tr><tr><td>serErrNoDevicesAvail</td><td>No serial devices could be found.</td></tr></table>	errNone	No error.	serErrNotSupported	The port is not the foreground port.	serErrBadPort	This port doesn't exist.	serErrNotOpen	The serial port is not open.	serErrNoDevicesAvail	No serial devices could be found.
errNone	No error.										
serErrNotSupported	The port is not the foreground port.										
serErrBadPort	This port doesn't exist.										
serErrNotOpen	The serial port is not open.										
serErrNoDevicesAvail	No serial devices could be found.										
<b>Comments</b>	<p>This function is a mechanism for a virtual driver to create control codes specific to that driver, allowing for the support of new technologies that have interfaces through the Serial Manager.</p> <p>This function simply forwards the opCode and any valueP parameter to the virtual driver for the port. The virtual driver may</p>										

## Serial Manager

### Serial Manager Functions

---

return its own error code if the `opCode` or the input in `valueP` is invalid.

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present.

**See Also** [SrmControl](#)

## SrmExtOpen

**Purpose** Opens a foreground port connection with the specified configuration.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmExtOpen (UInt32 port, SrmOpenConfigType *configP, UInt16 configSize, UInt16 *newPortIdP)`

**Parameters**

-> <code>port</code>	The four-character port name (such as 'ircm' or 'u328') or logical port number to be opened. (See <a href="#">Port Constants</a> .)
-> <code>configP</code>	Pointer to the configuration structure specifying the serial port's properties. See <a href="#">SrmOpenConfigType</a> .
-> <code>configSize</code>	The size of the configuration structure pointed to by <code>configP</code> .
<- <code>newPortIdP</code>	Contains the port ID to be passed to other Serial Manager functions.

**Result** This function returns the following error codes:

<code>errNone</code>	No error.
<code>serErrBadPort</code>	The port parameter does not specify a valid port.
<code>serErrBadParam</code>	The <code>configP</code> parameter is NULL.

`serErrAlreadyOpen`

The Serial Manager already has a port open.

`memErrNotEnoughSpace`

There was not enough memory available to open the port.

**Comments** Do not keep the port open any longer than necessary. An open serial port consumes more energy from the device's batteries.

The values specified in the `configP` parameter depend on the type of connection being made. For RS-232 connections, you specify the baud rate but not a purpose. For USB connections, you specify a purpose but not a baud rate.

A newly opened port has its line errors cleared, the default CTS timeout set (specified by the constant `srnDefaultCTSTimeout`), a 512-byte receive queue allocated, 1 stop bit, 8 bits per character, RTS enabled, and flow control enabled. To increase the receive queue size, use [SrmSetReceiveBuffer](#). To change the other serial port settings, use [SrmControl](#).

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present. The `SrmExtOpen` function replaces the [SrmOpen](#) function.

**See Also** [SrmOpen](#), [SrmExtOpenBackground](#)

### SrmExtOpenBackground

**Purpose** Opens a port with the specified configuration in the background. Background ports relinquish control when another task opens the port with the [SrmOpen](#) or [SrmExtOpen](#) call.

**Declared In** SerialMgr.h

**Prototype** Err SrmExtOpenBackground (UInt32 port, SrmOpenConfigType \*configP, UInt16 configSize, UInt16 \*newPortIdP)

**Parameters**

-> port	Physical or logical port number to be opened. See <a href="#">Port Constants</a> for more information.
-> configP	Pointer to the configuration structure specifying the serial port's properties. See <a href="#">SrmOpenConfigType</a> .
-> configSize	The size of the configuration structure pointed to by configP.
<- newPortIdP	Contains the port ID to be passed to other Serial Manager functions.

**Result** This function returns the following error codes:

errNone	No error.
serErrAlreadyOpen	This port already has an installed background owner.
serErrBadPort	This port doesn't exist.
serErrNotSupported	This type of port cannot be opened in the background.
serErrBadParam	The configP parameter is NULL.
memErrNotEnoughSpace	There was not enough memory available to open the port.

**Comments** This function is provided to support tasks that want to use a serial device to receive data only when no other task is using the port.

If a background port is forced to surrender control of the hardware as a result of another task opening a foreground connection, all buffers for the background port are flushed. After this active task closes the port, active control of the port is returned to the background task. Only one task can have background ownership of the port.

Note that background ports have limited functionality: they can only receive data and notify owning clients of what data has been received.

The values specified in the `configP` parameter depend on the type of connection being made. For RS-232 connections, you specify the baud rate but not a purpose. For USB connections, you specify a purpose but not a baud rate.

**Compatibility** Implemented only if both [New Serial Manager Feature Set Version 2](#) and [4.0 New Feature Set](#) are present. The `SrmExtOpenBackground` function replaces the [SrmOpenBackground](#) function.

**See Also** [SrmOpen](#), [SrmExtOpen](#)

## SrmGetDeviceCount

**Purpose** Returns the number of available serial devices.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmGetDeviceCount (UInt16 *numOfDevicesP)`

**Parameters** `<- numOfDevicesP`  
Pointer to address where the number of serial devices is returned.

**Result** `errNone` No error.

## Serial Manager

### Serial Manager Functions

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmGetDeviceInfo](#)

## SrmGetDeviceInfo

**Purpose** Returns information about a serial device.

**Declared In** SerialMgr.h

**Prototype** Err SrmGetDeviceInfo (UInt32 deviceID,  
DeviceInfoType \*deviceInfoP)

**Parameters**

-> deviceID	ID of serial device to get information for. You can pass a zero-based index (0, 1, 2, ...), a valid port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> , or a 4-character port name (such as 'u328', 'u650', or 'ircm'). See <a href="#">Port Constants</a> .
<- deviceInfoP	Pointer to a <a href="#">DeviceInfoType</a> structure where information about the device is returned.

**Result** This function returns the following error codes:

errNone	No error.
serErrBadPort	This port doesn't exist.
serErrNoDevicesAvail	The Serial Manager cannot find any serial devices.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmGetDeviceCount](#)

## SrmGetStatus

<b>Purpose</b>	Returns status information about the serial hardware.								
<b>Declared In</b>	SerialMgr.h								
<b>Prototype</b>	<pre>Err SrmGetStatus (UInt16 portId,                  UInt32 *statusFieldP, UInt16 *lineErrsP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; portID</td><td>Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a>.</td></tr><tr><td>&lt;- statusFieldP</td><td>Pointer to address where hardware status information for the port is returned. This is a 32-bit field using the flags described in <a href="#">Status Constants</a>.</td></tr><tr><td>&lt;- lineErrsP</td><td>Pointer to address where the number of line errors for the port is returned. The line error flags are described in <a href="#">Line Error Constants</a>.</td></tr></table>	-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .	<- statusFieldP	Pointer to address where hardware status information for the port is returned. This is a 32-bit field using the flags described in <a href="#">Status Constants</a> .	<- lineErrsP	Pointer to address where the number of line errors for the port is returned. The line error flags are described in <a href="#">Line Error Constants</a> .		
-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .								
<- statusFieldP	Pointer to address where hardware status information for the port is returned. This is a 32-bit field using the flags described in <a href="#">Status Constants</a> .								
<- lineErrsP	Pointer to address where the number of line errors for the port is returned. The line error flags are described in <a href="#">Line Error Constants</a> .								
<b>Result</b>	<p>This function returns the following error codes:</p> <table><tr><td>errNone</td><td>No error.</td></tr><tr><td>serErrBadPort</td><td>This port doesn't exist.</td></tr><tr><td>serErrNotSupported</td><td>The port is a yielded port.</td></tr><tr><td>serErrNoDevicesAvail</td><td>No serial devices could be found.</td></tr></table>	errNone	No error.	serErrBadPort	This port doesn't exist.	serErrNotSupported	The port is a yielded port.	serErrNoDevicesAvail	No serial devices could be found.
errNone	No error.								
serErrBadPort	This port doesn't exist.								
serErrNotSupported	The port is a yielded port.								
serErrNoDevicesAvail	No serial devices could be found.								
<b>Comments</b>	Typically, SrmGetStatus is called to retrieve the line errors for the port if some of the send and receive functions return a serErrLineErr error code.								
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.								

## Serial Manager

### Serial Manager Functions

---

## SrmOpen

<b>Purpose</b>	Opens a foreground port connection with the specified port name or logical port number.								
<b>Declared In</b>	SerialMgr.h								
<b>Prototype</b>	Err SrmOpen (UInt32 port, UInt32 baud, UInt16 *newPortIdP)								
<b>Parameters</b>	<table><tr><td>-&gt; port</td><td>The four-character port name or logical port number to be opened. See <a href="#">Port Constants</a> for more information.</td></tr><tr><td>-&gt; baud</td><td>Initial baud rate of port.</td></tr><tr><td>&lt;- newPortIdP</td><td>Contains the port ID to be passed to other Serial Manager functions.</td></tr></table>	-> port	The four-character port name or logical port number to be opened. See <a href="#">Port Constants</a> for more information.	-> baud	Initial baud rate of port.	<- newPortIdP	Contains the port ID to be passed to other Serial Manager functions.		
-> port	The four-character port name or logical port number to be opened. See <a href="#">Port Constants</a> for more information.								
-> baud	Initial baud rate of port.								
<- newPortIdP	Contains the port ID to be passed to other Serial Manager functions.								
<b>Result</b>	This function returns the following error codes: <table><tr><td>errNone</td><td>No error.</td></tr><tr><td>serErrAlreadyOpen</td><td>This port already has an installed foreground owner.</td></tr><tr><td>serErrBadPort</td><td>This port doesn't exist.</td></tr><tr><td>memErrNotEnoughSpace</td><td>There was not enough memory available to open the port.</td></tr></table>	errNone	No error.	serErrAlreadyOpen	This port already has an installed foreground owner.	serErrBadPort	This port doesn't exist.	memErrNotEnoughSpace	There was not enough memory available to open the port.
errNone	No error.								
serErrAlreadyOpen	This port already has an installed foreground owner.								
serErrBadPort	This port doesn't exist.								
memErrNotEnoughSpace	There was not enough memory available to open the port.								
<b>Comments</b>	Only one application or task may have access to a particular serial port at any time.  Do not keep the port open any longer than necessary. An open serial port consumes more energy from the device's batteries.								
<b>Compatibility</b>	Implemented only if <a href="#">New Serial Manager Feature Set Version 1</a> is present.								

If [New Serial Manager Feature Set Version 2](#) is present, the `SrmOpen` function is replaced by [SrmExtOpen](#). `SrmOpen` is supported for backward compatibility.

**See Also** [SrmOpenBackground](#)

## SrmOpenBackground

**Purpose** Allows a task to open, initialize, and use the port, but always relinquishes control of the port when another task opens the port with the [SrmOpen](#) call.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmOpenBackground (UInt32 port, UInt32 baud, UInt16 *newPortIdP)`

**Parameters**

-> port	The four-character port name or logical port number to be opened. See <a href="#">Port Constants</a> for more information.
-> baud	Initial baud rate of port.
<- newPortIdP	Contains the port ID to be passed to other Serial Manager functions.

**Result** This function returns the following error codes:

<code>errNone</code>	No error.
<code>serErrAlreadyOpen</code>	This port already has an installed background owner.
<code>serErrBadPort</code>	This port doesn't exist.
<code>memErrNotEnoughSpace</code>	There was not enough memory available to open the port.

**Comments** This function is provided to support tasks that want to use a serial device to receive data only when no other task is using the port.

## Serial Manager

### Serial Manager Functions

---

If a background port is forced to surrender control of the hardware as a result of another task opening a foreground connection, all buffers for the background port are flushed. After this active task closes the port, active control of the port is returned to the background task. Only one task can have background ownership of the port.

Note that background ports have limited functionality: they can only receive data and notify owning clients of what data has been received.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

If [New Serial Manager Feature Set Version 2](#) is present, the `SrmOpenBackground` function is replaced by [SrmExtOpenBackground](#). `SrmOpenBackground` is supported for backward compatibility.

**See Also** [SrmOpen](#)

## SrmPrimeWakeupHandler

**Purpose** Sets the number of received bytes that triggers a call to the wakeup handler function.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmPrimeWakeupHandler (UInt16 portId, UInt16 minBytes)`

**Parameters**

<code>-&gt; portId</code>	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
<code>-&gt; minBytes</code>	Number of bytes that must be received before wakeup handler is called. Typically, this is set to 1.

**Result** This function returns the following error codes:

<code>errNone</code>	No error.
----------------------	-----------

serErrBadPort    This port doesn't exist.  
serErrNotOpen    The port is not open.  
serErrNoDevicesAvail  
                  No serial devices could be found.

**Comments**    This function primes a wakeup handler installed by [SrmSetWakeupHandler](#).

**Compatibility**    Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also**    [SrmSetWakeupHandler](#), [WakeupHandlerProcPtr](#)

## SrmReceive

**Purpose**    Receives a specified number of bytes.

**Declared In**    SerialMgr.h

**Prototype**    `UInt32 SrmReceive (UInt16 portId, void *rcvBufP, UInt32 count, Int32 timeout, Err *errP)`

**Parameters**

-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
<- rcvBufP	Pointer to buffer where received data is to be returned.
-> count	Length of data buffer (in bytes). This specifies the number of bytes to receive.
-> timeout	The amount of time (in ticks) that the Serial Manager waits to receive the requested block of data. At the end of the timeout, data received up to that time is returned.
<- errP	Error code.

**Result**    Number of bytes of data actually received.

## Serial Manager

### Serial Manager Functions

---

<b>Comments</b>	The following error codes can be returned in <code>errP</code> :
<code>errNone</code>	No error.
<code>serErrBadPort</code>	This port doesn't exist.
<code>serErrNotOpen</code>	The port is not open.
<code>serErrTimeout</code>	Unable to receive data within the specified timeout period.
<code>serErrConfigurationFailed</code>	The port needs time to configure, and the configuration has failed.
<code>serErrNotSupported</code>	The port is not the foreground port.
<code>serErrConfigurationFailed</code>	The port could not configure itself.
<code>serErrLineErr</code>	A line error occurred during the receipt of data. Use <a href="#">SrmGetStatus</a> to obtain the exact line error.
<code>serErrNoDevicesAvail</code>	No serial devices could be found.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmReceiveCheck](#), [SrmReceiveFlush](#), [SrmReceiveWait](#)

## SrmReceiveCheck

- Purpose** Checks the receive FIFO and returns the number of bytes in the serial receive queue.
- Declared In** SerialMgr.h
- Prototype** Err SrmReceiveCheck (UInt16 portId, UInt32 \*numBytesP)
- Parameters**
- |              |   |
|--------------|---|
| -> portID    | Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> . |
| <- numBytesP | Number of bytes in the receive queue.   |
- Result** This function returns the following error codes:
- |               |   |
|---------------|---|
| errNone       | No error.   |
| serErrBadPort | This port doesn't exist.  |
| serErrNotOpen | The port is not open.   |
| serErrLineErr | A line error has occurred. Use <a href="#">SrmGetStatus</a> to obtain the exact line error. |
- Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.
- See Also** [SrmReceive](#), [SrmReceiveFlush](#), [SrmReceiveWait](#)

## SrmReceiveFlush

- Purpose** Flushes the receive FIFOs.
- Declared In** SerialMgr.h
- Prototype** Err SrmReceiveFlush (UInt16 portId, Int32 timeout)
- Parameters**
- |           |   |
|-----------|---|
| -> portId | Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> . |
|-----------|---|

## Serial Manager

### Serial Manager Functions

---

-> timeout            Timeout value, in ticks.

**Result**    This function returns the following error codes:

errNone            No error.

serErrBadPort    This port doesn't exist.

serErrNotOpen    The port is not open.

serErrNotSupported  
                    The port is not the foreground port.

serErrNoDevicesAvail  
                    No serial devices could be found.

**Comments**    The `timeout` value forces this function to wait a period of ticks after flushing the port to see if more data shows up to be flushed. If more data arrives within the timeout period, the port is flushed again and the timeout counter is reset and waits again. The function only exits after no more bytes are received by the port for the full timeout period since the last flush of the port. To avoid this waiting behavior, specify 0 for the timeout period.

Any errors on the line are cleared before this function returns.

**Compatibility**    Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also**        [SrmReceive](#), [SrmReceiveCheck](#), [SrmReceiveWait](#)

## SrmReceiveWait

- Purpose**      Waits until some number of bytes of data have arrived into the serial receive queue, then returns.
- Declared In**    SerialMgr.h
- Prototype**    Err SrmReceiveWait (UInt16 portId, UInt32 bytes, Int32 timeout)
- Parameters**
- > portID            Port ID returned from [SrmOpen](#) or [SrmExtOpen](#).
  - > bytes             Number of bytes to wait for.
  - > timeout            Timeout value, in ticks.
- Result**      This function returns the following error codes:
- errNone             No error.
  - serErrBadPort      This port doesn't exist.
  - serErrNotOpen      The port is not open.
  - serErrTimeOut      Unable to receive data within the specified timeout period.
  - serErrNotSupported      The port is not the foreground port.
  - serErrBadParam     The bytes parameter exceeds the size of the receive queue. Use [SrmSetReceiveBuffer](#) to increase the size of the receive queue.
  - serErrLineErr      A line error occurred during the receipt of data. Use [SrmGetStatus](#) to obtain the exact line error.
  - serErrNoDevicesAvail      No serial devices could be found.
- Comments**    If this function returns no error, the application can either check the number of bytes currently in the receive queue (using

## Serial Manager

### Serial Manager Functions

---

[SrmReceiveCheck](#)) or it can just specify a buffer and receive the data by calling [SrmReceive](#).

Do not call `SerReceiveWait` from within a wakeup handler. If you do, the `serErrTimeOut` error is returned.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmReceive](#), [SrmReceiveCheck](#), [SrmReceiveFlush](#)

## SrmReceiveWindowClose

**Purpose** Closes direct access to the Serial Manager's receive queue.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmReceiveWindowClose (UInt16 portId, UInt32 bytesPulled)`

**Parameters**

-> portId	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
-> bytesPulled	Number of bytes the application read from the receive queue.

**Result** This function returns the following error codes:

<code>errNone</code>	No error.
<code>serErrBadPort</code>	This port doesn't exist.
<code>serErrNotOpen</code>	The port is not open.
<code>serErrNotSupported</code>	The port is not the foreground port.
<code>serErrNoDevicesAvail</code>	No serial devices could be found.

**Comments** Call this function when the application has read as many bytes as it needs out of the receive queue or it has read all the available bytes.

## Serial Manager

### Serial Manager Functions

---

Applications that want to empty the receive buffer entirely should call the `SrmReceiveWindowOpen` and `SrmReceiveWindowClose` functions repeatedly until the buffer size returned is 0.

---

**IMPORTANT:** Once an application calls `SrmReceiveWindowOpen`, it should not attempt to receive data via the normal method of calling [SrmReceive](#) or [SrmReceiveWait](#), as these functions interfere with direct access to the receive queue.

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmReceiveWindowClose](#)

## SrmSend

**Purpose** Sends a block of data out the specified port.

**Declared In** `SerialMgr.h`

**Prototype** `UInt32 SrmSend (UInt16 portId, const void *bufP, UInt32 count, Err *errP)`

**Parameters**

-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
-> bufp	Pointer to data to send.
-> count	Length of data buffer, in bytes.
<- errP	Error code. See the Comments section for details.

**Result** Number of bytes of data actually sent.

**Comments** When `SrmSend` returns, you should check the value returned in the `errP` parameter. If `errNone`, then the entire data buffer was sent. If

not `errNone`, then the result equals the number of bytes sent before the error occurred. The possible error values are:

<code>errNone</code>	No error.
<code>serErrBadPort</code>	This port doesn't exist.
<code>serErrNotOpen</code>	The port is not open.
<code>serErrTimeout</code>	Unable to send data within the specified CTS timeout period.
<code>serErrNoDevicesAvail</code>	No serial devices could be found.
<code>serErrConfigurationFailed</code>	The port configuration has failed.
<code>serErrNotSupported</code>	The specified port is not the foreground port.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSendCheck](#), [SrmSendFlush](#), [SrmSendWait](#)

## SrmSendCheck

**Purpose** Checks the transmit FIFO and returns the number of bytes left to be sent.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmSendCheck (UInt16 portId, UInt32 *numBytesP)`

**Parameters**

<code>-&gt; portID</code>	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
<code>&lt;- numBytesP</code>	Number of bytes left in the FIFO queue.

**Result** This function returns the following error codes:

<code>errNone</code>	No error.
----------------------	-----------

## Serial Manager

### Serial Manager Functions

---

`serErrBadPort` This port doesn't exist.  
`serErrNotOpen` The port is not open.  
`serErrNotSupported`  
This feature not supported by the hardware.  
`serErrNoDevicesAvail`  
No serial devices could be found.

**Comments** Not all serial devices support this feature.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSend](#), [SrmSendFlush](#), [SrmSendWait](#)

## SrmSendFlush

**Purpose** Flushes the transmit FIFO.

**Declared In** `SerialMgr.h`

**Prototype** `Err SrmSendFlush (UInt16 portId)`

**Parameters** `-> portID` Port ID returned from [SrmOpen](#) or [SrmExtOpen](#).

**Result** This function returns the following error codes:

`errNone` No error.  
`serErrBadPort` This port doesn't exist.  
`serErrNotOpen` The port is not open.  
`serErrNotSupported`  
The port is not the foreground port.  
`serErrNoDevicesAvail`  
No serial devices could be found.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSend](#), [SrmSendCheck](#), [SrmSendWait](#)

## SrmSendWait

**Purpose** Waits until all previous data has been sent from the transmit FIFO, then returns.

**Declared In** SerialMgr.h

**Prototype** Err SrmSendWait (UInt16 portId)

**Parameters** -> portID Port ID returned from [SrmOpen](#) or [SrmExtOpen](#).

**Result** This function returns the following error codes:

errNone	No error.
serErrBadPort	This port doesn't exist.
serErrNotOpen	The port is not open.
serErrTimeout	Unable to send data within the CTS timeout period.
serErrNotSupported	The port is not the foreground port.
serErrNoDevicesAvail	No serial devices could be found.

**Comments** Consider calling this function if your software needs to detect when all data has been transmitted by [SrmSend](#). The [SrmSend](#) function blocks until all data has been transmitted or a timeout occurs. A subsequent call to [SrmSendWait](#) blocks until all data queued up for transmission has been transmitted or until another CTS timeout occurs (if CTS handshaking is enabled).

## Serial Manager

### Serial Manager Functions

---

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmSend](#), [SrmSendCheck](#), [SrmSendFlush](#)

## SrmSetReceiveBuffer

**Purpose** Installs a new buffer into the Serial Manager's receive queue.

**Declared In** SerialMgr.h

**Prototype** Err SrmSetReceiveBuffer (UInt16 portId,  
void \*bufP, UInt16 bufSize)

**Parameters**

-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
-> bufP	Pointer to new receive buffer. Ignored if bufSize is NULL.
-> bufSize	Size of new receive buffer in bytes. To remove this buffer and allocate a new default buffer (512 bytes), specify NULL.

**Result** This function returns the following error codes:

errNone	No error.
serErrBadPort	This port doesn't exist.
serErrNotOpen	This port is not open.
memErrNotEnoughSpace	Not enough memory to allocate default buffer.
serErrNoDevicesAvail	No serial devices could be found.

**Comments** The buffer that you pass to this function must remain allocated while you have the serial port open. Before you close the serial port, you must restore the default queue by calling `SrmSetReceiveBuffer` with NULL as the `bufP` and `bufSize` arguments.

---

**IMPORTANT:** Applications must install the default buffer before closing the port (or disposing of the new receive queue).

---

**Compatibility**    Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

## SrmSetWakeupHandler

**Purpose**            Installs a wakeup handler.

**Declared In**      SerialMgr.h

**Prototype**        Err SrmSetWakeupHandler (UInt16 portId,  
                          WakeupHandlerProcPtr procP, UInt32 refCon)

**Parameters**

-> portID	Port ID returned from <a href="#">SrmOpen</a> or <a href="#">SrmExtOpen</a> .
-> procP	Pointer to a <a href="#">WakeupHandlerProcPtr</a> function. Specify NULL to remove a handler.
-> refCon	User-defined data that is passed to the wakeup handler function. This can be a pointer or not.

**Result**            This function returns the following error codes:

errNone	No error.
serErrBadPort	This port doesn't exist.
serErrNotOpen	The port is not open.
serErrNoDevicesAvail	No serial devices could be found.

**Comments**        The wakeup handler is a function in your application that you want to be called whenever there is data ready to be received on the specified port.

The wakeup handler function will not become active until it is primed with a number of bytes that is greater than 0, by the

## Serial Manager

### Serial Manager Application-Defined Functions

---

[SrmPrimeWakeupHandler](#) function. Every time a wakeup handler is called, it must be re-primed (using [SrmPrimeWakeupHandler](#)) in order to be called again.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmPrimeWakeupHandler](#), [WakeupHandlerProcPtr](#)

## Serial Manager Application-Defined Functions

### WakeupHandlerProcPtr

**Purpose** Called after some number of bytes are received by the Serial Manager's interrupt function.

**Declared In** SerialMgr.h

**Prototype** void (\*WakeupHandlerProcPtr)(UInt32 refCon)

**Parameters** ->refCon User-defined data passed from the [SrmSetWakeupHandler](#) function.

**Result** Returns nothing.

**Comments** This handler function is installed by calling [SrmSetWakeupHandler](#). The number of bytes after which it is called is specified by [SrmPrimeWakeupHandler](#).

---

**IMPORTANT:** Because wakeup handlers are called during interrupt time, they cannot call **any** Palm OS® system functions, including [SrmReceive](#), that may block the system in any way. Wakeup handlers should also be very short so as to reduce interrupt latency.

---

Two common implementations of wakeup handlers include:

- Calling [EvtWakeup](#), which causes any pending `EvtGetEvent` call to return and then sends a `nilEvent` to the current application.
- Using [SrmReceiveWindowOpen](#) and [SrmReceiveWindowClose](#) to gain direct access to the receive queue without blocking.

**Compatibility** Implemented only if [New Serial Manager Feature Set Version 1](#) is present.

**See Also** [SrmPrimeWakeupHandler](#), [SrmSetWakeupHandler](#)

## **Serial Manager**

### *Serial Manager Application-Defined Functions*

---

# Old Serial Manager

---

This chapter provides reference material for the serial manager API:

- [Serial Manager Data Structures](#)
- [Serial Manager Functions](#)

The header file `SerialMgrOld.h` declares the serial manager API. For more information on the serial manager, see the chapter “[Serial Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

---

**NOTE:** The API described in this chapter is obsolete if the [New Serial Manager Feature Set](#) is present. The API is still supported for backward compatibility; however, the Serial Manager APIs are preferred.

---

## Serial Manager Data Structures

### SerCtlEnum

To perform a control function, applications call [SerControl](#), which performs one of the control operations specified by `SerCtlEnum`, which has the following elements:

Element	Description
<code>serCtlFirstReserved = 0</code>	Reserve 0
<code>serCtlStartBreak</code>	Turn RS232 break signal on. Applications have to make sure that the break is set long enough to generate a value BREAK! valueP = 0; valueLenP = 0
<code>serCtlStopBreak</code>	Turn RS232 break signal off: valueP = 0; valueLenP = 0

## Old Serial Manager

### *Serial Manager Data Structures*

---

Element	Description
serCtlBreakStatus	Get RS232 break signal status (on or off): valueP = ptr to Word for returning status (0 = off, !0 = on)  *valueLenP = sizeof(Word)
serCtlStartLocalLoopback	Start local loopback test; valueP = 0, valueLenP = 0
serCtlStopLocalLoopback	Stop local loopback test valueP = 0, valueLenP = 0
serCtlMaxBaud	valueP = ptr to DWord for returned baud *valueLenP = sizeof(DWord)
serCtlHandshakeThreshold	Retrieve HW handshake threshold; this is the maximum baud rate that does not require hardware handshaking valueP = ptr to DWord for returned baud *valueLenP = sizeof(DWord)
serCtlEmuSetBlockingHook	Set a blocking hook routine. <hr/> <b>WARNING!</b> WARNING: For use with the Simulator on Mac OS only: NOT SUPPORTED ON THE PALM DEVICE. <hr/> valueP = ptr to SerCallbackEntryType *valueLenP=sizeof(SerCallbackEntryType) Returns the old settings in the first argument.
serCtlLAST	Add new address entries before this one.

## SerSettingsType

The SerSettingsType structure defines serial port attributes; it is used by the calls [SerGetSettings](#) and [SerSetSettings](#). The SerSettingsPtr type points to a SerSettingsType structure.

```
typedef struct SerSettingsType {  
    UInt32 baudRate;
```

```
    UInt32 flags;  
    Int32  ctsTimeout;  
} SerSettingsType;  
  
typedef SerSettingsType* SerSettingsPtr;
```

### **Field Descriptions**

baudRate	Baud rate
flags	Miscellaneous settings
ctsTimeout	Maximum number of ticks to wait for CTS to become asserted before transmitting; used only when configured with the <code>serSettingsFlagCTSAutoM</code> flag.

## **Serial Manager Functions**

### **SerClearErr**

<b>Purpose</b>	Reset the serial port's line error status.
<b>Declared In</b>	<code>SerialMgrOld.h</code>
<b>Prototype</b>	<code>Err SerClearErr (UInt16 refNum)</code>
<b>Parameters</b>	-> refNum            The serial library reference number.
<b>Result</b>	0                    No error.
<b>Comments</b>	Call <code>SerClearErr</code> only after a serial manager function ( <code>SerReceive</code> , <code>SerReceiveCheck</code> , <code>SerSend</code> , etc.) returns with the error code <code>serErrLineErr</code> .  The reason for this is that <code>SerClearErr</code> resets the serial port. So, if <code>SerClearErr</code> is called unconditionally while a byte is coming into the serial port, that byte is guaranteed to become corrupted.

## Old Serial Manager

### Serial Manager Functions

---

The right strategy is to always check the error code returned by a serial manager function. If it's `serErrLineErr`, call `SerClearErr` immediately. However, don't make unsolicited calls to `SerClearErr`.

When you get `serErrLineErr`, consider flushing the receive queue for a fraction of a second by calling `SerReceiveFlush`. `SerReceiveFlush` calls `SerClearErr` for you.

## SerClose

<b>Purpose</b>	Release the serial port previously acquired by <code>SerOpen</code> .
<b>Declared In</b>	<code>SerialMgrOld.h</code>
<b>Prototype</b>	<code>Err SerClose (UInt16 refNum)</code>
<b>Parameters</b>	<code>-&gt; refNum</code> Serial library reference number.
<b>Result</b>	<code>0</code> No error. <code>serErrNotOpen</code> Port wasn't open. <code>serErrStillOpen</code> Port still held open by another process.
<b>Comments</b>	Releases the serial port and shuts down serial port hardware if the open count has reached 0. Open serial ports consume more energy from the device's batteries; it's therefore essential to keep a port open only as long as necessary.
<b>Caveat</b>	Don't call <code>SerClose</code> unless the return value from <a href="#">SerOpen</a> was 0 (zero) or <code>serErrAlreadyOpen</code> .
<b>See Also</b>	<a href="#">SerOpen</a>

## SerControl

<b>Purpose</b>	Perform a control function.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerControl (UInt16 refNum, UInt16 op, void *valueP, UInt16 *valueLenP)
<b>Parameters</b>	-> refNum           Reference number of library. -> op                Control operation to perform (SerCtlEnum). <-> valueP         Pointer to value for operation. <-> valueLenP      Pointer to size of value.
<b>Result</b>	0                    No error. serErrBadParam    Invalid parameter (unknown). serErrNotOpen     Library not open.
<b>Comments</b>	This function provides extensible control features for the serial manager. You can <ul style="list-style-type: none"><li>• Turn on/off the RS232 break signal and check its status.</li><li>• Perform a local loopback test.</li><li>• Get the maximum supported baud rate.</li><li>• Get the hardware handshake threshold baud rate.</li></ul>
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.

## SerGetSettings

- Purpose** Fill in the [SerSettingsType](#) structure with current serial port attributes.
- Declared In** SerialMgrOld.h
- Prototype** `Err SerGetSettings (UInt16 refNum, SerSettingsPtr settingsP)`
- Parameters**
- |               |   |
|---------------|---|
| -> refNum     | Serial library reference number.                                      |
| <-> settingsP | Pointer to <a href="#">SerSettingsType</a> structure to be filled in. |
- Result**
- |               |                       |
|---------------|-----------------------|
| 0             | No error.             |
| serErrNotOpen | The port wasn't open. |
- Comments** The information returned by this call includes the current baud rate, CTS timeout, handshaking options, and data format options. See the [SerSettingsType](#) structure for more details.
- See Also** [SerSend](#)

## SerGetStatus

- Purpose** Return the pending line error status for errors that have been detected since the last time [SerClearErr](#) was called.
- Declared In** SerialMgrOld.h
- Prototype** `UInt16 SerGetStatus (UInt16 refNum, Boolean *ctsOnP, Boolean *dsrOnP)`
- Parameters**
- |           |  |
|-----------|--|
| -> refNum | Serial library reference number.                 |
| -> ctsOnP | Pointer to location for storing a Boolean value. |

-> dsrOnP            Pointer to location for storing a Boolean value.

**Result**            Returns any combination of the following constants, bitwise OR'ed together:

serLineErrorParity  
                        Parity error.

serLineErrorHWOvrerrun  
                        Hardware overrun.

serLineErrorFraming  
                        Framing error.

serLineErrorBreak  
                        Break signal detected.

serLineErrorHShake  
                        Line handshake error.

serLineErrorSWOvrerrun  
                        Software overrun.

**Comments**            When another serial manager function returns an error code of serErrLineErr, SerGetStatus can be used to find out the specific nature of the line error(s).

The values returned via ctsOnP and dsrOnP are not meaningful in the present version of the software

**See Also**            [SerClearErr](#)

## **SerOpen**

**Purpose**              Acquire and open a serial port with given baud rate and default settings.

**Declared In**        SerialMgrOld.h

**Prototype**         Err SerOpen (UInt16 refNum, UInt16 port, UInt32 baud)

**Parameters**        -> refNum            Serial library reference number.

## Old Serial Manager

### Serial Manager Functions

---

-> port            Port number.

-> baud            Baud rate.

**Result**    0            No error.

`serErrAlreadyOpen`

Port was open. Enables port sharing by  
“friendly” clients (not recommended).

`serErrBadParam` Invalid parameter.

`memErrNotEnoughSpace`

Insufficient memory.

#### Comments

Acquires the serial port, powers it up, and prepares it for operation. To obtain the serial library reference number, call [SysLibFind](#) with “Serial Library” as the library name. This reference number must be passed as a parameter to all serial manager functions. The device currently contains only one serial port with port number 0 (zero).

The baud rate is an integral baud value (for example - 300, 1200, 2400, 9600, 19200, 38400, 57600, etc.). The Palm OS® device has been tested at the standard baud rates in the range of 300 - 57600 baud. Baud rates through 1 Mbit are theoretically possible. Use CTS handshaking at baud rates above 19200 (see [SerSetSettings](#)).

An error code of 0 (zero) or `serErrAlreadyOpen` indicates that the port was successfully opened. If the port is already open when `SerOpen` is called, the port’s open count is incremented and an error code of `serErrAlreadyOpen` is returned. This ability to open the serial port multiple times allows cooperating tasks to share the serial port. Other tasks must refrain from using the port if `serErrAlreadyOpen` is returned and close it by calling [SerClose](#).

## SerReceive

**Purpose**      Receives `size` bytes worth of data or returns with error if a line error or timeout is encountered.

**Declared In**    `SerialMgrOld.h`

**Prototype**    `UInt32 SerReceive (UInt16 refNum, void *bufP, UInt32 count, Int32 timeout, Err* errP)`

**Parameters**

<code>refNum</code>	Serial library reference number.
<code>&lt;-&gt; bufP</code>	Buffer for receiving data.
<code>-&gt; count</code>	Number of bytes to receive.
<code>-&gt; timeout</code>	Interbyte timeout in ticks, 0 for none, -1 forever.
<code>&lt;-&gt; errP</code>	For returning error code.

**Result**      Number of bytes received:

<code>*errP = 0</code>	No error.
<code>serErrLineErr</code>	RS232 line error.
<code>serErrTimeOut</code>	Interbyte timeout.

**Compatibility**    Implemented only if [2.0 New Feature Set](#) is present.

---

**NOTE:**    The old versions of `SerSend` and `SerReceive` are still available as `SerSend10` and `SerReceive10` (not V10).

---

**See Also**      [SerReceive10](#)

## SerReceive10

<b>Purpose</b>	Receive a stream of bytes.								
<b>Declared In</b>	SerialMgrOld.h								
<b>Prototype</b>	Err SerReceive10 (UInt16 refNum, void *bufP, UInt32 bytes, Int32 timeout)								
<b>Parameters</b>	<table><tr><td>-&gt; refNum</td><td>The serial library reference number.</td></tr><tr><td>-&gt; bufP</td><td>Pointer to the buffer for receiving data.</td></tr><tr><td>-&gt; bytes</td><td>Number of bytes desired.</td></tr><tr><td>-&gt; timeout</td><td>Interbyte time out in system ticks (-1 = forever).</td></tr></table>	-> refNum	The serial library reference number.	-> bufP	Pointer to the buffer for receiving data.	-> bytes	Number of bytes desired.	-> timeout	Interbyte time out in system ticks (-1 = forever).
-> refNum	The serial library reference number.								
-> bufP	Pointer to the buffer for receiving data.								
-> bytes	Number of bytes desired.								
-> timeout	Interbyte time out in system ticks (-1 = forever).								
<b>Result</b>	<table><tr><td>0</td><td>No error. Requested number of bytes was received.</td></tr><tr><td>serErrTimeOut</td><td>Interbyte time out exceeded while waiting for the next byte to arrive.</td></tr><tr><td>serErrLineErr</td><td>Line error occurred (see <a href="#">SerClearErr</a> and <a href="#">SerGetStatus</a>).</td></tr></table>	0	No error. Requested number of bytes was received.	serErrTimeOut	Interbyte time out exceeded while waiting for the next byte to arrive.	serErrLineErr	Line error occurred (see <a href="#">SerClearErr</a> and <a href="#">SerGetStatus</a> ).		
0	No error. Requested number of bytes was received.								
serErrTimeOut	Interbyte time out exceeded while waiting for the next byte to arrive.								
serErrLineErr	Line error occurred (see <a href="#">SerClearErr</a> and <a href="#">SerGetStatus</a> ).								
<b>Comments</b>	<p>SerReceive blocks until all the requested data has been received or an error occurs. Because this call returns immediately without any data if line errors are pending, it is important to acknowledge the detection of line errors by calling <a href="#">SerClearErr</a>. If you just need to retrieve all or some of the bytes which are already in the receive queue, call <a href="#">SerReceiveCheck</a> first to get the count of bytes presently in the receive queue.</p>								
<b>Compatibility</b>	This function corresponds to the 1.0 version of SerReceive.								

## SerReceiveCheck

<b>Purpose</b>	Return the count of bytes presently in the receive queue.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerReceiveCheck (UInt16 refNum, UInt32 *numBytesP)
<b>Parameters</b>	-> refNum            Serial library reference number. <-> numBytesP      Pointer to location for returning the byte count.
<b>Result</b>	0                    No error. serErrLineErr      Line error pending (see <a href="#">SerClearErr</a> and <a href="#">SerGetStatus</a> ).
<b>Comments</b>	Because this call does not return the byte count if line errors are pending, it is important to acknowledge the detection of line errors by calling <a href="#">SerClearErr</a> .
<b>See Also</b>	<a href="#">SerReceiveWait</a>

## SerReceiveFlush

<b>Purpose</b>	Discard all data presently in the receive queue and flush bytes coming into the serial port. Clear the saved error status.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	void SerReceiveFlush (UInt16 refNum, Int32 timeout)
<b>Parameters</b>	-> refNum            Serial library reference number. -> timeout           Interbyte time out in system ticks (-1 = forever).
<b>Result</b>	Returns nothing.

## Old Serial Manager

### Serial Manager Functions

---

**Comments** `SerReceiveFlush` blocks until a timeout occurs while waiting for the next byte to arrive.

## SerReceiveWait

**Purpose** Wait for at least `bytes` bytes of data to accumulate in the receive queue.

**Declared In** `SerialMgrOld.h`

**Prototype** `Err SerReceiveWait (UInt16 refNum, UInt32 bytes, Int32 timeout)`

**Parameters**

- > `refNum` Serial library reference number.
- > `bytes` Number of bytes desired.
- > `timeout` Interbyte timeout in system ticks (-1 = forever).

**Result**

- 0 No error.
- `serErrTimeOut` Interbyte timeout exceeded while waiting for next byte to arrive.
- `serErrLineErr` Line error occurred (see [SerClearErr](#) and [SerGetStatus](#)).

**Comments** This is the preferred method of waiting for serial input, since it blocks the current task and allows switching the processor into a more energy-efficient state.

`SerReceiveWait` blocks until the desired number of bytes accumulate in the receive queue or an error occurs. The desired number of bytes must be less than the current receive queue size. The default queue size is 512 bytes. Because this call returns immediately if line errors are pending, it is important to acknowledge the detection of line errors by calling [SerClearErr](#).

**See Also** [SerReceiveCheck](#), [SerSetReceiveBuffer](#)

## SerSend

<b>Purpose</b>	Send one or more bytes of data over the serial port.								
<b>Declared In</b>	SerialMgrOld.h								
<b>Prototype</b>	<pre>UInt32 SerSend (UInt16 refNum, void *bufP,                 UInt32 count, Err *errP</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; refNum</td><td>Serial library reference number.</td></tr><tr><td>-&gt; bufP</td><td>Pointer to data to send.</td></tr><tr><td>-&gt; count</td><td>Number of bytes to send.</td></tr><tr><td>&lt;-&gt; errP</td><td>For returning error code.</td></tr></table>	-> refNum	Serial library reference number.	-> bufP	Pointer to data to send.	-> count	Number of bytes to send.	<-> errP	For returning error code.
-> refNum	Serial library reference number.								
-> bufP	Pointer to data to send.								
-> count	Number of bytes to send.								
<-> errP	For returning error code.								
<b>Result</b>	Returns the number of bytes transferred. Stores in errP: 0 No error. serErrTimeout Handshake timeout. The old calls worked, but they did not return enough info when they failed. The new calls (available in Palm OS v2.0 and greater) add more parameters to solve this problem and make serial communications programming simpler. Don't call the new functions when running on Palm OS 1.0.								
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.								
	<hr/> <b>NOTE:</b> The old versions of SerSend and SerReceive are still available as SerSend10 and SerReceive10 (not V10). <hr/>								
<b>See Also</b>	<a href="#">SerSend10</a> , <a href="#">SerSendWait</a>								

## SerSend10

<b>Purpose</b>	Send a stream of bytes to the serial port.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerSend10 (UInt16 refNum, void *bufP, UInt32 size)
<b>Parameters</b>	-> refNum            Serial library reference number. -> bufP             Pointer to the data to send. -> size              Size (in number of bytes) of the data to send.
<b>Result</b>	0                    No error. serErrTimeout      Handshake timeout (such as waiting for CTS to become asserted).
<b>Comments</b>	In the present implementation, SerSend10 blocks until all data is transferred to the UART or a timeout error (if CTS handshaking is enabled) occurs. Future implementations may queue up the request and return immediately, performing transmission in the background. If your software needs to detect when all data has been transmitted, see <a href="#">SerSendWait</a> .  This routine observes the current CTS time out setting if CTS handshaking is enabled (see <a href="#">SerGetSettings</a> and <a href="#">SerSend</a> ).
<b>Compatibility</b>	This function corresponds to the 1.0 version of SerSend.
<b>See Also</b>	<a href="#">SerSend</a> , <a href="#">SerSendWait</a>

## SerSendFlush

<b>Purpose</b>	Discard all data presently in the transmit queue.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerSendFlush (UInt16 refNum)
<b>Parameters</b>	-> refNum            Serial library reference number.
<b>Result</b>	0                    No error.
<b>See Also</b>	<a href="#">SerSend</a> , <a href="#">SerSendWait</a>

## SerSendWait

<b>Purpose</b>	Wait until the serial transmit buffer empties.
<b>Declared In</b>	SerialMgrOld.h
<b>Prototype</b>	Err SerSendWait (UInt16 refNum, Int32 timeout)
<b>Parameters</b>	-> refNum            Serial library reference number. -> timeout           Reserved for future enhancements. Set to (-1) for compatibility.
<b>Result</b>	0                    No error. serErrTimeOut      Handshake timeout (such as waiting for CTS to become asserted).
<b>Comments</b>	SerSendWait blocks until all data is transferred or a timeout error (if CTS handshaking is enabled) occurs. This routine observes the current CTS timeout setting if CTS handshaking is enabled (see <a href="#">SerGetSettings</a> and <a href="#">SerSend</a> ).
<b>See Also</b>	<a href="#">SerSend</a>

## Old Serial Manager

### *Serial Manager Functions*

---

## SerSetReceiveBuffer

- Purpose** Replace the default receive queue. To restore the original buffer, pass `bufSize = 0`.
- Declared In** `SerialMgrOld.h`
- Prototype** `Err SerSetReceiveBuffer (UInt16 refNum, void *bufP, UInt16 bufSize)`
- Parameters**
- > `refNum` Serial library reference number.
  - > `bufP` Pointer to buffer to be used as the new receive queue.
  - > `bufSize` Size of buffer, or 0 to restore the default receive queue.
- Result** Returns 0 if successful.
- Comments** The specified buffer needs to contain 32 extra bytes for serial manager overhead (its size should be your application's requirement plus 32 bytes). The default receive queue must be restored before the serial port is closed. To restore the default receive queue, call [SerSetReceiveBuffer](#) passing 0 (zero) for the buffer size. The serial manager does not free the custom receive queue.

## SerSetSettings

- Purpose** Set the serial port settings; that is, change its attributes.
- Declared In** `SerialMgrOld.h`
- Prototype** `Err SerSetSettings (UInt16 refNum, SerSettingsPtr settingsP)`
- Parameters**
- > `refNum` Serial library reference number.

<-> settingsP    Pointer to the filled in [SerSettingsType](#) structure.

**Result**    0                    No error.  
             serErrNotOpen    The port wasn't open.  
             serErrBadParam Invalid parameter.

**Comments**    The attributes set by this call include the current baud rate, CTS timeout, handshaking options, and data format options. See the definition of the [SerSettingsType](#) structure for more details.

To do 7E1 transmission, OR together:

```
serSettingsFlagBitsPerChar7 |  
serSettingsFlagParityOnM |  
serSettingsFlagParityEvenM |  
serSettingsFlagStopBits1
```

If you're trying to communicate at speeds greater than 19.2 Kbps, you need to use hardware handshaking:

```
serSettingsFlagRTSAutoM | serSettingsFlagCTSAutoM.
```

**See Also**    [SerGetSettings](#)

## **Old Serial Manager**

*Serial Manager Functions*

---

# Serial Link Manager

---

This chapter provides reference material for the serial link manager API. The header file `SerialLinkMgr.h` declares the serial link manager API. For more information on the serial link manager, see the chapter “[Serial Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Serial Link Manager Functions

### SlkClose

<b>Purpose</b>	Close down the serial link manager.
<b>Declared In</b>	<code>SerialLinkMgr.h</code>
<b>Prototype</b>	<code>Err SlkClose (void)</code>
<b>Parameters</b>	None.
<b>Result</b>	0                      No error. <code>slkErrNotOpen</code> The serial link manager was not open.
<b>Comments</b>	When the open count reaches zero, this routine frees resources allocated by serial link manager.

## **SlkCloseSocket**

**Purpose** Closes a socket previously opened with [SlkOpenSocket](#).  
The caller is responsible for closing the communications library used by this socket, if necessary.

**Declared In** SerialLinkMgr.h

**Prototype** Err SlkCloseSocket (UInt16 socket)

**Parameters** socket                      The socket ID to close.

**Result** 0                              No error.  
slkErrSocketNotOpen  
  The socket was not open.

**Comments** SlkCloseSocket frees system resources the serial link manager allocated for the socket. It does not free resources allocated and passed by the client, such as the buffers passed to [SlkSetSocketListener](#); this is the client's responsibility. The caller is also responsible for closing the communications library used by this socket.

**See Also** [SlkOpenSocket](#)

## **SlkFlushSocket**

**Purpose** Flush the receive queue of the communications library associated with the given socket.

**Declared In** SerialLinkMgr.h

**Prototype** Err SlkFlushSocket (UInt16 socket, Int32 timeout)

**Parameters** -> socket                      Socket ID.

-> timeout            Interbyte timeout in system ticks.

**Result**    0                    No error.  
              slkErrSocketNotOpen  
                          The socket wasn't open.

## SlkOpen

**Purpose**     Initialize the serial link manager.

**Declared In**    SerialLinkMgr.h

**Prototype**    Err SlkOpen (void)

**Parameters**    None.

**Result**     0                    No error.  
              slkErrAlreadyOpen  
                          No error.

**Comments**    Initializes the serial link manager, allocating necessary resources. Return codes of 0 (zero) and `slkErrAlreadyOpen` both indicate success. Any other return code indicates failure. The `slkErrAlreadyOpen` function informs the client that someone else is also using the serial link manager. If the serial link manager was successfully opened by the client, the client needs to call [SlkClose](#) when it finishes using the serial link manager.

## SlkOpenSocket

- Purpose** Open a serial link socket and associate it with a communications library. The socket may be a known static socket or a dynamically assigned socket.
- Declared In** SerialLinkMgr.h
- Prototype** `Err SlkOpenSocket (UInt16 portID,  
UInt16 *socketP, Boolean staticSocket)`
- Parameters**
- |                           |  |
|---------------------------|--|
| <code>portID</code>       | Comm library reference number for socket.  |
| <code>socketP</code>      | Pointer to location for returning the socket ID.   |
| <code>staticSocket</code> | If TRUE, <code>*socketP</code> contains the desired static socket number to open. If FALSE, any free socket number is assigned dynamically and opened. |
- Result**
- |                                 |                                |
|---------------------------------|--------------------------------|
| <code>0</code>                  | No error.                      |
| <code>slkErrOutOfSockets</code> | No more sockets can be opened. |
- Comments** The communications library must already be initialized and opened (see [SerOpen](#)). When finished using the socket, the caller must call [SlkCloseSocket](#) to free system resources allocated for the socket. For information about well-known static socket IDs, see [The Serial Link Protocol](#).

## SlkReceivePacket

**Purpose** Receive and validate a packet for a particular socket or for any socket. Check for format and checksum errors.

**Declared In** SerialLinkMgr.h

**Prototype** Err SlkReceivePacket (UInt16 socket, Boolean andOtherSockets, SlkPktHeaderPtr headerP, void\* bodyP, UInt16 bodySize, Int32 timeout)

**Parameters**

-> socket	The socket ID.
-> andOtherSockets	If TRUE, ignore destination in packet header.
<-> headerP	Pointer to the packet header buffer (size of SlkPktHeaderType).
<-> bodyP	Pointer to the packet client data buffer.
-> bodySize	Size of the client data buffer (maximum client data size which can be accommodated).
-> timeout	Maximum number of system ticks to wait for beginning of a packet; -1 means wait forever.

**Result** 0 No error.

slkErrSocketNotOpen  
The socket was not open.

slkErrTimeOut Timed out waiting for a packet.

slkErrWrongDestSocket  
The packet being received had an unexpected destination.

slkErrChecksum Invalid header checksum or packet CRC-16.

slkErrBuffer Client data buffer was too small for packet's client data.

If andOtherSockets is FALSE, this routine returns with an error code unless it gets a packet for the specific socket.

## Serial Link Manager

### Serial Link Manager Functions

---

If `andOtherSockets` is `TRUE`, this routine returns successfully if it sees any incoming packet from the communications library used by `socket`.

**Comments** You may request to receive a packet for the passed socket ID only, or for any open socket which does not have a socket listener. The parameters also specify buffers for the packet header and client data, and a timeout. The timeout indicates how long the receiver should wait for a packet to begin arriving before timing out. If a packet is received for a socket with a registered socket listener, it will be dispatched via its socket listener procedure. On success, the packet header buffer and packet client data buffer is filled in with the actual size of the packet's client data in the packet header's `bodySize` field.

## SlkSendPacket

**Purpose** Send a serial link packet via the serial output driver.

**Declared In** `SerialLinkMgr.h`

**Prototype** `Err SlkSendPacket (SlkPktHeaderPtr headerP,  
SlkWriteDataPtr writeList)`

**Parameters**

<code>&lt;-&gt; headerP</code>	Pointer to the packet header structure with client information filled in (see Comments).
<code>-&gt; writeList</code>	List of packet client data blocks (see Comments).

**Result**

<code>0</code>	No error.
<code>slkErrSocketNotOpen</code>	The socket was not open.
<code>slkErrTimeOut</code>	Handshake timeout.

**Comments** `SlkSendPacket` stuffs the signature, client data size, and the checksum fields of the packet header. The caller must fill in all other packet header fields. If the transaction ID field is set to 0 (zero), the

serial link manager automatically generates and stuffs a new non-zero transaction ID. The array of `SlkWriteDataType` structures enables the caller to specify the client data part of the packet as a list of noncontiguous blocks. The end of list is indicated by an array element with the `size` field set to 0 (zero). This call blocks until the entire packet is sent out or until an error occurs.

## **SlkSetSocketListener**

<b>Purpose</b>	Register a socket listener for a particular socket.						
<b>Declared In</b>	<code>SerialLinkMgr.h</code>						
<b>Prototype</b>	<code>Err SlkSetSocketListener (UInt16 socket, SlkSocketListenPtr socketP)</code>						
<b>Parameters</b>	<table><tr><td><code>-&gt; socket</code></td><td>Socket ID.</td></tr><tr><td><code>-&gt; socketP</code></td><td>Pointer to a <code>SlkSocketListenType</code> structure.</td></tr></table>	<code>-&gt; socket</code>	Socket ID.	<code>-&gt; socketP</code>	Pointer to a <code>SlkSocketListenType</code> structure.		
<code>-&gt; socket</code>	Socket ID.						
<code>-&gt; socketP</code>	Pointer to a <code>SlkSocketListenType</code> structure.						
<b>Result</b>	<table><tr><td><code>0</code></td><td>No error.</td></tr><tr><td><code>slkErrBadParam</code></td><td>Invalid parameter.</td></tr><tr><td><code>slkErrSocketNotOpen</code></td><td>The socket was not open.</td></tr></table>	<code>0</code>	No error.	<code>slkErrBadParam</code>	Invalid parameter.	<code>slkErrSocketNotOpen</code>	The socket was not open.
<code>0</code>	No error.						
<code>slkErrBadParam</code>	Invalid parameter.						
<code>slkErrSocketNotOpen</code>	The socket was not open.						
<b>Comments</b>	<p>Called by applications to set up a socket listener.</p> <p>Since the serial link manager does not make a copy of the <code>SlkSocketListenType</code> structure, but instead saves the passed pointer to it, the structure</p> <ul style="list-style-type: none"><li>• must <b>not</b> be an automatic variable (that is, local variable allocated on the stack)</li><li>• may be a global variable in an application</li><li>• may be a locked chunk allocated from the dynamic heap</li></ul> <p>The <code>SlkSocketListenType</code> structure specifies pointers to the socket listener procedure and the data buffers for dispatching packets destined for this socket. Pointers to two buffers must be</p>						

## Serial Link Manager

### Serial Link Manager Functions

---

specified: the packet header buffer (size of `SlkPktHeaderType`), and the packet body (client data) buffer. The packet body buffer must be large enough for the largest expected client data size. Both buffers may be application global variables or locked chunks allocated from the dynamic heap.

The socket listener procedure is called when a valid packet is received for the socket. Pointers to the packet header buffer and the packet body buffer are passed as parameters to the socket listener procedure.

---

**NOTE:** The application is responsible for freeing the `SlkSocketListenType` structure or the allocated buffers when the socket is closed. The serial link manager doesn't do it.

---

**Compatibility** If [5.0 New Feature Set](#) is present this function is unimplemented.

## SlkSocketPortID

**Purpose** Get the port ID associated with a particular socket; for use with the new serial manager.

**Declared In** `SerialLinkMgr.h`

**Prototype** `ErrSlkSocketPortID (UInt16 socket, UInt16 * portIDP)`

**Parameters**

<code>-&gt; socket</code>	The socket ID.
<code>&lt;-&gt; portIDP</code>	Pointer to location for returning the port ID.

**Result**

<code>0</code>	No error.
<code>slkErrSocketNotOpen</code>	The socket was not open.

**Compatibility** Implemented only if [New Serial Manager Feature Set](#) is present.

## **SlkSocketSetTimeout**

<b>Purpose</b>	Set the interbyte packet receive-timeout for a particular socket.				
<b>Declared In</b>	<code>SerialLinkMgr.h</code>				
<b>Prototype</b>	<code>Err SlkSocketSetTimeout (UInt16 socket, Int32 timeout)</code>				
<b>Parameters</b>	<table><tr><td><code>-&gt; socket</code></td><td>Socket ID.</td></tr><tr><td><code>-&gt; timeout</code></td><td>Interbyte packet receive-timeout in system ticks.</td></tr></table>	<code>-&gt; socket</code>	Socket ID.	<code>-&gt; timeout</code>	Interbyte packet receive-timeout in system ticks.
<code>-&gt; socket</code>	Socket ID.				
<code>-&gt; timeout</code>	Interbyte packet receive-timeout in system ticks.				
<b>Result</b>	<table><tr><td><code>0</code></td><td>No error.</td></tr><tr><td><code>slkErrSocketNotOpen</code></td><td>The socket was not open.</td></tr></table>	<code>0</code>	No error.	<code>slkErrSocketNotOpen</code>	The socket was not open.
<code>0</code>	No error.				
<code>slkErrSocketNotOpen</code>	The socket was not open.				

## **Serial Link Manager**

*Serial Link Manager Functions*

---

# Telephony Basic Services

---

This chapter provides reference material for the Telephony API, which you can use to interface with telephone systems and equipment. This chapter discusses the following topics:

- [Telephony Data Structures](#)
- [Telephony Constants](#)
- [Telephony Functions](#)
- [Feature Support Functions](#)

The header file `TelephonyMgr.h` declares the telephony manager API. The header file `TelephonyMgrType.h` declares the data structures that you use with the telephony manager API.

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Service Types

The telephony API organizes functions within sets called **service sets**. Each service set contains a related set of functions that may or may not be available on a particular mobile device or network. You can use the [TelIs<ServiceSet>Available](#) function to determine if a service set is supported in the current environment, and you can use the [TelIs<FunctionName>Supported](#) to determine if a specific function is supported in the current environment.

## Telephony Basic Services

### Telephony Service Types

---

The telephony API documentation has been split into several chapters. Each chapter covers one or more of the service sets, as shown in [Table 68.1](#)

**Table 68.1 Telephony service types**

Service prefix	Functionality	Chapter	Description
Tel	Basic	<a href="#">Chapter 68</a> , “ <a href="#">Telephony Basic Services</a> .”	Basic functions that are always available.
TelCfg	Configuration	<a href="#">Chapter 69</a> , “ <a href="#">Telephony Security and Configuration</a> .”	Allows configuration of the phone, including Short Message Services (SMS) configuration.
TelDtc	Data calls	<a href="#">Chapter 71</a> , “ <a href="#">Telephony Calls</a> .”	Functions for handling data calls.
TelEmc	Emergency calls	<a href="#">Chapter 71</a> , “ <a href="#">Telephony Calls</a> .”	Functions for handling emergency calls.
TelInf	Information	<a href="#">Chapter 68</a> , “ <a href="#">Telephony Basic Services</a> .”	Functions for retrieving information about the phone.
TelNwk	Network	<a href="#">Chapter 70</a> , “ <a href="#">Telephony Network</a> .”	Provides network oriented services, including authorization, signal level, search mode, and related operations.
TelOem	OEM	<a href="#">Chapter 68</a> , “ <a href="#">Telephony Basic Services</a> .”	Provides OEMs with the ability to incorporate custom functionality.
TelPhb	Phone book	<a href="#">Chapter 73</a> , “ <a href="#">Telephony Phone Book</a> .”	Functions for managing the phone book.

**Table 68.1 Telephony service types (*continued*)**

<b>Service prefix</b>	<b>Functionality</b>	<b>Chapter</b>	<b>Description</b>
TelPow	Power	<a href="#">Chapter 68</a> , “ <a href="#">Telephony Basic Services</a> .”	Provides access to power supply level.
TelSms	Short Message Service	<a href="#">Chapter 72</a> , “ <a href="#">Telephony SMS</a> .”	Addresses the SMS, including functions for reading, sending, replying to, and deleting short messages.
TelSnd	Sound	<a href="#">Chapter 68</a> , “ <a href="#">Telephony Basic Services</a> .”	Functions for playing key tones on and muting the phone.
TelSpc	Speech calls	<a href="#">Chapter 71</a> , “ <a href="#">Telephony Calls</a> .”	Function for handling voice calls, including dual tone modulated frequency (DTMF) sounds.
TelSty	Security	<a href="#">Chapter 69</a> , “ <a href="#">Telephony Security and Configuration</a> .”	Supports PIN code management for access to phone and Subscriber Identity Module (SIM) security-related features.

---

## Telephony Data Structures

This section describes the data structures used with the basic services portion of the telephony API.

### TelEventType

The [TelGetEvent](#) and [TelGetTelephonyEvent](#) functions both return a `TelEventType` structure to provide information about a telephony-related event.

You call the [TelGetEvent](#) function to retrieve telephony and other events.

## Telephony Basic Services

### Telephony Data Structures

---

You call the [TelGetTelephonyEvent](#) function to retrieve only telephony events. This function does not consume non-telephony events.

```
typedef struct _TelEventType
{
    eventsEnum    eType;
    Boolean       penDown;
    UInt8         tapCount;
    Int16         screenX;
    Int16         screenY;
    UInt16        functionId;
    UInt16        transId;
    MemPtr        *paramP;
    Err           returnCode;
} TelEventType
```

#### Field Descriptions

eType	One of the <a href="#">eventsEnum</a> constants. Specifies the type of the event.
penDown	true if the pen was down at the time of the event, and false if the pen was up.  Note that this field is not filled in for telephony events.
tapCount	The number of taps received at this location. This value is used mainly by text fields. When the user taps in a text field, two taps selects a word, and three taps selects the entire line.  Note that this field is not filled in for telephony events.

<code>screenX</code>	Window-relative position of the pen in pixels (number of pixels from the left bound of the window).  Note that this field is not filled in for telephony events.
<code>screenY</code>	Window-relative position of the pen in pixels (number of pixels from the top left of the window).  Note that this field is not filled in for telephony events.
<code>functionId</code>	The ID of the message associated with the function call, which specifies the telephony manager function that generated this event.
<code>transId</code>	The transaction ID that was associated with this asynchronous function call.
<code>paramP</code>	A pointer to a parameter structure that was passed when an asynchronous call was made.
<code>returnCode</code>	The return code of the asynchronously called function. The value of this field is <code>errNone</code> if the function succeeded, or an error code if the function failed.

Note that the first five fields of the `TelEventType` structure are the same as the first five fields of the [Event Type](#) structure, which is described in [Chapter 2, “Palm OS Events.”](#)

## TelCallStateType

The [TelGetCallState](#) function uses the `TelCallState` structure to retrieve information about the current state of the connected phone.

```
typedef struct _TelGetCallStateType
{
```

## Telephony Basic Services

### Telephony Data Structures

---

```
    UInt8    state;  
    UInt8    callType;  
    UInt8    callServiceType;  
    UInt8    numberSize;  
    Char     *number;  
} TelGetCallStateType
```

#### Field Descriptions

- |    |                 |  |
|----|-----------------|--|
| <- | state           | Filled in with one of the <a href="#">Telephone Call State Constants</a> , which indicates the current state of the telephone call.                    |
| <- | callType        | Filled in with one of the <a href="#">Telephone Call Type Constants</a> , which indicates the call type of the current telephone call.                 |
| <- | callServiceType | Filled in with one of the <a href="#">Telephone Call Service Type Constants</a> , which indicates the call service type of the current telephone call. |

<->     numberSize           The size of the number string buffer. When the structure is used as an input parameter, this is the allocated size, in bytes, of the buffer.

Upon return, this is the actual size of the string, including the null terminator character. If the number buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the data, and the function using this structure generates a `telErrBufferSize` error.

<-       number               A buffer into which the telephone number string is stored.

When the structure describes an incoming telephone call, this is the incoming telephone number. When the structure describes an outgoing telephone call, this is the telephone number that has been called.

Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

## TelInfGetformationType

The [TelInfGetInformation](#) function uses the `TelInfGetInformationType` structure to retrieve information about the phone with which you are communicating.

```
typedef struct _TelInfGetInformationType
{
    UInt8      infoType;
    UInt8      size;
    UInt8      *value;
} TelInfGetInformationType
```

## Telephony Basic Services

### Telephony Data Structures

---

#### Field Descriptions

->	infoType	The type of information to retrieve. This must be one of the <a href="#">Information Type Constants</a> .
<->	size	The size of the value buffer. When the structure is used as an input parameter, this is the allocated size, in bytes, of the buffer.  Upon return, this is the actual size of the buffer. If the value buffer is too small to contain all of the retrieved information, this field is assigned the entire length of the data, and the function using this structure generates a <code>telErrBufferSize</code> error.
<-	value	A buffer into which the information is stored.

#### TelOemCallType

You use the `TelOemCallType` to specify a [TelOemCall](#) function.

```
typedef struct _TelOemCallType
{
    UInt32  OemID;
    UInt8   funcID;
    void    *paramP;
} TelOemCallType
```

#### Field Descriptions

->	OemID	The unique ID of the OEM function set.
->	funcID	The ID of the function within the OEM function set.
<->	paramP	A pointer to a parameter block that is passed to the OEM function. The OEM function might modify some of the fields in the parameter block.

#### TelSendCommandStringType

The [TelSendCommandString](#) function uses the `TelSendCommandStringType` structure to send a command string.

```
typedef struct _TelSendCommandStringType
{
    Char    *commandString;
    Char    *resultString;
    UInt16  resultSize;
    UInt32  timeOut;
} TelSendCommandStringType
```

### Field Descriptions

- |     |               |  |
|-----|---------------|--|
| ->  | commandString | The command string to send.  |
| <-  | resultString  | The result string.   |
| <-> | resultSize    | The size of the resultString string buffer. When the structure is used as an input parameter, this is the allocated size, in bytes, of the buffer.<br><br>Upon return, this is the actual size of the string, including the null terminator character. If the resultString buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the data, and the function using this structure generates a telErrBufferSize error. |
| ->  | timeOut       | The number of milliseconds before timing out.  |

### TelSndPlayKeyToneType

The [TelSndPlayKeyTone](#) function uses the TelSndPlayKeyToneType structure to specify a key tone.

```
typedef struct _TelSndPlayKeyToneType
{
    UInt8    keycode;
    UInt8    type;
} TelSndPlayKeyToneType
```

## Telephony Basic Services

### Telephony Constants

---

#### Field Descriptions

- > `keycode`                      The keycode of the key tone to play. This must be one of the [Keycode Constants](#).
- > `type`                              The tone type. This must be one of the [Key Sound Type Constants](#).

## Telephony Constants

This section describes the data structures used with the basic services portion of the telephony API, which include the following constant types:

- [Battery Status Constants](#)
- [Telephone Call State Constants](#)
- [Telephone Call Type Constants](#)
- [Telephone Call Service Type Constants](#)
- [Error Code Constants](#)
- [Information Type Constants](#)
- [Keycode Constants](#)
- [Key Sound Type Constants](#)
- [Message Identifier Constants](#)
- [Service Set Constants](#)

### Battery Status Constants

The battery status constants provide information about the phone's battery.

---

Constant	Value	Description
<code>kTelPowBatteryPowered</code>	0	The phone is powered by a battery.
<code>kTelPowBatteryNotPowered</code>	1	The phone has a battery connected to it, but is not using that battery.

---

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelPowNobattery</code>	2	The phone does not have a battery connected to it.
<code>kTelPowBatteryFault</code>	3	The phone has a recognized power fault; calls are currently inhibited.

### Telephone Call State Constants

The [TelCallStateType](#) structure uses the telephone call state constants to encode the current state of the connected telephone call.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelCallIdle</code>	0x00	The connection is idle.
<code>kTelCallConnecting</code>	0x01	A telephone call is currently connecting.
<code>kTelCallConnected</code>	0x02	A telephone call is currently connected.
<code>kTelCallRedial</code>	0x03	A telephone call is being re-dialed.
<code>kTelCallIncoming</code>	0x04	A telephone call is currently incoming.
<code>kTelCallIncomingAck</code>	0x05	An incoming telephone call is currently being acknowledged.
<code>kTelCallDisconnecting</code>	0x06	A telephone call is being disconnected.

### Telephone Call Type Constants

The [TelCallStateType](#) structure uses the telephone call type constants to encode the type of the current telephone call.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelCallTypeOutgoing</code>	0x00	An outgoing telephone call.
<code>kTelCallTypeIncoming</code>	0x01	An incoming telephone call.

## Telephony Basic Services

### Telephony Constants

---

#### Telephone Call Service Type Constants

The [TelCallStateType](#) structure uses the telephone call service type constants to encode the service type of the current telephone call.

Constant	Value	Description
kTelCallServiceVoice	0x00	A voice telephone call.
kTelCallServiceData	0x01	A data telephone call.

#### Error Code Constants

The telephony manager functions return the error code constants shown in the following table to indicate their status.

Constant	Description
telErrBufferSize	One of the buffers used to retrieve data is too small.
telErrCodingScheme	The coding scheme specified for the short message is not valid.
telErrCommandFailed	The specified command could not be performed by the phone. Check the phone driver.
telErrEntryNotFound	The specified entry was not found.
telErrFeatureNotSupported	The specified feature is not supported by the phone or network.
telErrGenericDrvNotFound	The generic driver could not be found.
telErrInvalidAppId	The specified application ID is not valid.
telErrInvalidDial	The dial string contains an invalid character.
telErrInvalidIndex	The index specified for accessing a value in storage is incorrect.
telErrInvalidParameter	A parameter is not valid.
telErrInvalidString	The text string contains an invalid character.

<b>Constant</b>	<b>Description</b>
<code>telErrLibStillInUse</code>	The shared lib is currently being used by another application. Do not unload it!
<code>telErrMemAllocation</code>	A memory allocation error occurred.
<code>telErrMsgAllocation</code>	The telephony messages pool is empty; a message could not be allocated.
<code>telErrNetworkTimeOut</code>	The network did not reply within the standard time delay amount.
<code>telErrNoNetwork</code>	There is no network available.
<code>telErrNoSIMInserted</code>	The SIM card is not inserted.
<code>telErrNoSpecificDrv</code>	A specific driver was not specified.
<code>telErrNotInstalled</code>	The shared library could not be installed.
<code>telErrPassword</code>	The password is not correct.
<code>telErrPhoneCodeRequired</code>	A phone code is required.
<code>telErrPhoneComm</code>	The communication link with the phone is down.
<code>telErrPhoneMemAllocation</code>	The phone's memory is full.
<code>telErrPhoneMemFailure</code>	The phone encountered a memory error.
<code>telErrPhoneNumber</code>	One of the following errors has occurred: the phone number is wrong, the SMS center is not valid, or the receiver phone number is wrong for the SMS.
<code>telErrPhoneReply</code>	The phone reply syntax is incorrect. Check the phone driver.
<code>telErrPhoneToSIMPINRequired</code>	A phone 2 SIM PIN code is required
<code>telErrPIN2Required</code>	A PIN2 code is required.
<code>telErrPINRequired</code>	A PIN code is required.
<code>telErrPUK2Required</code>	A PUK2 code is required.

## Telephony Basic Services

### Telephony Constants

---

Constant	Description
telErrPUKRequired	A PUK code is required.
telErrResultBusyResource	A resource is busy.
telErrResultTimeOut	A time-out was reached.
telErrResultUserCancel	The user cancelled the action.
telErrSecurity	Access to the phone was not granted.
telErrSettings	The telephony settings are not valid; this is due to 1) the Phone Panel preferences do not exist, or 2) the Telephony Profile is not correctly set.
telErrSIMBusy	The SIM could not reply.
telErrSIMFailure	The SIM is not working properly.
telErrSIMWrong	The SIM is not accepted by the phone.
telErrSpcCallError	The voice telephone call encountered an error.
telErrSpcLineIsBusy	The voice telephone call failed.
telErrSpcLineIsReleased	The voice telephone call has been released.
telErrSpecificDrvNotFound	The specified driver could not be found.
telErrTooManyApps	The applications table is full.
telErrTTaskNotFound	The Telephony Task could not be found.
telErrTTaskNotRunning	The Telephony Task is not running.
telErrUnavailableValue	The requested value can not be retrieved at the specified time. This is usually due to a <code>TelSpcGetCallerNumber</code> request when there is no active line.
telErrUnknown	An unknown telephony manager error occurred.
telErrValidityPeriod	The validity period specified for the short message is not valid.

<b>Constant</b>	<b>Description</b>
<code>telErrValueStale</code>	The information could not be retrieved; a copy of the most recently retrieved value has been returned instead.
<code>telErrVersion</code>	The shared library version does not match the version associated with the application.

---

### Information Type Constants

The [TelInfGetformationType](#) structure uses the information type constants to encode the type of information to retrieve about the phone.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelInfPhoneBrand</code>	0	The brand name of the phone.
<code>kTelInfPhoneModel</code>	1	The model number of the phone.
<code>kTelInfPhoneRevision</code>	2	The revision number of the phone.

---

### Keycode Constants

The [TelSndPlayKeyToneType](#) structure uses the keycode constants to specify the key tone to play.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTel0Key</code>	0x00	The 0 key on the phone keypad.
<code>kTel1Key</code>	0x01	The 1 key on the phone keypad.
<code>kTel2Key</code>	0x02	The 2 key on the phone keypad.
<code>kTel3Key</code>	0x03	The 3 key on the phone keypad.
<code>kTel4Key</code>	0x04	The 4 key on the phone keypad.
<code>kTel5Key</code>	0x05	The 5 key on the phone keypad.
<code>kTel6Key</code>	0x06	The 6 key on the phone keypad.
<code>kTel7Key</code>	0x07	The 7 key on the phone keypad.

---

## Telephony Basic Services

### Telephony Constants

---

Constant	Value	Description
kTel8Key	0x08	The 8 key on the phone keypad.
kTel9Key	0x09	The 9 key on the phone keypad.
kTelPoundKey	0x23	The POUND(#) key on the phone keypad.
kTelStarKey	0x2A	The STAR(*) key on the phone keypad.
kTelSendKey	0x45	The SEND key on the phone keypad.
kTelEndKey	0x46	The END key on the phone keypad.
kTelClrKey	0x47	The CLEAR key on the phone keypad.
kTelSaveKey	0x48	The SAVE key on the phone keypad.

---

### Key Sound Type Constants

The [TelSndPlayKeyToneType](#) structure uses the key sound type constants to specify how the tone is played.

Constant	Value	Description
kTelSndSingleTone	0x00	Play the key sound as a single tone.
kTelSndMultiTones	0x01	Play the key sound as a multiple tones.

---

### Message Identifier Constants

The message identifier constants are used with asynchronous calls to identify which telephony function is being or has been called. The `TelMessages` enumeration defines a constant for each function name.

Each message identifier constant has the form:

`kfunctionNameMessage`

where *functionName* is replaced by a function name.

The following table shows examples of message identifier constants. For a complete list, see the `TelephonyMgr.h` file.

<b>Constant</b>	<b>Function</b>
<code>kTelGetCallStateMessage</code>	<a href="#">TelGetCallState</a>
<code>kTelNwkSelectNetworkMessage</code>	<a href="#">TelNwkSelectNetwork</a>
<code>kTelSmsReadMessageMessage</code>	<a href="#">TelSmsReadMessage</a>

## Service Set Constants

The service set constants specify a set of API services.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelNwkServiceId</code>	0	The network service set.
<code>kTelStyServiceId</code>	1	The security service set.
<code>kTelPowServiceId</code>	2	The power service set.
<code>kTelCfgServiceId</code>	3	The configuration service set.
<code>kTelSmsServiceId</code>	4	The short message service set.
<code>kTelEmcServiceId</code>	5	The emergency telephone call service set.
<code>kTelSpcServiceId</code>	6	The speech telephone call service set.
<code>kTelDtcServiceId</code>	7	The data telephone call service set.
<code>kTelPhbServiceId</code>	8	The phone book service set.
<code>kTelOemServiceId</code>	9	The OEM service set.
<code>kTelSndServiceId</code>	10	The sound service set.
<code>kTelInfServiceId</code>	11	The information service set.

## Telephony Functions

This section describes the functions used with the basic services portion of the telephony API.

## TelCancel

<b>Purpose</b>	Cancels an asynchronous function call.								
<b>Declared In</b>	<code>TelephonyMgr.h</code>								
<b>Prototype</b>	<pre>Err TelCancel(UInt16 iRefnum, TelAppID iAppId,               UInt16 iTransId, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; <code>iRefnum</code></td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; <code>iAppId</code></td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>-&gt; <code>iTransId</code></td><td>The transaction ID associated with the function that you are cancelling.</td></tr><tr><td>&lt;-&gt; <code>ioTransIdP</code></td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> <code>iRefnum</code>	The telephony manager library reference number.	-> <code>iAppId</code>	The telephone application attachment identifier for your application.	-> <code>iTransId</code>	The transaction ID associated with the function that you are cancelling.	<-> <code>ioTransIdP</code>	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> <code>iRefnum</code>	The telephony manager library reference number.								
-> <code>iAppId</code>	The telephone application attachment identifier for your application.								
-> <code>iTransId</code>	The transaction ID associated with the function that you are cancelling.								
<-> <code>ioTransIdP</code>	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function call was successfully cancelled. Returns the <code>telErrCommandFailed</code> error code if the function call could not be cancelled.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td><code>returnCode</code></td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>functionId</code></td><td><code>kTelUrqCancelMessage</code></td></tr><tr><td><code>paramId</code></td><td>Points to the unsigned integer value passed to this function in the <code>iTransId</code> parameter.</td></tr></table>	<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.	<code>transId</code>	The transaction ID of the operation.	<code>functionId</code>	<code>kTelUrqCancelMessage</code>	<code>paramId</code>	Points to the unsigned integer value passed to this function in the <code>iTransId</code> parameter.
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.								
<code>transId</code>	The transaction ID of the operation.								
<code>functionId</code>	<code>kTelUrqCancelMessage</code>								
<code>paramId</code>	Points to the unsigned integer value passed to this function in the <code>iTransId</code> parameter.								

**Comments** This function cancels a pending asynchronous function call. You can cancel any asynchronous call except for an asynchronous call to the `TelCancel` function.

The function call that is cancelled returns the `telErrUserCancel` error code.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelClose

**Purpose** Close the shared library.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelClose(UInt16 iRefnum, TelAppID iAppId)`

**Parameters**

-> <code>iRefnum</code>	The telephony manager library reference number.
-> <code>iAppId</code>	The telephone application attachment identifier for your application.

**Result** Returns an error code, or error none if the library was successfully closed. If the library is currently being used by another application, this function returns the `telErrLibStillInUse` error code.

**Comments** Call this function when you are done with the telephony manager. You can only use this function synchronously.

If no other application is using the telephony manager, this function stops the Telephony task and releases any resources used by the telephony manager.

**See Also** [TelOpen](#)

## Telephony Basic Services

### Telephony Functions

---

## TelClosePhoneConnection

**Purpose** Closes down communications with the connected phone.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelClosePhoneConnection(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` A `NULL` pointer.

`functionId` `kTelUrqClosePhoneConnectionMessage`

**Comments** Call this function when you have finished communications with the phone and are ready to disconnect from it.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelOpenPhoneConnection](#)

## **TelGetCallState**

**Purpose**            Retrieves the current telephone call state information.

**Declared In**      `TelephonyMgr.h`

**Prototype**        `Err TelGetCallState(UInt16 iRefnum,  
TelAppID iAppId, TelGetCallStateType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;-&gt; ioParamP</code>	A pointer to a <a href="#">TelCallStateType</a> structure that describes the state of the current telephone call.  On input, the <code>numberSize</code> field of this structure specifies the allocated size of the number buffer. Upon return, the <code>numberSize</code> field specifies the actual size of the telephone number, even if it was truncated to fit into the buffer.
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.  If this parameter is not <code>NULL</code> , the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**    Returns `errNone` if the function was successful or returns an error code if not successful.

## Telephony Basic Services

### Telephony Functions

---

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelCallStateType</a> structure passed to this function in the <code>ioCallState</code> parameter.
<code>functionId</code>	<code>kTelGetCallStateMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments** This function retrieves information about the current telephone call state of the connection with the phone, and stores that information into the supplied [TelCallStateType](#) structure.

The current incoming or outgoing telephone call number is stored into the `number` field of the [TelCallStateType](#) structure referenced by `ioCallStateP`. If the `number` field buffer is too small to contain the complete telephone number, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `numberSize` field of the structure is always updated to contain the actual size of the complete telephone number.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcAcceptCall](#), [TelSpcCallNumber](#)

## TelGetEvent

<b>Purpose</b>	Retrieves events for applications that use the telephony manager.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>void TelGetEvent(UInt16 iRefnum, TelAppID iAppId, EventPtr oEventP, Int32 iTimeout)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;- oEventP</td><td>A pointer to a <a href="#">TelEventType</a> structure. Upon return, the structure contains the event information, which you should use as described in the Comments section.</td></tr><tr><td>-&gt; iTimeout</td><td>Maximum number of ticks to wait before an event is returned (<code>evtWaitForever</code> means wait indefinitely).</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<- oEventP	A pointer to a <a href="#">TelEventType</a> structure. Upon return, the structure contains the event information, which you should use as described in the Comments section.	-> iTimeout	Maximum number of ticks to wait before an event is returned ( <code>evtWaitForever</code> means wait indefinitely).
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<- oEventP	A pointer to a <a href="#">TelEventType</a> structure. Upon return, the structure contains the event information, which you should use as described in the Comments section.								
-> iTimeout	Maximum number of ticks to wait before an event is returned ( <code>evtWaitForever</code> means wait indefinitely).								
<b>Result</b>	Returns nothing.								
<b>Comments</b>	<p>This function retrieves both telephony and standard Palm OS® events. You must call this function to retrieve events in any application that is running in the UI task and using the telephony manager.</p> <p>Upon return from this function, you need to test the type of the event by examining the <code>oEventP-&gt;type</code> field. If the event type is a telephony event, then you need to cast the pointer as follows to access the fields:</p> <pre style="margin-left: 40px;">TelEventType *telEventP =                     (TelEventType *)oEventP;</pre> <p>This function calls both the <a href="#">EvtGetEvent</a> and <a href="#">TelGetTelephonyEvent</a> functions to retrieve the next event for your application.</p>								

## Telephony Basic Services

### Telephony Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [EvtGetEvent](#), [TelGetTelephonyEvent](#)

## TelGetTelephonyEvent

**Purpose** Retrieves telephony events only.

**Declared In** `TelephonyMgr.h`

**Prototype**  
`void TelGetTelephonyEvent (UInt16 iRefnum,  
TelAppID iAppId, EventPtr oEventP,  
Int32 iTimeout)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;- oEventP</code>	A pointer to a <a href="#">TelEventType</a> structure. Upon return, the structure contains the event information.
<code>-&gt; iTimeout</code>	Maximum number of ticks to wait before an event is returned ( <code>evtWaitForever</code> means wait indefinitely).

**Result** Returns nothing.

**Comments** Use this function instead of the [TelGetEvent](#) function when you only want to process telephony events.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [EvtGetEvent](#), [TelGetEvent](#)

## TelInfGetInformation

<b>Purpose</b>	Retrieve brand, model, and revision information for the phone.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	<pre>Err TelInfGetInformation(UInt16 iRefnum, TelAppID iAppId, TelInfGetInformationType *ioParamP, UInt16 *ioTransIdP)</pre>
<b>Parameters</b>	<p>-&gt; iRefnum      The telephony manager library reference number.</p> <p>-&gt; iAppId      The telephone application attachment identifier for your application.</p> <p>&lt;-&gt; ioParamP    A pointer to a <a href="#">TelInfGetformationType</a> structure.</p> <p>On input, the <code>infoType</code> field of the structure contains the type of information that you want retrieved. The <code>size</code> field of this structure specifies the allocated size of the <code>value</code> buffer. Upon return, the <code>size</code> field specifies the actual size of the information that was retrieved, even if it was truncated to fit into the buffer.</p> <p>&lt;-&gt; ioTransIdP    Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.</p> <p>If this parameter is not <code>NULL</code>, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p>
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:

## Telephony Basic Services

### Telephony Functions

---

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelInfGetformationType</a> structure passed to this function in the <code>ioInfoP</code> parameter.
<code>functionId</code>	<code>kTelInfGetInformationMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### Comments

Call this function to retrieve information about the currently connected phone.

The retrieved information is stored into the `value` field of the [TelInfGetformationType](#) referenced by `ioInfoP` structure. If the `value` field buffer is too small to contain the complete information, the value is truncated and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the retrieved information.

Before using this function, you should verify that it is available by calling the [TelIsInfServiceAvailable](#) macro.

#### Compatibility

Implemented only if [4.0 New Feature Set](#) is present.

## **TellsCfgServiceAvailable**

<b>Purpose</b>	A macro that determines if the configuration service set is available in the current environment.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<code>TelIsCfgServiceAvailable (iRefnum, iAppId, ioTransIdP)</code>								
<b>Parameters</b>	<table><tr><td style="vertical-align: top;"><code>-&gt; iRefnum</code></td><td>The telephony manager library reference number.</td></tr><tr><td style="vertical-align: top;"><code>-&gt; iAppId</code></td><td>The telephone application attachment identifier for your application.</td></tr><tr><td style="vertical-align: top;"><code>&lt;-&gt; ioTransIdP</code></td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	<code>-&gt; iRefnum</code>	The telephony manager library reference number.	<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.	<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
<code>-&gt; iRefnum</code>	The telephony manager library reference number.								
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.								
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td style="vertical-align: top;"><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td style="vertical-align: top;"><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td style="vertical-align: top;"><code>paramP</code></td><td><code>kTelCfgServiceId</code></td></tr><tr><td style="vertical-align: top;"><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelCfgServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelCfgServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	You need to call this macro before calling any function in the configuration service set, which is the family of functions that begin with the <code>TelCfg</code> prefix.								

## Telephony Basic Services

### Telephony Functions

---

The configuration service set functions are documented in [Chapter 72, “Telephony SMS.”](#)

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## TellsDtcServiceAvailable

**Purpose** A macro that determines if the data calls service set is available in the current environment.

**Declared In** `TelephonyMgr.h`

**Prototype** `TelIsDtcServiceAvailable (iRefnum, iAppId, ioTransIdP)`

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` if the service set is available, or an error code if not.

`transId` The transaction ID of the operation.

## Telephony Basic Services

### Telephony Functions

---

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone if the service set is available, or an error code if not.
transId	The transaction ID of the operation.
paramP	kTelEmcServiceId
functionId	kTelUrqIsServiceAvailableMessage

**Comments** You need to call this macro before calling any function in the emergency calls service set, which is the family of functions that begin with the TelEmc prefix.

The emergency calls service set functions are documented in [Chapter 71, "Telephony Calls."](#)

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## TellsInfServiceAvailable

**Purpose** A macro that determines if the information service set is available in the current environment.

**Declared In** TelephonyMgr.h

**Prototype** TelIsInfServiceAvailable (iRefnum, iAppId, ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:  <table><tr><td><code>returnCode</code></td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td><code>transId</code></td><td>The transaction ID of the operation.</td></tr><tr><td><code>paramP</code></td><td><code>kTelInfServiceId</code></td></tr><tr><td><code>functionId</code></td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.	<code>transId</code>	The transaction ID of the operation.	<code>paramP</code>	<code>kTelInfServiceId</code>	<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>
<code>returnCode</code>	<code>errNone</code> if the service set is available, or an error code if not.								
<code>transId</code>	The transaction ID of the operation.								
<code>paramP</code>	<code>kTelInfServiceId</code>								
<code>functionId</code>	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	You need to call this macro before calling any function in the information service set, which is the family of functions that begin with the <code>TelInf</code> prefix.  The information service set functions are documented in this chapter.								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported</a>								

## TellsNwkServiceAvailable

<b>Purpose</b>	A macro that determines if the network service set is available in the current environment.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<code>TelIsNwkServiceAvailable (iRefnum, iAppId, ioTransIdP)</code>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone if the service set is available, or an error code if not.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>kTelNwkServiceId</td></tr><tr><td>functionId</td><td>kTelUrqIsServiceAvailableMessage</td></tr></table>	returnCode	errNone if the service set is available, or an error code if not.	transId	The transaction ID of the operation.	paramP	kTelNwkServiceId	functionId	kTelUrqIsServiceAvailableMessage
returnCode	errNone if the service set is available, or an error code if not.								
transId	The transaction ID of the operation.								
paramP	kTelNwkServiceId								
functionId	kTelUrqIsServiceAvailableMessage								
<b>Comments</b>	You need to call this macro before calling any function in the network service set, which is the family of functions that begin with the <code>TelNwk</code> prefix.								

The network service set functions are documented in [Chapter 70, “Telephony Network.”](#)

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## **TellsOemServiceAvailable**

**Purpose** A macro that determines if the OEM service set is available in the current environment.

**Declared In** `TelephonyMgr.h`

**Prototype** `TelIsOemServiceAvailable (iRefnum, iAppId, ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.  If this parameter is not <code>NULL</code> , the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` if the service set is available, or an error code if not.

`transId` The transaction ID of the operation.

## Telephony Basic Services

### Telephony Functions

---

paramP            kTelOemServiceId  
functionId        kTelUrqIsServiceAvailableMessage

**Comments**     You need to call this macro before calling any function in the OEM service set, which is the family of functions that begin with the TelOem prefix.

The OEM service set functions are documented in this chapter.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelIs<FunctionName>Supported](#)

## TellsPhbServiceAvailable

**Purpose**            A macro that determines if the phone book service set is available in the current environment.

**Declared In**     TelephonyMgr.h

**Prototype**        TelIsPhbServiceAvailable (iRefnum, iAppId,  
ioTransIdP)

**Parameters**

- > iRefnum            The telephony manager library reference number.
- > iAppId             The telephone application attachment identifier for your application.
- <-> ioTransIdP        Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**    Returns errNone if the service set is available, or an error code if not.

<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:  returnCode      errNone if the service set is available, or an error code if not.  transId          The transaction ID of the operation.  paramP          kTelPhbServiceId  functionId      kTelUrqIsServiceAvailableMessage
<b>Comments</b>	You need to call this macro before calling any function in the phone book service set, which is the family of functions that begin with the TelPhb prefix.  The phone book service set functions are documented in <a href="#">Chapter 73</a> , " <a href="#">Telephony Phone Book</a> ."
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">TelIs&lt;FunctionName&gt;Supported</a>

## TellsPhoneConnected

<b>Purpose</b>	Determines if a phone is connected.
<b>Declared In</b>	TelephonyMgr.h
<b>Prototype</b>	Err TelIsPhoneConnected(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)
<b>Parameters</b>	-> iRefnum      The telephony manager library reference number.  -> iAppId      The telephone application attachment identifier for your application.  <-> ioTransIdP Set the value of this parameter to NULL to cause the function to execute synchronously.

## Telephony Basic Services

### Telephony Functions

---

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`            A `NULL` pointer.

`functionId`        `kTelUrqIsPhoneConnectedMessage`

**Comments** Call this function to determine if there is currently a phone connected.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TellsPowServiceAvailable

**Purpose** A macro that determines if the power services set is available in the current environment.

**Declared In** `TelephonyMgr.h`

**Prototype** `TelIsPowServiceAvailable (iRefnum, iAppId, ioTransIdP)`

**Parameters** `-> iRefnum`      The telephony manager library reference number.

`-> iAppId`          The telephone application attachment identifier for your application.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` if the service set is available, or an error code if not.

`transId`          The transaction ID of the operation.

`paramP`           `kTelPowServiceId`

`functionId`      `kTelUrqIsServiceAvailableMessage`

**Comments** You need to call this macro before calling any function in the power service set, which is the family of functions that begin with the `TelPow` prefix.

The power service set functions are documented in this chapter.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## TellsSmsServiceAvailable

<b>Purpose</b>	A macro that determines if the Short Message Service (SMS) service set is available in the current environment.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<code>TelIsSmsServiceAvailable (iRefnum, iAppId, ioTransIdP)</code>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the service set is available, or an error code if not.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td><code>errNone</code> if the service set is available, or an error code if not.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td><code>kTelSmsServiceId</code></td></tr><tr><td>functionId</td><td><code>kTelUrqIsServiceAvailableMessage</code></td></tr></table>	returnCode	<code>errNone</code> if the service set is available, or an error code if not.	transId	The transaction ID of the operation.	paramP	<code>kTelSmsServiceId</code>	functionId	<code>kTelUrqIsServiceAvailableMessage</code>
returnCode	<code>errNone</code> if the service set is available, or an error code if not.								
transId	The transaction ID of the operation.								
paramP	<code>kTelSmsServiceId</code>								
functionId	<code>kTelUrqIsServiceAvailableMessage</code>								
<b>Comments</b>	You need to call this macro before calling any function in the SMS service set, which is the family of functions that begin with the <code>TelSms</code> prefix.								

The SMS service set functions are documented in [Chapter 72](#), “[Telephony SMS](#).”

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## **TellsSndServiceAvailable**

**Purpose** A macro that determines if the sound service set is available in the current environment.

**Declared In** `TelephonyMgr.h`

**Prototype** `TelIsSndServiceAvailable (iRefnum, iAppId, ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.  If this parameter is not <code>NULL</code> , the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` if the service set is available, or an error code if not.

`transId` The transaction ID of the operation.

## Telephony Basic Services

### Telephony Functions

---

paramP            kTelSndServiceId  
functionId        kTelUrqIsServiceAvailableMessage

**Comments**    You need to call this macro before calling any function in the sound service set, which is the family of functions that begin with the TelSnd prefix.

The sound service set functions are documented in this chapter.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelIs<FunctionName>Supported](#)

## TellsPcServiceAvailable

**Purpose**            A macro that determines if the speech telephone call service set is available in the current environment.

**Declared In**      TelephonyMgr.h

**Prototype**        TelIsSpCServiceAvailable (iRefnum, iAppId,  
ioTransIdP)

**Parameters**

- > iRefnum            The telephony manager library reference number.
- > iAppId             The telephone application attachment identifier for your application.
- <-> ioTransIdP        Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**    Returns errNone if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone if the service set is available, or an error code if not.
transId	The transaction ID of the operation.
paramP	kTelSpcServiceId
functionId	kTelUrqIsServiceAvailableMessage

**Comments** You need to call this macro before calling any function in the speech telephone call service set, which is the family of functions that begin with the TelSpc prefix.

The speech telephone call service set functions are documented in [Chapter 71, "Telephony Calls."](#)

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## **TellsStyServiceAvailable**

**Purpose** A macro that determines if the security service set is available in the current environment.

**Declared In** TelephonyMgr.h

**Prototype** TelIsStyServiceAvailable (iRefnum, iAppId, ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.

## Telephony Basic Services

### Telephony Functions

---

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available, or an error code if not.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` if the service set is available, or an error code if not.

`transId`          The transaction ID of the operation.

`paramP`           `kTelStyServiceId`

`functionId`      `kTelUrqIsServiceAvailableMessage`

**Comments** You need to call this macro before calling any function in the security service set, which is the family of functions that begin with the `TelSty` prefix.

The security service set functions are documented in [Chapter 70](#), “[Telephony Network](#).”

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

## TelMatchPhoneDriver

<b>Purpose</b>	Determines if the currently selected driver matches the connected phone.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelMatchPhoneDriver(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>A NULL pointer.</td></tr><tr><td>functionId</td><td>kTelUrqMatchPhoneDriverMessage</td></tr></table>	returnCode	errNone upon success or an error code upon failure	transId	The transaction ID of the operation.	paramP	A NULL pointer.	functionId	kTelUrqMatchPhoneDriverMessage
returnCode	errNone upon success or an error code upon failure								
transId	The transaction ID of the operation.								
paramP	A NULL pointer.								
functionId	kTelUrqMatchPhoneDriverMessage								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								

## TelOemCall

**Purpose** Pass a call to an OEM function.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelOemCall(UInt16 iRefnum, TelAppID iAppId, TelOemCallType *ioParamP, UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioParamP` A pointer to a [TelOemCallType](#) structure that contains information about the OEM function call.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transID` matches the output value of the `ioTransIdP` parameter

functionId	matches the function ID in the <a href="#">TelOemCallType</a> structure passed to this function in the ioParamP parameter
paramId	points to the <a href="#">TelOemCallType</a> structure passed to this function in the ioParamP parameter

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** Call this function to send a request to an OEM function. The calling function and the OEM function are responsible for coordinating the parameter block that is passed in the [TelOemCallType](#) structure. Before using this function, you should verify that it is available by calling the [TelIsOemServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelOpen

**Purpose** Open the telephony manager API to initialize telephony services and launch the telephony task.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelOpen(UINT16 iRefnum, UINT32 iVersnum, TelAppID *oAppIdP)`

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iVersnum	The version number of the shared library for which your application was developed.

## Telephony Basic Services

### Telephony Functions

---

`<- oAppIdP` A pointer to an application ID value. Upon return, this is the application ID that you supply as a parameter to the any other telephony functions that you call.

**Result** Returns `errNone` if the function was successful or returns an error code if not successful. The following errors can occur:

- the telephony task could not be found (`telErrTTaskNotFound`)
- the telephony task could not be launched (`telErrTTaskNotRunning`)
- the phone driver could not be found
- the shared library version is not valid

**Comments** You can only call this function synchronously. You must call this function before calling any other telephony manager functions. You can specify the current version of the shared library by using the `kTelMgrVersion` constant as the value of the `iVersnum` parameter.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelClose](#)

## TelOpenPhoneConnection

**Purpose** Open communications with the connected phone.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelOpenPhoneConnection(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**

- `-> iRefnum` The telephony manager library reference number.
- `-> iAppId` The telephone application attachment identifier for your application.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`          A `NULL` pointer.

`functionId`      `kTelUrqOpenPhoneConnectionMessage`

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelClosePhoneConnection](#)

## TelPowGetBatteryStatus

**Purpose** Retrieves the status of the phone's battery.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelPowGetBatteryStatus(UInt16 iRefnum,  
TelAppID iAppId, UInt8 *oStatusP,  
UInt16 *ioTransIdP)`

**Parameters**

- `-> iRefnum`      The telephony manager library reference number.
- `-> iAppId`        The telephone application attachment identifier for your application.

## Telephony Basic Services

### Telephony Functions

---

`<- oStatusP` A pointer to an unsigned byte value. Upon return, this is the battery status value, which is one of the [Battery Status Constants](#).

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously. If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` Points to the unsigned integer value passed to this function in the `oStatusP` parameter.

`functionId` `kTelPowBatteryStatusMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oStatusP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsPowServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPowGetPowerLevel](#)

## TelPowGetPowerLevel

<b>Purpose</b>	Retrieve the current level of the phone battery, as a percentage value.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelPowGetPowerLevel(UInt16 iRefnum, TelAppID iAppId, UInt8 *oPowerP, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;- oPowerP</td><td>A pointer to an unsigned byte value. Upon return, this is the battery percentage value.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<- oPowerP	A pointer to an unsigned byte value. Upon return, this is the battery percentage value.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<- oPowerP	A pointer to an unsigned byte value. Upon return, this is the battery percentage value.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>Points to the unsigned integer value passed to this function in the <code>oPowerP</code> parameter.</td></tr><tr><td>functionId</td><td><code>kTelPowGetPowerLevelMessage</code></td></tr></table>	returnCode	<code>errNone</code> upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	Points to the unsigned integer value passed to this function in the <code>oPowerP</code> parameter.	functionId	<code>kTelPowGetPowerLevelMessage</code>
returnCode	<code>errNone</code> upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	Points to the unsigned integer value passed to this function in the <code>oPowerP</code> parameter.								
functionId	<code>kTelPowGetPowerLevelMessage</code>								

## Telephony Basic Services

### Telephony Functions

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oPowerP` remains in memory until the asynchronous call completes.

---

**Comments** The returned percentage value is an integer value between 0 and 100.

Before using this function, you should verify that it is available by calling the [TelIsPowServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPowGetBatteryStatus](#)

## TelPowSetPhonePower

**Purpose** Turns the phone on or off.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelPowSetPhonePower(UInt16 iRefnum, TelAppID iAppId, Boolean iPowerOn)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iPowerOn` Set to `true` to turn the phone on, and set to `false` to turn the phone off.

**Result** Returns `errNone` if the function was successful and an error code if not.

**Comments** This function can only be called synchronously.

Before using this function, you should verify that it is available by calling the [TelIsPowServiceAvailable](#) macro.

This function corresponds to the `kTelPowSetPhonePowerMessage` function ID value.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelSendCommandString

**Purpose** Sends a command string to the phone or to the network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSendCommandString(UInt16 iRefnum,  
TelAppID iAppId,  
TelSendCommandStringType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioParamP` A pointer to a command string structure of type [TelSendCommandStringType](#).
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

## Telephony Basic Services

### Telephony Functions

---

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the <a href="#">TelSendCommandStringType</a> structure passed to this function in the ioParam parameter.
functionId	Matches the function ID in the <a href="#">TelOemCallType</a> referenced by the ioParamP structure.

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelSndMute

**Purpose** Mute or un-mute an active telephone call.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSndMute(UInt16 iRefnum, TelAppID iAppId, Boolean iMuteOn, UInt16 \*ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
-> iMuteOn	Set to true to mute the telephone call, or set to false to unmute the telephone call.
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the Boolean value passed to this function in the `iMuteOn` parameter.

`functionId`      `kTelSndMuteMessage`

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSndServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSndPlayKeyTone](#)

## **TelSndPlayKeyTone**

**Purpose** Play a keytone sound on the phone.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSndPlayKeyTone(UInt16 iRefnum,  
TelAppID iAppId, TelSndPlayKeyToneType *iParamP,  
UInt16 *ioTransIdP)`

**Parameters** `-> iRefnum`      The telephony manager library reference number.

## Telephony Basic Services

### Telephony Functions

---

- > `iAppId` The telephone application attachment identifier for your application.
- > `iParamP` A pointer to a [TelSndPlayKeyToneType](#) structure that describes the tone to play.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode` `errNone` upon success or an error code upon failure.
- `transId` The transaction ID of the operation.
- `paramP` Points to the [TelSndPlayKeyToneType](#) structure passed to this function in the `iKeyToneP` parameter.
- `functionId` `kTelSndPlayKeyTone`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSndServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSndStopKeyTone](#)

## TelSndStopKeyTone

<b>Purpose</b>	Stop the playing of a keytone sound on the phone.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelSndStopKeyTone(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>A NULL pointer.</td></tr><tr><td>functionId</td><td>kTelSndStopKeyToneMessage</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	A NULL pointer.	functionId	kTelSndStopKeyToneMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	A NULL pointer.								
functionId	kTelSndStopKeyToneMessage								
<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsSndServiceAvailable</a> macro.								

## Telephony Basic Services

### Feature Support Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSndPlayKeyTone](#)

## Feature Support Functions

This section describes the functions that you can call to determine if a specific feature or function is supported in the current operating environment.

### Tells<FunctionName>Supported

**Purpose** Determines if the specified function is supported.

**Declared In** `TelephonyMgr.h`

**Prototype** `TelIs<FunctionName>Supported (iRefnum, iAppId, ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the specified function is supported.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone if the specified function is supported, or an error code if not.
transId	The transaction ID of the operation.
paramP	The function ID of the function for which you are testing. For example, if you call <code>TelIsCgfGetSmsCenterSupported</code> , the value of this field is <code>kTelCgfGetSmsCenterMessage</code> .  The function ID value for each function is described in the documentation for the function.
functionId	<code>kTelUrqIsFunctionSupportedMessage</code>

**Comments** This is a family of synchronous macros that test if a specific function is available in the current environment.

To use the macro, substitute a function name for the `<FunctionName>` portion of the macro name. You can substitute any Telephony Manager function name; for a complete list of the Telephony Manager functions, see “[Summary of Telephony Manager](#)” on page 235 in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

For example, to determine if the [TelNwkGetSignalLevel](#) function is available in the current environment, call the `TelIsNwkGetSignalLevelSupported` macro.

---

**NOTE:** A service set can be available without all of its functions being available. Thus, if the [TelIs<ServiceSet>Available](#) macro returns `true` for a specific service set, you know that the service set is available, but you need to call [TelIs<FunctionName>Supported](#) to determine if a specific function is available.

---

This macro corresponds to the `kTelUrqIsFunctionSupportedMessage` function ID value.

## Telephony Basic Services

### Feature Support Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<ServiceSet>Available](#)

## Tells<ServiceSet>Available

**Purpose** Determines if the specified service set is available.

**Declared In** `TelephonyMgr.h`

**Prototype** `TelIs<ServiceSet>Available (iRefnum, iAppId, ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the service set is available.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` if the service set is available, or an error code if not.

`transId` The transaction ID of the operation.

paramP            The service ID of the service set for which you are testing. For example, if you call `TelIsCfgServiceAvailable`, the value of this field is `kTelCfgServiceId`.

The service IDs are described in [Service Set Constants](#).

functionId        `kTelUrqIsServiceAvailableMessage`

**Comments**      This is a family of synchronous macros that test if a specific service set is available. You must call the appropriate set availability function before calling a function in the set.

---

**NOTE:** A service set can be available without all of its functions being available. You can use this macro to determine the availability of a specific service set, which you might use to determine the configuration of your applications' user interface. To test if a specific function is supported, use the [TelIs<FunctionName>Supported](#) macro.

---

You can call these specific macros to determine if the service set is available:

- [TelIsCfgServiceAvailable](#) to determine if the configuration service set is available.
- [TelIsDtcServiceAvailable](#) to determine if the data calls service set is available.
- [TelIsEmcServiceAvailable](#) to determine if the emergency calls service set is available.
- [TelIsInfServiceAvailable](#) to determine if the information service set is available.
- [TelIsNwkServiceAvailable](#) to determine if the network service set is available.
- [TelIsOemServiceAvailable](#) to determine if the OEM service set is available.
- [TelIsPhbServiceAvailable](#) to determine if the phone book service set is available.

## Telephony Basic Services

### Feature Support Functions

---

- [TelIsPowServiceAvailable](#) to determine if the power service set is available.
- [TelIsSmsServiceAvailable](#) to determine if the SMS service set is available.
- [TelIsSndServiceAvailable](#) to determine if the sound service set is available.
- [TelIsSpcServiceAvailable](#) to determine if the speech calls service set is available.
- [TelIsStyServiceAvailable](#) to determine if the security service set is available.

Each of these macros corresponds to the `kTelUrqIsServiceSupportedMessage` function ID value.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelIs<FunctionName>Supported](#)

# Telephony Security and Configuration

---

This chapter describes the telephony security and configuration service sets of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Security and Configuration Data Structures](#)
- [Telephony Security and Configuration Constants](#)
- [Telephony Security and Configuration Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Security and Configuration Data Structures

This section describes the data structures used with the telephony security and configuration service sets portion of the telephony API.

### TelCfgGetPhoneNumberType

The [TelCfgGetPhoneNumber](#) function uses a `TelCfgGetPhoneNumberType` structure to retrieve the connected phone dial number.

## Telephony Security and Configuration

### Telephony Security and Configuration Data Structures

---

```
typedef struct _TelCfgGetPhoneNumberType
    UInt8    size;
    Char*    value;
} TelCfgGetPhoneNumberType
```

#### Field Descriptions

<-> size	The size of the value buffer.  When the structure is used as an input parameter, this is the allocated size, in bytes, of the value buffer.  Upon return, this is the actual size of the string, including the null terminator character. If the value buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.
<- value	A buffer into which the dial number is stored.  Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.

#### TelCfgGetSmsCenterType

The [TelCfgGetSmsCenter](#) function uses a `TelCfgGetSmsCenterType` structure to retrieve the SMS service center dial number.

```
typedef struct _TelCfgGetSmsCenterType
    UInt8    size;
    Char*    value;
} TelCfgGetSmsCenterType
```

### Field Descriptions

- `<-> size`                      The size of the `value` buffer.
- When the structure is used as an input parameter, this is the allocated size, in bytes, of the `value` buffer.
- Upon return, this is the actual size of the string, including the null terminator character. If the `value` buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.
- `<- value`                      A buffer into which the dial number is stored.
- Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

## TelStyChangeAuthenticationType

You use the `TelStyChangeAuthenticationType` to change an authentication code with the [TelStyChangeAuthenticationCode](#) function.

```
typedef struct _TelStyChangeAuthenticationType
{
    UInt    codeId;
    Char*   oldCode;
    Char*   newCode;
} TelStyChangeAuthenticationType
```

### Field Descriptions

- `-> codeId`                      The ID of the authentication code to change.
- `-> oldCode`                      The previous value of the code.
- `-> newCode`                      The new value of the code.

## Telephony Security and Configuration Constants

This section describes the constants used with the telephony security and configuration service sets of the telephony API.

### Authentication State Constants

The authentication state constants describe the current authentication state of the mobile unit connection.

Constant	Value	Description
<code>kTelStyReady</code>	0	No additional security information is expected.
<code>kTelStyPin1CodeId</code>	1	The PIN1 code is expected.
<code>kTelStyPin2CodeId</code>	2	The PIN2 code is expected.
<code>kTelStyPuk1CodeId</code>	3	The PUK1 code is expected.
<code>kTelStyPuk2CodeId</code>	4	The PUK2 code is expected.
<code>kTelStyPhoneToSimCodeId</code>	5	The phone-to-SIM code is expected.
<code>kTelStyFirstOemCodeId</code>	6	An OEM code is expected.

The constant `kTelStyFirstOemCodeId` specifies the first OEM authentication code. You can specify additional OEM codes by incrementing this value. For example, to specify the third OEM authentication code, use the following:

```
kTelStyFirstOemCodeId+2
```

---

## Telephony Security and Configuration Functions

This section describes the data structures used with the telephony security and configuration service sets portion of the telephony API.

## TelCfgGetPhoneNumber

<b>Purpose</b>	Retrieve the connected telephone number.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelCfgGetPhoneNumber(UInt16 iRefnum, TelAppID iAppId, TelCfgGetPhoneNumberType* ioParamP, UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioParamP</td><td>A pointer to a <a href="#">TelCfgGetPhoneNumberType</a> structure that is filled in with the dial telephone number.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioParamP	A pointer to a <a href="#">TelCfgGetPhoneNumberType</a> structure that is filled in with the dial telephone number.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioParamP	A pointer to a <a href="#">TelCfgGetPhoneNumberType</a> structure that is filled in with the dial telephone number.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.				
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								

## Telephony Security and Configuration

### Telephony Security and Configuration Functions

---

paramP	Points to the <a href="#">TelCfgGetPhoneNumberType</a> structure passed to this function in the ioParamP parameter.
functionId	kTelCfgGetPhoneNumberMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** The connected dial telephone number is stored into the value field of the [TelCfgGetPhoneNumberType](#) structure referenced by ioParamP. If the value field buffer is too small to contain the complete telephone number, the string is truncated (and ends with the null terminator character) and this function returns the telErrBufferSize error. The size field of the structure is always updated to contain the actual size of the complete telephone number.

Before using this function, you should verify that it is available by calling the [TelIsCfgServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelCfgSetSmsCenter](#), [TelSmsSendMessage](#)

## TelCfgGetSmsCenter

<b>Purpose</b>	Retrieve the SMS service center dial telephone number.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelCfgGetSmsCenter(UInt16 iRefnum, TelAppID iAppId, TelCfgGetSmsCenterType* ioParamP, UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioParamP</td><td>A pointer to a <a href="#">TelCfgGetSmsCenterType</a> structure that is filled in with the dial telephone number.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioParamP	A pointer to a <a href="#">TelCfgGetSmsCenterType</a> structure that is filled in with the dial telephone number.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioParamP	A pointer to a <a href="#">TelCfgGetSmsCenterType</a> structure that is filled in with the dial telephone number.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.				
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								

## Telephony Security and Configuration

### Telephony Security and Configuration Functions

---

paramP	Points to the <a href="#">TelCfgGetSmsCenterType</a> structure passed to this function in the ioParamP parameter.
functionId	kTelCfgGetSmsCenterMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** The service center dial telephone number is stored into the value field of the [TelCfgGetSmsCenterType](#) structure referenced by ioParamP. If the value field buffer is too small to contain the complete telephone number, the string is truncated (and ends with the null terminator character) and this function returns the telErrBufferSize error. The size field of the structure is always updated to contain the actual size of the complete telephone number.

Before using this function, you should verify that it is available by calling the [TelIsCfgServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelCfgSetSmsCenter](#), [TelSmsSendMessage](#)

## TelCfgSetSmsCenter

**Purpose** Set the SMS service center dial telephone number.

**Declared In** TelephonyMgr.h

**Prototype** Err TelCfgSetSmsCenter(UInt16 iRefnum,  
TelAppID iAppId, const Char\* iDialNumberP,  
UInt16\* ioTransIdP)

**Parameters** -> iRefnum The telephony manager library reference number.

## Telephony Security and Configuration

### *Telephony Security and Configuration Functions*

---

- > `iAppId`      The telephone application attachment identifier for your application.
- > `iDialNumberP`      A pointer to the null-terminated dial telephone number string for the SMS service center.
- <-> `ioTransIdP`      Set the value of this parameter to NULL to cause the function to execute synchronously.
- If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**      Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**      The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode`      `errNone` upon success or an error code upon failure.
- `transId`      The transaction ID of the operation.
- `paramP`      Points to the string passed to this function in the `iDialNumberP` parameter.
- `functionId`      `kTelCfgSetSmsCenterMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `iDialNumberP` remains in memory until the asynchronous call completes.

---

**Comments**      Before using this function, you should verify that it is available by calling the [TelIsCfgServiceAvailable](#) macro.

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

**See Also**      [TelCfgGetSmsCenter](#), [TelSmsSendMessage](#)

## Telephony Security and Configuration

### Telephony Security and Configuration Functions

---

## TelStyChangeAuthenticationCode

**Purpose** Change the value of an authentication code. Note that you can only use this function with GSM networks.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelStyChangeAuthenticationCode (UInt16 iRefnum, TelAppID iAppId, TelStyChangeAuthenticationType* iParamP, UInt16* ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iParamP` A pointer to a [TelStyChangeAuthenticationType](#) structure that contains the old and new authentication code values.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

## Telephony Security and Configuration

### Telephony Security and Configuration Functions

---

`paramP` Points to the [TelStyChangeAuthenticationType](#) structure passed to this function in the `iParamP` parameter.

`functionId` `kTelStyChangeAuthenticationCodeMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsStyServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelStyEnterAuthenticationCode](#)

## TelStyEnterAuthenticationCode

**Purpose** Enter the authentication code for which the phone is currently waiting. Note that you can only use this function with GSM networks.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelStyEnterAuthenticationCode(UInt16 iRefnum, TelAppID iAppId, const Char* iCodeP, UInt16* ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iCodeP` A pointer to the null-terminated authentication code string to send to the phone.

## Telephony Security and Configuration

### Telephony Security and Configuration Functions

---

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### Synchronous Result

Returns `errNone` if the function was successful or returns an error code if not successful.

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` Points to the string passed to this function in the `iCodeP` parameter.

`functionId` `kTelStyEnterAuthenticationCodeMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the string referenced by `iCodeP` remains in memory until the asynchronous call completes.

---

#### Comments

Before using this function, you should verify that it is available by calling the [TelIsStyServiceAvailable](#) macro.

#### Compatibility

Implemented only if [4.0 New Feature Set](#) is present.

#### See Also

[TelStyChangeAuthenticationCode](#),  
[TelStyGetAuthenticationState](#)

## TelStyGetAuthenticationState

<b>Purpose</b>	Returns the current state of user authentication.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelStyGetAuthenticationState(UInt16 iRefnum, TelAppID iAppId, UInt8* oStateP, UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;- oStateP</td><td>A pointer to an unsigned byte value. Upon return, this is the authentication state, which is one of the <a href="#">Authentication State Constants</a>.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<- oStateP	A pointer to an unsigned byte value. Upon return, this is the authentication state, which is one of the <a href="#">Authentication State Constants</a> .	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<- oStateP	A pointer to an unsigned byte value. Upon return, this is the authentication state, which is one of the <a href="#">Authentication State Constants</a> .								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>Points to the unsigned integer value passed to this function in the <code>oStateP</code> parameter.</td></tr><tr><td>functionId</td><td><code>kTelStyGetAuthenticationStateMessage</code></td></tr></table>	returnCode	<code>errNone</code> upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	Points to the unsigned integer value passed to this function in the <code>oStateP</code> parameter.	functionId	<code>kTelStyGetAuthenticationStateMessage</code>
returnCode	<code>errNone</code> upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	Points to the unsigned integer value passed to this function in the <code>oStateP</code> parameter.								
functionId	<code>kTelStyGetAuthenticationStateMessage</code>								

## Telephony Security and Configuration

### *Telephony Security and Configuration Functions*

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oStateP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsStyServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelStyEnterAuthenticationCode](#)

# Telephony Network

---

This chapter describes the telephony network service set of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Network Data Structures](#)
- [Telephony Network Constants](#)
- [Telephony Network Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Network Data Structures

This section describes the data structures used with the telephony network service set portion of the telephony API.

### TelNwkGetLocationType

You use the `TelNwkGetLocationType` structure with the [TelNwkGetLocation](#) function to retrieve information about the location of the phone.

```
typedef struct _TelNwkGetLocationType
{
    Char*    value;
    UInt16  size;
} TelNwkGetLocationType
```

## Telephony Network

### Telephony Network Data Structures

---

#### Field Descriptions

<-	value	<p>A buffer into which the current location string is stored. The format of this string is network-dependent.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<->	size	<p>The size of the <code>value</code> string. When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>value</code> buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the <code>value</code> buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>

#### TelNwkGetNetworkNameType

You use the `TelNwkGetNetworkNameType` structure with the [TelNwkGetNetworkName](#) function to retrieve the name of the specified, registered network.

```
typedef struct _TelNwkGetNetworkNameType
{
    UInt32    id;
    Char*     value;
    UInt16    size;
} TelNwkGetNetworkNameType
```

### Field Descriptions

-> id	The network ID.
<- value	A null-terminated string buffer into which the network name is stored.  Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.
<-> size	The size of the <code>value</code> string. When the structure is used as an input parameter, this is the allocated length, in bytes, of the <code>value</code> buffer.  Upon return, this is the actual size of the string, including the null terminator character. If the <code>value</code> buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.

### TelNwkGetNetworksType

You use the `TelNwkGetNetworksType` structure with the [TelNwkGetNetworks](#) function to retrieve the number of registered networks.

```
typedef struct _TelNwkGetNetworksType
{
    UInt32*  networkIdP;
    UInt8    size;
} TelNwkGetNetworksType
```

## Telephony Network

### Telephony Network Constants

---

#### Field Descriptions

`<- networkIdP` An array into which the retrieved network IDs are stored.

Note that if this buffer is too small to contain all of the available IDs, the data is truncated and the function using this structure generates a `telErrBufferSize` error.

`<-> size` When the structure is use as an input value, this is the allocated size, in elements, of the `networkIdP` array.

When the structure is used as a return value, this is the number of network IDs that are available. If the the `networkP` buffer is too small to contain all of the retrieved IDs, this field is assigned the entire number of available IDs, and the function using this structure generates a `telErrBufferSize` error

## Telephony Network Constants

This section describes the constants used with the telephony network service set of the telephony API, which include the following constant types:

- [Network Type Constants](#)
- [Network Search Mode Constants](#)

### Network Type Constants

The network type constants describe the type of network connection.

---

Constant	Value	Description
<code>kTelNwkCDMA</code>	0	A CDMA network.
<code>kTelNwkGSM</code>	1	A GSM network.

---

Constant	Value	Description
kTelNwkTDMA	2	A TDMA network.
kTelNwkPDC	3	A PDC network.

## Network Search Mode Constants

The network search mode constants describe the search mode used to find a network.

Constant	Value	Description
kTelNwkManualSearch	0	Manual network searching.
kTelNwkAutomaticSearch	1	Automatic network searching.

## Telephony Network Functions

This section describes the data structures used with the telephony network service set portion of the telephony API.

### TelNwkGetLocation

<b>Purpose</b>	Retrieve information about the location of the mobile unit.						
<b>Declared In</b>	TelephonyMgr.h						
<b>Prototype</b>	Err TelNwkGetLocation(UInt16 iRefnum, TelAppID iAppId, TelNwkGetLocationType* ioParamP, UInt16* ioTransIdP)						
<b>Parameters</b>	<table style="width: 100%; border: none;"> <tr> <td style="padding-right: 10px;">-&gt; iRefnum</td> <td>The telephony manager library reference number.</td> </tr> <tr> <td style="padding-right: 10px;">-&gt; iAppId</td> <td>The telephone application attachment identifier for your application.</td> </tr> <tr> <td style="padding-right: 10px;">&lt;-&gt; ioParamP</td> <td>A pointer to a <a href="#">TelNwkGetLocationType</a> structure.</td> </tr> </table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioParamP	A pointer to a <a href="#">TelNwkGetLocationType</a> structure.
-> iRefnum	The telephony manager library reference number.						
-> iAppId	The telephone application attachment identifier for your application.						
<-> ioParamP	A pointer to a <a href="#">TelNwkGetLocationType</a> structure.						

## Telephony Network

### Telephony Network Functions

---

On input, the `size` field of this structure specifies the allocated size of the `value` buffer. Upon return, the `size` field specifies the actual size of the location string, even if it was truncated to fit into the buffer.

<-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` Points to the [TelNwkGetLocationType](#) passed to this function in the `ioParamP` parameter.

`functionId` `kTelNwkGetLocationMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments** The location information string is stored into the `value` field of the [TelNwkGetLocationType](#) structure referenced by `ioParamP`. If the `value` buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete string.

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelNwkGetNetworkName

**Purpose** Returns the name of a registered network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelNwkGetNetworkName (UInt16 iRefnum,  
TelAppID iAppId,  
TelNwkGetNetworkNameType* ioParamP,  
UInt16* ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioParamP` A pointer to a [TelNwkGetNetworkNameType](#) structure that stores the network name.  
On input, the `size` field of this structure specifies the allocated size of the `value` buffer. Upon return, the `size` field specifies the actual size of the name string, even if it was truncated to fit into the buffer.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

## Telephony Network

### Telephony Network Functions

---

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelNwkGetNetworkNameType</a> passed to this function in the <code>ioParamP</code> parameter.
<code>functionId</code>	<code>kTelNwkGetNetworkNameMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### Comments

The network name string is stored into the `value` field of the structure. If the `value` field buffer in the [TelNwkGetNetworkNameType](#) structure is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field is always updated to contain the actual size of the complete string.

The string that is returned in the `value` field of the structure referenced by `ioParamP` is network dependent.

On a GSM network, the result string is compliant with the AT 07.07 European Telecommunications Standards Institute (ETSI) standard for COPS and CREG commands. The result string contains the following elements:

- The network type, as returned by the [TelNwkGetNetworkType](#) function, and followed by a semicolon ( `' ; '` ) character.
- The network operator, using the following syntax:

`<area code> ';' <network registration>`

The `<area code>` value is the value retrieved by issuing the `AT+CREG?` command.

The `<network registration>` value is the value retrieved by issuing the `AT+CREG?` command.

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelNwkGetNetworks](#), [TelNwkGetSelectedNetwork](#)

## TelNwkGetNetworks

**Purpose**          Retrieves information about the registered networks.

**Declared In**    `TelephonyMgr.h`

**Prototype**      `Err TelNwkGetNetworks(UInt16 iRefnum,  
TelAppID iAppId, TelNwkGetNetworksType* ioParamP,  
UInt16* ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;-&gt; ioParamP</code>	A pointer to a <a href="#">TelNwkGetNetworksType</a> structure that stores the network IDs. On input, the <code>size</code> field of this structure contains the size, in elements, of the <code>networkIdP</code> array field.  Upon return, the <code>networkIdP</code> array contains the IDs of the registered networks, and the <code>size</code> field contains the number of IDs in the array.

## Telephony Network

### Telephony Network Functions

---

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### Synchronous Result

Returns `errNone` if the function was successful or returns an error code if not successful.

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` Points to the [TelNwkGetNetworksType](#) passed to this function in the `ioParamP` parameter.

`functionId` `kTelNwkGetNetworkCountMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

#### Comments

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

#### Compatibility

Implemented only if [4.0 New Feature Set](#) is present.

#### See Also

functionId	<code>kTelNwkGetNetworkTypeMessage</code>								

## Telephony Network

### Telephony Network Functions

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value you pass for the `oTypeP` parameter remains in memory until the asynchronous call completes.

---

- Comments** Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelNwkGetSearchMode

- Purpose** Returns the current network search mode.
- Declared In** `TelephonyMgr.h`
- Prototype**  
`Err TelNwkGetSearchMode(UInt16 iRefnum,  
TelAppID iAppId, UInt8* oModeP,  
UInt16* ioTransIdP)`
- Parameters**
- > `iRefnum` The telephony manager library reference number.
  - > `iAppId` The telephone application attachment identifier for your application.
  - <- `oModeP` A pointer to an unsigned byte value. Upon return, this is the type of search mode that is currently being used. This is one of the [Network Search Mode Constants](#).
  - <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the unsigned integer value passed to this function in the `oModeP` parameter.

`functionId`      `kTelNwkGetSearchModeMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oModeP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelNwkSetSearchMode](#)

## TeINwkGetSelectedNetwork

**Purpose** Retrieve the network identifier of the currently selected network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelNwkGetSelectedNetwork(UInt16 iRefnum, TelAppID iAppId, UInt32* oNetworkIdP, UInt16* ioTransIdP)`

**Parameters** `-> iRefnum`      The telephony manager library reference number.

## Telephony Network

### Telephony Network Functions

---

- > `iAppId` The telephone application attachment identifier for your application.
- <- `oNetworkIdP` A pointer to an unsigned integer value. Upon return, this is the identifier of the currently selected network.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.
- If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### Synchronous Result

Returns `errNone` if the function was successful or returns an error code if not successful.

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode` `errNone` upon success or an error code upon failure.
- `transId` The transaction ID of the operation.
- `paramP` Points to the unsigned integer value passed to this function in the `oNetworkIdP` parameter.
- `functionId` `kTelNwkGetSelectedNetworkMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oNetworkP` remains in memory until the asynchronous call completes.

---

#### Comments

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelNwkGetNetworkName](#), [TelNwkGetNetworks](#),  
[TelNwkSelectNetwork](#)

## **TelNwkGetSignalLevel**

**Purpose**            Retrieve the selected network carrier signal level.

**Declared In**     `TelephonyMgr.h`

**Prototype**       `Err TelNwkGetSignalLevel(UInt16 iRefnum,  
TelAppID iAppId, UInt8* oSignalP,  
UInt16* ioTransIdP)`

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
<- oSignalP	A pointer to an unsigned byte value. Upon return, this is an indication of the signal level in decibels per milliwatt (dBm). The values are explained in the Comments section.
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**    Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**    The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

## Telephony Network

### Telephony Network Functions

---

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the oSignalP parameter.
functionId	kTelNwkGetSignalLevelMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oSignalP remains in memory until the asynchronous call completes.

---

**Comments** This function sets the value of the variable referenced by oSignalP to an integer value that indicates the signal strength in dBm. The following table describes the signal strength values.

---

Signal level value	dBm value
0	≤ 113 dBm
1	111 dBm
2 to 30	109 dBm to 53 dBm
31	≥ 51 dBm
99	unknown or undetectable

---

Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelNwkSelectNetwork

<b>Purpose</b>	Select a network to use from among the set of registered networks.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelNwkSelectNetwork(UInt16 iRefnum, TelAppID iAppId, UInt32 iNetworkId, UInt16* ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>-&gt; iNetworkId</td><td>The identifier of the network to select.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	-> iNetworkId	The identifier of the network to select.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
-> iNetworkId	The identifier of the network to select.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>Points to the network unsigned integer value passed to this function in the <code>iNetworkId</code> parameter.</td></tr><tr><td>functionId</td><td>kTelNwkSelectNetworkMessage</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	Points to the network unsigned integer value passed to this function in the <code>iNetworkId</code> parameter.	functionId	kTelNwkSelectNetworkMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	Points to the network unsigned integer value passed to this function in the <code>iNetworkId</code> parameter.								
functionId	kTelNwkSelectNetworkMessage								

## Telephony Network

### Telephony Network Functions

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelNwkGetNetworkName](#), [TelNwkGetNetworks](#),  
[TelNwkGetSelectedNetwork](#)

## TelNwkSetSearchMode

**Purpose** Sets the search mode used to find a network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelNwkSetSearchMode(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iMode, UInt16* ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iMode` The search mode to use. This must be one of the [Network Search Mode Constants](#).
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the iMode parameter.
functionId	kTelNwkSetSearchModeMessage

**Comments** Before using this function, you should verify that it is available by calling the [TelIsNwkServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelNwkGetSearchMode](#)

# Telephony Calls

---

This chapter describes the telephony calls service sets of the telephony API, which include:

- The data calls service set
- The emergency calls service set
- The speech (voice) calls service set

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Calls Data Structures](#)
- [Telephony Calls Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Calls Data Structures

This section describes the data structures used with the telephony calls service sets portion of the telephony manager API.

### TelDtcCallNumberType

The [TelDtcCallNumber](#) function uses the `TelDataCallNumberType` structure to specify information about the telephone number to call.

```
typedef struct _TelDtcCallNumberType
{
    char    *dialNumberP;
    UInt8   lineId;
} TelDtcCallNumberType
```

## Telephony Calls

### Telephony Calls Data Structures

---

#### Field Descriptions

- > dialNumberP            The telephone number to dial.
- <- lineId                Upon return from the [TelDtcCallNumber](#) function, this is the ID of the data line that was established for the telephone call.

#### TelDtcReceiveDataType

The [TelDtcReceiveData](#) function uses a `TelDtcReceiveDataType` structure to receive data from an open data line.

```
typedef struct _TelDtcReceiveDataType
{
    UInt8      *data;
    UInt32     size;
    UInt32     timeout;
} TelDtcReceiveDataType
```

#### Field Descriptions

- <- data                A buffer into which the data is stored.
- Note that if this buffer is too small to contain all of the available data, the end of the data is truncated and the function using this structure generates a `telErrBufferSize` error.
- <-> size              When the structure is used as an input parameter, this is the allocated size, in bytes, of the data buffer.
- Upon return, this is the actual number of bytes of data that was retrieved. If the data buffer is too small to contain all of the retrieved data, the function using this structure generates a `telErrBufferSize` error.
- > timeout             The number of milliseconds to wait before timing out.

## TelDtcSendDataType

The [TelDtcReceiveData](#) function uses a `TelDtcSendDataType` structure to send data to an open data line.

```
typedef struct _TelDtcSendDataType
{
    UInt8      *data;
    UInt32     size;
} TelDtcSendDataType
```

### Field Descriptions

- > `data`                      A pointer to the data to send.
- > `size`                        The number of bytes of data in the data buffer.

## TeleMcGetNumberType

The [TeleMcGetNumber](#) function uses a `TeleMcGetNumberType` structure to retrieve an emergency dial telephone number.

```
typedef struct _TeleMcGetNumberType
{
    UInt8      index;
    UInt8      size;
    Char       *value;
} TeleMcGetNumberType
```

### Field Descriptions

- > `index`                      The index of the telephone number. This is a zero-based index.

## Telephony Calls

### Telephony Calls Data Structures

---

<code>&lt;-&gt;</code> <code>size</code>	<p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>value</code> buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the <code>value</code> buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>&lt;-</code> <code>value</code>	<p>A null-terminated string buffer into which the emergency dial telephone number is stored.</p> <p>Note that if this buffer is too small to contain all of the available data, the end of the data is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.</p>

## TelemcSetNumberType

The [TelEmcSetNumber](#) function uses a `TelemcNumberType` structure to set an emergency dial telephone number.

```
typedef struct _TelemcSetNumberType
{
    UInt8  index;
    Char   *value;
} TelemcSetNumberType
```

### Field Descriptions

<code>-&gt;</code> <code>index</code>	The index of the telephone number. This is a zero-based index.
<code>-&gt;</code> <code>value</code>	The string value of the number to store as the <code>index</code> th entry.

## TelSpcGetCallerNumberType

The [TelSpcGetCallerNumber](#) function uses a `TelSpcGetCallerNumberType` structure to retrieve an incoming telephone number.

```
typedef struct _TelSpcGetCallerNumberType
{
    Char    *value;
    UInt8   size;
} TelSpcGetCallerNumberType
```

### Field Descriptions

- `<- value`                      A null-terminated string buffer into which the caller telephone number is stored.
- Note that if this buffer is too small to contain all of the available data, the end of the data is truncated and the function using this structure generates a `telErrBufferSize` error.
- `<-> size`                      When the structure is used as an input parameter, this is the allocated size, in bytes, of the `value` buffer.
- Upon return, this is the actual size of the caller dial telephone number, including the null terminator character. If the `value` buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

### TelSpcPlayDTMFType

The [TelSpcPlayDTMF](#) function uses a `TelSpcPlayDTMFType` structure to specify the qualities of the DTMF (dual-tone, multi-frequency) sound sent by the phone to the network or remote, connected equipment.

```
typedef struct _TelSpcPlayDTMFType
    UInt8   keyTone;
    UInt32  duration;
} TelSpcPlayDTMFType
```

## Telephony Calls

### Telephony Calls Functions

---

#### Field Descriptions

- > `keyTone`                    The keycode of the key tone to play. This must be one of the [Keycode Constants](#).
- > `duration`                    The duration of the tone, specified as a multiple of ten milliseconds.

## Telephony Calls Functions

This section describes the functions used with the telephony calls service sets portion of the telephony API.

### TelDtcCallNumber

**Purpose**                    Initiate a data telephone call.

**Declared In**              `TelephonyMgr.h`

**Prototype**                `Err TelDtcCallNumber (UInt16 iRefnum,  
TelAppID iAppId, TelDtcCallNumberType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum`                    The telephony manager library reference number.
- > `iAppId`                    The telephone application attachment identifier for your application.
- <-> `ioParamP`                A pointer to a [TelDtcCallNumberType](#) structure that specifies information about the telephone call.
- <-> `ioTransIdP`              Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelDtcCallNumberType](#) structure passed to this function in the `ioDataCallParamP` parameter.

`functionId`      `kTelDtcCallNumberMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioDataCallParamP` remains in memory until the asynchronous call completes.

---

**Comments** Call this function to start a data telephone call.

Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelDtcCloseLine](#)

## Telephony Calls

### Telephony Calls Functions

---

## TelDtcCloseLine

**Purpose** Hang up a data line.

**Declared In** TelephonyMgr.h

**Prototype** Err TelDtcCloseLine(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iLineId,  
UInt16 \*ioTransIdP)

**Parameters**

- > iRefnum The telephony manager library reference number.
- > iAppId The telephone application attachment identifier for your application.
- > iLineId The ID of the line to hang up. This is the ID returned by a previous call to the [TelDtcCallNumber](#) function.
- <-> ioTransIdP Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns errNone if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- returnCode errNone upon success or an error code upon failure.
- transId The transaction ID of the operation.
- paramP Points to the unsigned integer value passed to this function in the iLineId parameter.
- functionId kTelDtcCloseLineMessage

**Comments** Call this function to end a data telephone call.  
Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelDtcCallNumber](#)

## TelDtcReceiveData

**Purpose** Receive data on an opened data communications line.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelDtcReceiveData(UInt16 iRefnum,  
TelAppID iAppId, TelDtcReceiveDataType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioParamP` A pointer to a [TelDtcReceiveDataType](#) structure.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

## Telephony Calls

### Telephony Calls Functions

---

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the <a href="#">TelDtcReceiveDataType</a> structure passed to this function in the ioRcvDataP parameter.
functionId	kTelDtcReceiveDataMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** Call this function to receive data during an active data telephone call.

Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelDtcCallNumber](#), [TelDtcCloseLine](#), [TelDtcSendData](#)

## TelDtcSendData

**Purpose** Send data on an opened data line.

**Declared In** TelephonyMgr.h

**Prototype** Err TelDtcSendData(UInt16 iRefnum,  
TelAppID iAppId, TelDtcSendDataType \*iParamP,  
UInt16 \*ioTransIdP)

**Parameters** -> iRefnum The telephony manager library reference number.

- > `iAppId`      The telephone application attachment identifier for your application.
- > `iParamP`      A pointer to a [TelDtcSendDataType](#) structure that specifies the data to send.
- <-> `ioTransIdP`   Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**      Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**      The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode`      `errNone` upon success or an error code upon failure.
- `transId`          The transaction ID of the operation.
- `paramP`          Points to the [TelDtcSendDataType](#) structure passed to this function in the `iSendDataP` parameter.
- `functionId`      `kTelDtcSendMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments**      Call this function to send data during an active data telephone call. Before using this function, you should verify that it is available by calling the [TelIsDtcServiceAvailable](#) macro.

## Telephony Calls

### Telephony Calls Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelDtcCallNumber](#), [TelDtcCloseLine](#), [TelDtcReceiveData](#)

## TelEmcCall

**Purpose** Call the currently selected emergency service.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelEmcCall(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` A NULL pointer.

`functionId` `kTelEmcCallMessage`

**Comments** This function calls the telephone number specified in a previous call to the [TelEmcSelectNumber](#) function. In synchronous mode, this function returns after the dial command has been sent to the phone. After calling this function, sub-launched applications can receive notifications when the following telephony events occur. Note that these notifications can be raised after both synchronous and asynchronous calls to this function.

---

<b>Event</b>	<b>Description</b>
<code>sysTelSpcLaunchCmdCallReleased</code>	Warns that the telephone call has been released.
<code>sysTelSpcLaunchCmdCallBusy</code>	Warns that the called equipment is busy.
<code>sysTelSpcLaunchCmdCallConnect</code>	Warns that the line is open. The ID of the open line is stored in the <code>UInt32</code> value of the parameter block passed to the application.
<code>sysTelSpcLaunchCmdCallError</code>	Warns that an error occurred while attempting to complete the telephone call.

---

Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcCloseLine](#),

## Telephony Calls

### Telephony Calls Functions

---

## TelEmcCloseLine

<b>Purpose</b>	Close the line that is currently opened for an emergency telephone call.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelEmcCloseLine(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>A NULL pointer.</td></tr><tr><td>functionId</td><td><code>kTelDtcCloseLineMessage</code></td></tr></table>	returnCode	<code>errNone</code> upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	A NULL pointer.	functionId	<code>kTelDtcCloseLineMessage</code>
returnCode	<code>errNone</code> upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	A NULL pointer.								
functionId	<code>kTelDtcCloseLineMessage</code>								
<b>Comments</b>	Call this function to end an emergency telephone call.  Before using this function, you should verify that it is available by calling the <a href="#">TelIsEmcServiceAvailable</a> macro.								

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**        [TelEmcCall](#)

## TelEmcGetNumber

**Purpose**            Retrieve an emergency dial telephone number.

**Declared In**      `TelephonyMgr.h`

**Prototype**        `Err TelEmcGetNumber(UInt16 iRefnum,  
TelAppID iAppId, TelEmcGetNumberType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;-&gt; ioParamP</code>	A pointer to a <a href="#">TelEmcGetNumberType</a> structure in which you assign the index of the telephone number that you want to retrieve.  On input, the <code>size</code> field of this structure specifies the allocated size of the <code>value</code> buffer. Upon return, the <code>size</code> field specifies the actual size of the telephone number, even if it was truncated to fit into the buffer.
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.  If this parameter is not <code>NULL</code> , the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**    Returns `errNone` if the function was successful or returns an error code if not successful.

## Telephony Calls

### Telephony Calls Functions

---

<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:
<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelEmcGetNumberType</a> structure passed to this function in the <code>ioGetNumberP</code> parameter.
<code>functionId</code>	<code>kTelEmcGetNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments** The emergency call telephone number is stored into the `value` field of the [TelEmcGetNumberType](#) structure referenced by `ioGetNumberP`. If the `value` buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete string. Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcGetNumberCount](#), [TelEmcSetNumber](#), [TelEmcSelectNumber](#)

## TelEmcGetNumberCount

<b>Purpose</b>	Retrieve the count of emergency dial telephone numbers.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelEmcGetNumberCount (UInt16 iRefnum, TelAppID iAppId, UInt8 *oCountP, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;- oCountP</td><td>Upon return, the total number of emergency call numbers available.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<- oCountP	Upon return, the total number of emergency call numbers available.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<- oCountP	Upon return, the total number of emergency call numbers available.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>Points to unsigned integer passed to this function in the oCountP parameter.</td></tr><tr><td>functionId</td><td>kTelEmcGetNumberMessage</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	Points to unsigned integer passed to this function in the oCountP parameter.	functionId	kTelEmcGetNumberMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	Points to unsigned integer passed to this function in the oCountP parameter.								
functionId	kTelEmcGetNumberMessage								

## Telephony Calls

### Telephony Calls Functions

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oCountP` remains in memory until the asynchronous call completes.

---

**Comments** The emergency telephone call number is stored into the `value` field of the [TelEmcGetNumberType](#) structure referenced by `ioGetNumberP`. If the value buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete string. Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcGetNumber](#), [TelEmcSetNumber](#), [TelEmcSelectNumber](#)

## TelEmcSelectNumber

**Purpose** Select the current emergency telephone number. This is the telephone number that gets dialed when you call the [TelEmcCall](#) function.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelEmcSelectNumber(UInt16 iRefnum,
TelAppID iAppId, UInt8 iIndex,
UInt16 *ioTransIdP)
```

**Parameters**

-> <code>iRefnum</code>	The telephony manager library reference number.
-> <code>iAppId</code>	The telephone application attachment identifier for your application.
-> <code>iIndex</code>	The zero-based index of the emergency telephone number that you want selected.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`          Points to the unsigned integer value passed to this function in the `iIndex` parameter.

`functionId`      `kTelEmcSelectNumberMessage`

**Comments** Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcCall](#), [TelEmcGetNumber](#), [TelEmcGetNumberCount](#), [TelEmcSetNumber](#)

## Telephony Calls

### Telephony Calls Functions

---

## TelEmcSetNumber

**Purpose** Set the telephone number for the specified emergency dial number.

**Declared In** TelephonyMgr.h

**Prototype** `Err TelEmcSetNumber(UInt16 iRefnum, TelAppID iAppId, TelEmcSetNumberType *iParamP, UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iParamP` A pointer to a [TelEmcSetNumberType](#) structure that specifies the telephone number.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the <a href="#">TelEmcSetNumberType</a> structure passed to this function in the <code>iNumberP</code> parameter.
<code>functionId</code>	<code>kTelEmcSetNumberMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments** Call this function to associate a new telephone number with the emergency dial number that has the specified `iIndex`.  
Before using this function, you should verify that it is available by calling the [TelIsEmcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelEmcGetNumber](#),

## TelSpcAcceptCall

**Purpose** Accept an incoming voice telephone call.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcAcceptCall (UInt16 iRefnum,  
TelAppID iAppId, UInt8 *oLineIdP,  
UInt16 *ioTransIdP)`

**Parameters**

-> <code>iRefnum</code>	The telephony manager library reference number.
-> <code>iAppId</code>	The telephone application attachment identifier for your application.
<- <code>oLineIdP</code>	A pointer to an unsigned byte value. Upon return, this is the ID of the voice line assigned to the telephone call.
<-> <code>ioTransIdP</code>	Set the value of this parameter to NULL to cause the function to execute synchronously.

## Telephony Calls

### Telephony Calls Functions

---

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the unsigned integer passed to this function in the <code>oLineIdP</code> parameter.
<code>functionId</code>	<code>kTelSpcAcceptCallMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oLineIdP` remains in memory until the asynchronous call completes.

---

**Comments** If another line was active prior to the execution of this function, that line is put on hold. Note that there can only be one line active at any given time, and there can only be one line on hold at any given time. Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcGetCallerNumber](#), [TelSpcRejectCall](#)

## TelSpcCallNumber

<b>Purpose</b>	Initiate a voice telephone call.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelSpcCallNumber(UInt16 iRefnum, TelAppID iAppId, const Char *iDialNumberP, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>-&gt; iDialNumberP</td><td>A pointer to the telephone number to call.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	-> iDialNumberP	A pointer to the telephone number to call.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
-> iDialNumberP	A pointer to the telephone number to call.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td><code>errNone</code> upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>Points to the string passed to this function in the <code>iDialNumberP</code> parameter.</td></tr><tr><td>functionId</td><td><code>kTelSpcCallNumberMessage</code></td></tr></table>	returnCode	<code>errNone</code> upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	Points to the string passed to this function in the <code>iDialNumberP</code> parameter.	functionId	<code>kTelSpcCallNumberMessage</code>
returnCode	<code>errNone</code> upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	Points to the string passed to this function in the <code>iDialNumberP</code> parameter.								
functionId	<code>kTelSpcCallNumberMessage</code>								

## Telephony Calls

### Telephony Calls Functions

---

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `iDialNumberP` remains in memory until the asynchronous call completes.

---

#### Comments

A successful return from a synchronous call or receipt of a successful notification from an asynchronous call does not mean that the telephone call has been connected; instead, it indicates that the dial command was sent to the phone. Successful connection of the telephone call is indicated with a sub-launch.

The dial number is formatted according to the following syntax:

```
DialNumber ::= <Phone_Number> | <Code_String>
              | <Phone_Number> <Code_String>
```

```
Phone_Number ::= <IntlPrefix><NatlNumber>
                 | <NatlNumber>
```

```
IntlPrefix ::= '+' <country code>
```

```
NatlNumber ::= {{Pause<Pause>}}{<Digit>}}
```

```
Code_String ::= <Symbol>{<Symbol>}
```

```
Symbol ::= <Digit> | '#' | '*'
```

```
Digit ::= '0' | '1' | '2' | '3' | '4'
          | '5' | '6' | '7' | '8' | '9'
```

```
Pause ::= ','
```

After calling this function, sub-launched applications can receive notifications when the following telephony events occur. Note that these notifications can be raised after both synchronous and asynchronous calls to this function.

<b>Event</b>	<b>Description</b>
<code>sysTelSpcLaunchCmdCallReleased</code>	This is passed to a sub-launched application to warn that the telephone call has been released.
<code>sysTelSpcLaunchCmdCallBusy</code>	This is passed to a sub-launched application to warn that the called equipment is busy.
<code>sysTelSpcLaunchCmdCallConnect</code>	This is passed to a sub-launched application to warn that the line is open. The ID of the open line is stored in the <code>UInt32</code> value of the parameter block passed to the application.
<code>sysTelSpcLaunchCmdCallError</code>	This is passed to a sub-launched application to warn that the telephone call encountered an error.

---

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcCloseLine](#)

## **TelSpcCloseLine**

**Purpose** Ends a voice telephone call.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcCloseLine(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iLineId,  
UInt16 *ioTransIdP)`

**Parameters** `-> iRefnum` The telephony manager library reference number.

## Telephony Calls

### Telephony Calls Functions

---

- > `iAppId` The telephone application attachment identifier for your application.
- > `iLineId` The ID of the voice line that you want to close. This is the ID returned by a previous call to the [TelSpcAcceptCall](#) function.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode` `errNone` upon success or an error code upon failure.
- `transId` The transaction ID of the operation.
- `paramP` Points to the unsigned integer value passed to this function in the `iLineId` parameter.
- `functionId` `kTelSpcCloseLineMessage`

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSpServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcCallNumber](#)

## TelSpcConference

<b>Purpose</b>	Initiate a conference telephone call by merging the active line and the held line.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelSpcConference(UInt16 iRefnum, TelAppID iAppId, UInt8 *oLineIdP, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;- oLineIdP</td><td>A pointer to an unsigned byte value. Upon return, this is the ID of the voice line assigned to the telephone call.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<- oLineIdP	A pointer to an unsigned byte value. Upon return, this is the ID of the voice line assigned to the telephone call.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<- oLineIdP	A pointer to an unsigned byte value. Upon return, this is the ID of the voice line assigned to the telephone call.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.				
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								

## Telephony Calls

### Telephony Calls Functions

---

paramP	Points to the unsigned integer value passed to this function in the oLineIdP parameter.
functionId	kTelSpcConferenceMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oLineIdP remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcCallNumber](#), [TelSpcCloseLine](#), [TelSpcHoldLine](#), [TelSpcRetrieveHeldLine](#), [TelSpcSelectLine](#)

## TelSpcGetCallerNumber

**Purpose** Retrieve the telephone number of the caller on an incoming telephone call.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSpcGetCallerNumber (UInt16 iRefnum,  
TelAppID iAppId,  
TelSpcGetCallerNumberType \*ioParamP,  
UInt16 \*ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.

- `<-> ioParamP` A pointer to a [TelSpcGetCallerNumberType](#) structure that is used to retrieve the caller's telephone number.
- On input, the `size` field of this structure specifies the allocated size of the `value` buffer. Upon return, the `size` field specifies the actual size of the telephone number, even if it was truncated to fit into the buffer.
- `<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.
- If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful. If there is no active incoming telephone call, this function returns the `telErrUnavailableValue` error.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode` `errNone` upon success or an error code upon failure.
- `transId` The transaction ID of the operation.
- `paramP` Points to the [TelSpcGetCallerNumberType](#) structure passed to this function in the `ioParamP` parameter.
- `functionId` `kTelSpcGetCallerNumberMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

## Telephony Calls

### Telephony Calls Functions

---

**Comments** The emergency telephone call number is stored into the `value` field of the [TelSpcGetCallerNumberType](#) structure referenced by `ioParamP`. If the value buffer is too small to contain the complete string, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `size` field of the structure is always updated to contain the actual size of the complete string.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcAcceptCall](#)

## TelSpcHoldLine

**Purpose** Put the currently active voice line on hold.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcHoldLine(UInt16 iRefnum,  
TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	A NULL pointer.
functionId	kTelSpcHoldLineMessage

**Comments** Note that there can only be one line active at any given time, and there can only be one line on hold at any given time.  
Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcRetrieveHeldLine](#)

## TelSpcPlayDTMF

**Purpose** Play a dual-tone multi-frequency sound to the network system for a specified duration. Note that you can only play a DTMF while a voice telephone call is active.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcPlayDTMF(UInt16 iRefnum, TelAppID iAppId, TelSpcPlayDTMFType *iParamP, UInt16 *ioTransIdP)`

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.

## Telephony Calls

### Telephony Calls Functions

---

- > `iParamP` A pointer to a [TelSpcPlayDTMFType](#) structure that specifies the tone to play and its duration.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.
- If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- `returnCode` `errNone` upon success or an error code upon failure.
- `transId` The transaction ID of the operation.
- `paramP` Points to the [TelSpcPlayDTMFType](#) structure passed to this function in the `iParamP` parameter
- `functionId` `kTelSpcPlayDTMFMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iParamP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcSendBurstDTMF](#), [TelSpcStartContinuousDTMF](#), [TelSpcStopContinuousDTMF](#)

## TelSpcRejectCall

<b>Purpose</b>	Reject an incoming voice telephone call.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelSpcRejectCall(UInt16 iRefnum, TelAppID iAppId, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.		
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	<p>The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:</p> <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr><tr><td>paramP</td><td>A NULL pointer.</td></tr><tr><td>functionId</td><td>kTelSpcRejectCallMessage</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.	paramP	A NULL pointer.	functionId	kTelSpcRejectCallMessage
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								
paramP	A NULL pointer.								
functionId	kTelSpcRejectCallMessage								
<b>Comments</b>	Before using this function, you should verify that it is available by calling the <a href="#">TelIsSpcServiceAvailable</a> macro.								

## Telephony Calls

### Telephony Calls Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcAcceptCall](#), [TelSpcGetCallerNumber](#)

## TelSpcRetrieveHeldLine

**Purpose** Reconnect the voice line that is currently on hold, making it the active voice line.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcRetrieveHeldLine(UInt16 iRefnum,  
TelAppID iAppId, UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	A NULL pointer.
<code>functionId</code>	<code>kTelSpcRetrieveHeldLineMessage</code>

**Comments** Note that there can only be one line active at any given time, and there can only be one line on hold at any given time.  
Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcHoldLine](#)

## TelSpcSelectLine

**Purpose** Select the specified line ID as the newly active voice line.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcSelectLine(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iLineId,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iLineId` The ID of the voice line that you want to activate. This is the ID returned by a previous call to the [TelSpcAcceptCall](#) function.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

## Telephony Calls

### Telephony Calls Functions

---

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the iLineId parameter.
functionId	kTelSpcSelectLineMessage

**Comments** If a line was active previous to completion of this function, that line is put on hold. Note that there can only be one line active at any given time, and there can only be one line on hold at any given time. Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcConference](#)

## TelSpcSendBurstDTMF

**Purpose** Send a string of dual-tone, multi-frequency sounds to the network system. Note that you can only play a DTMF while a voice telephone call is active.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSpcSendBurstDTMF(UInt16 iRefnum,  
TelAppID iAppId, const Char \*iDTMFStringP,  
UInt16 \*ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.

-> `iDTMFStringP` A null-terminated string of keytone values. Each byte of the string specifies one of the [Keycode Constants](#).

<-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously. If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

<code>returnCode</code>	<code>errNone</code> upon success or an error code upon failure.
<code>transId</code>	The transaction ID of the operation.
<code>paramP</code>	Points to the string passed to this function in the <code>iDTMFStringP</code> parameter.
<code>functionId</code>	<code>kTelSpcSendBurstDTMFMessage</code>

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iDTMFStringP` remains in memory until the asynchronous call completes.

---

**Comments** This function sends a burst string of keytones to the network. Each key tone is played for the default duration defined by the network. Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

## Telephony Calls

### Telephony Calls Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcPlayDTMF](#), [TelSpcStartContinuousDTMF](#),  
[TelSpcStopContinuousDTMF](#)

## TelSpcStartContinuousDTMF

**Purpose** Send a continuous dual-tone, multi-frequency sound to the network system. Note that you can only play a DTMF while a voice telephone call is active.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSpcStartContinuousDTMF(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iKeyCode,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `iKeyCode` The keycode to send to the network. This must be one of the [Keycode Constants](#).
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the iKeyCode parameter.
functionId	kTelSpcStartContinuousDTMFMessage

**Comments** This function sends a key tone to the network system that is played continuously until the [TelSpcStopContinuousDTMF](#) function executes.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcPlayDTMF](#), [TelSpcSendBurstDTMF](#), [TelSpcStopContinuousDTMF](#)

## TelSpcStopContinuousDTMF

**Purpose** Stop the continuous playing of a tone that was started by calling the [TelSpcStartContinuousDTMF](#) function.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSpcStopContinuousDTMF(UInt16 iRefnum, TelAppID iAppId, UInt16 \*ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.

## Telephony Calls

### Telephony Calls Functions

---

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`            A `NULL` pointer.

`functionId`        `kTelSpcStopContinuousDTMFMessage`

**Comments** This function stops the continuous playing of the tone that was previously initiated by calling the [TelSpcStartContinuousDTMF](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSpcServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSpcPlayDTMF](#), [TelSpcSendBurstDTMF](#),  
[TelSpcStartContinuousDTMF](#)

# Telephony SMS

---

This chapter describes the telephony SMS service set of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony SMS Data Structures](#)
- [Telephony SMS Constants](#)
- [Telephony SMS Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony SMS Data Structures

This section describes the data structures used with the SMS service set of the telephony API.

### TelSmsDateTimeType

Several of the other data structures used with the Telephony SMS functions include an `TelSmsDateTimeType` structure to store a date and time value.

```
typedef _TelSmsDateTimeType
    Boolean    absolute;
    UInt32     dateTime;
} TelSmsDateTimeType
```

## Telephony SMS

### Telephony SMS Data Structures

---

#### Field Descriptions

-> `absolute` If `true`, the `dateTime` value is a Palm™ absolute time value, which is the number of seconds since 1/1/1904. If `false`, the `dateTime` value is relative to the current date and time.

-> `dateTime` The date and time value.

If the `absolute` field is `true`, this is expressed as the number of seconds elapsed since 12:00 A.M. on January 1, 1904. This is the format returned by the [TimGetSeconds](#) function.

If the `absolute` field is `false`, this is expressed as the number of seconds elapsed from the current time.

#### TelSmsDeleteMessageType

The [TelSmsDeleteMessage](#) function uses a `TelSmsDeleteMessageType` structure to specify the message to be deleted.

```
typedef struct _TelSmsDeleteMessageType
    UInt8    messageType;
    UInt16   index;
} TelSmsDeleteMessageType
```

#### Field Descriptions

-> `messageType` The message type. This is one of the [SMS Message Type Constants](#).

-> `index` The index of the SMS message in the phone's storage that is to be deleted. Note that the message is deleted from the storage area selected by a call to the [TelSmsSelectStorage](#) function.

Note that the index is zero-based.

## TelSmsDeliveryAdvancedCDMAType

The [TelSmsDeliveryMessageType](#) structure includes a `TelSmsDeliveryAdvancedCDMAType` structure for CDMA messages.

```
typedef struct _TelSmsDeliveryAdvancedCDMAType
{
    UInt8          messageType;
    TelSmsDateTimeType validityPeriod;
    UInt8          priority;
    UInt8          privacy;
    Boolean        alertOnDeliveryRequest;
    Boolean        manualAckRequest;
    UInt8          voiceMessageNumber;
    UInt8          callbackNumberSize;
    Char           *callbackNumberAddress;
    UInt8          languageIndicator;
} TelSmsDeliveryAdvancedCDMAType
```

### Field Descriptions

<code>messageType</code>	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
<code>validityPeriod</code>	An <a href="#">TelSmsDateTimeType</a> structure that specifies the amount of time for which the message is valid.
<code>priority</code>	The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> .
<code>privacy</code>	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
<code>alertOnDeliveryRequest</code>	true if the user is to be alerted upon delivery of this message, and false if not.
<code>manualAckRequest</code>	true if a reply is requested from the user, and false if not.
<code>voiceMessageNumber</code>	

## Telephony SMS

### Telephony SMS Data Structures

---

<code>callbackNumberSize</code>	<p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>callbackNumberAddress</code> string.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>callbackNumberAddress</code>	<p>A buffer into which the callback number address string is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>languageIndicator</code>	

## TelSmsDeliveryAdvancedGSMTType

The [TelSmsDeliveryMessageType](#) structure includes a `TelSmsDeliveryAdvancedGSMTType` structure for GSM messages.

```
typedef struct _TelSmsDeliveryAdvancedGSMTType
{
    UInt16    protocolId;
    Boolean   replyPath;
    Char      *serviceCenterNumber;
    UInt8     serviceCenterNumberSize;
} TelSmsDeliveryAdvancedGSMTType
```

### Field Descriptions

<code>&lt;- protocolId</code>	The protocol used for this message. This is one of the <a href="#">SMS Message Transport Protocol Constants</a> .
<code>&lt;- replyPath</code>	If this value is set, then you use the <code>serviceCenterNumber</code> to reply to this message.  If this value is not set, you use the default service center provided by your network operator.
<code>&lt;-&gt; serviceCenterNumber</code>	A buffer into which the service center number string is stored.  Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.
<code>&lt;-&gt; serviceCenterNumberSize</code>	When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>serviceCenterNumber</code> string.  Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.

### TelSmsDeliveryAdvancedTDMAType

The [TelSmsDeliveryMessageType](#) structure includes a `TelSmsDeliveryAdvancedTDMAType` structure for TDMA messages.

```
typedef struct _TelSmsDeliveryAdvancedTDMAType
{
    UInt8                messageType;
    TelSmsDateTimeType   validityPeriod;
    UInt8                priority;
```

## Telephony SMS

### Telephony SMS Data Structures

---

```
    UInt8          privacy;
    Boolean        alertOnDeliveryRequest;
    Boolean        manualAckRequest;
    UInt8         voiceMessageNumber;
    UInt8         callbackNumberSize;
    Char          *callbackNumberAddress;
    UInt8         languageIndicator;
} TelSmsDeliveryAdvancedTDMAType
```

#### Field Descriptions

messageType	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
validityPeriod	An <a href="#">TelSmsDateTimeType</a> structure that specifies the amount of time for which the message is valid.
priority	The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> .
privacy	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
alertOnDeliveryRequest	true if the user is to be alerted upon delivery of this message, and false if not.
manualAckRequest	true if a reply is requested from the user, and false if not.
voiceMessageNumber	
callbackNumberSize	When the structure is used as an input parameter, this is the allocated size, in bytes, of the callbackNumberAddress string.  Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a telErrBufferSize error.

`callbackNumberAddress` A buffer into which the callback telephone number address string is stored.

Note that if this buffer is too small to contain the entire retrieved string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

`languageIndicator`

## TelSmsDeliveryMessageType

The [TelSmsReadMessage](#) function uses a `TelSmsDeliveryMessageType` structure to retrieve information about a delivered message.

```
typedef struct _TelSmsDeliveryMessageType
{
    UInt16          version;
    UInt16          index;
    UInt32          messageIdentifier;
    TelSmsDateTimeType  timeStamp;
    UInt16          dataSize;
    UInt8           *data;
    UInt8           dataCodingScheme;
    UInt8           originatingAddressSize;
    Char            *originatingAddress;
    Boolean         otherToReceive;
    Boolean         reportDeliveryIndicator;
    UInt8           standardType;

    union
    {
        TelSmsDeliveryAdvancedGSMTType
                                advancedGSM;
        TelSmsDeliveryAdvancedCDMAType
                                advancedCDMA;
        TelSmsDeliveryAdvancedTDMAType
                                advancedTDMA;
    } advancedParams;
}
```

## Telephony SMS

### Telephony SMS Data Structures

---

```
    UInt8                extensionsCount;  
    TelSmsExtensionType *extensionsP;  
} TelSmsDeliveryMessageType
```

#### Field Descriptions

-> version	The version of the SMS API associated with this message.
<-> index	Upon return, the SMS index of the message on the phone. This is a 0-based index.  This value is used for input only when calling the <a href="#">TelSmsReadMessage</a> function to read one SMS at a time.
<- messageIdentifier	The message identifier.
<- timeStamp	The message time stamp. This is a <a href="#">TelSmsDateTimeType</a> structure.
<-> dataSize	The size of the data buffer.  When the structure is used as an input parameter, this is the allocated size of the data buffer.  Upon return, this is the actual size of the message data. If the buffer is too small to contain the entire message, this field is assigned the entire length of the message, and the function using this structure generates a <code>telErrBufferSize</code> error.
<-> data	A buffer into which the retrieved data is stored.  Note that if this buffer is too small to contain the entire retrieved message, the end of the message is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.
<- dataCodingScheme	The coding scheme used for the data. This is one of the <a href="#">SMS Data Coding Scheme Constants</a> .

- `<-> originatingAddressSize` The size of the `originatingAddress` buffer.
- When the structure is used as an input parameter, this is the allocated size of the `originatingAddress` buffer.
- Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.
- `<-> originatingAddress` A buffer into which the originating address string is stored.
- Note that if this buffer is too small to contain the entire string, the end of the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.
- `<- otherToReceive` Indicates whether there are more messages waiting to be received from the service center to the mobile device.
- `<- reportDeliveryIndicator` If `true`, indicates that the originating user has asked the network to send a delivery report.
- `<- standardType` Indicates which field of the `advancedParams` union contains the message information. This is one of the [Network Type Constants](#) described in [Chapter 70, "Telephony Network."](#)
- If this value is `kTelNwkCDMA`, then the `advancedParams` union contains a [TelSmsDeliveryAdvancedCDMAType](#) structure, and similarly for the other values.

## Telephony SMS

### Telephony SMS Data Structures

---

<code>advancedParams</code>	Advanced message information for GSM, CDMA, or TDMA messages. This is one of the following structure types: <a href="#">TelSmsDeliveryAdvancedGSMTType</a> <a href="#">TelSmsDeliveryAdvancedCDMAType</a> <a href="#">TelSmsDeliveryAdvancedTDMAType</a>
<code>&lt;-&gt; extensionsCount</code>	On input, this is the number of extension structures allocated for this message. You must allocate at least one structure to specify the multipart information.  Upon return, this is the number of extensions in the SMS header. If the SMS header contains more extensions than you have allocated, the available extension structures are filled, and this function generates a <code>telErrBufferSize</code> error.
<code>&lt;-&gt; extensionsP</code>	A pointer to an array of <a href="#">TelSmsExtensionType</a> structures that you have allocated for this message. You must allocate this array before using this structure.

## TelSmsExtensionType

The `TelSmsExtensionType` structure specifies multipart information about a message.

```
typedef struct _TelSmsExtensionType
{
    UInt8      extensionTypeId;
    union
    {
        TelSmsMultiPartExtensionType    mp;
        TelSmsNbsExtensionType          nbs;
        TelSmsUserExtensionType         user;
    } extension;
} TelSmsExtensionType
```

### Field Descriptions

`<-> extensionTypeId` Identifies the type of SMS extension structure found in the extension union. This is one of the [SMS Extension Type Constants](#).

If the value of this field is `kTelSmsMultipartExtensionTypeId`, then the extension union contains a [TelSmsMultiPartExtensionType](#) structure.

If the value of this field is `kTelSmsNbsExtensionTypeId` or `kTelSmsNbs2ExtensionTypeId`, then the union contains a [TelSmsNbsExtensionType](#) structure. The difference between these two is that `kTelSmsNbs2ExtensionTypeId` indicates that the port value is a long instead of a short.

If this field contains any other value, then the union contains a [TelSmsUserExtensionType](#) structure.

`<- extension` The extension information, which is one of the following structure types:  
[TelSmsMultiPartExtensionType](#)  
[TelSmsNbsExtensionType](#)  
[TelSmsUserExtensionType](#)

### TelSmsGetAvailableStorageType

The [TelSmsGetAvailableStorage](#) function uses a `TelSmsGetAvailableStorageType` structure to retrieve information about the storage available on the phone.

```
typedef struct _TelSmsGetAvailableStorageType
{
    UInt16    count;
    UInt8     *storagesP;
} TelSmsGetAvailableStorageType
```

## Telephony SMS

### Telephony SMS Data Structures

---

#### Field Descriptions

<-> count	The size of the storagesP buffer.  When the structure is used as an input parameter, this is the allocated number of values in the buffer. Upon return, this is the total number of storage areas in the phone.
<- storagesP	A buffer into which the retrieved storage IDs are stored. Each value stored into the buffer is one of the <a href="#">SMS Storage ID Constants</a> .

#### TelSmsGetMessageCountType

The [TelSmsGetMessageCount](#) function uses a `TelSmsGetMessageCountType` structure to retrieve information about messages in the currently selected storage.

```
typedef struct _TelSmsGetMessageCountType
{
    UInt8    messageType;
    UInt16   slots;
    UInt16   count;
} TelSmsGetMessageCountType
```

#### Field Descriptions

-> messageType	The type of message for which you want to retrieve the count. This must be one of the <a href="#">SMS Message Type Constants</a> .  You must fill this in on input to the <a href="#">TelSmsGetMessageCount</a> function.
<- slots	The total number of message slots available in the currently selected storage area (for all message types).
<- count	The number of filled slots for the specified messageType in the currently selected storage area.

## TelSmsManualAckType

The [TelSmsSendManualAcknowledge](#) function uses a `TelSmsManualAckType` structure to specify the information used to send a message acknowledgment.

```
typedef struct _TelSmsManualAckType
{
    UInt16      version;
    Char        *destinationAddress;
    UInt32      messageId;
    UInt16      dataSize;
    UInt8       *data;
    UInt8       dataCodingScheme;
    UInt8       responseCode;
} TelSmsManualAckType
```

### Field Descriptions

<code>version</code>	The version of the SMS API used for this acknowledgment.
<code>destinationAddress</code>	The destination address. For GSM, the length of this address is 12 bytes. For CDMA, the length is up to 128 bytes.
<code>messageId</code>	Upon return, the ID of the acknowledgment.
<code>dataSize</code>	The size of the data buffer.  When the structure is used as an input parameter, this is the allocated size of the data buffer.  Upon return, this is the actual size of the data. If the buffer is too small to contain all of the data, this field is assigned the entire length of the data, and the function using this structure generates a <code>telErrBufferSize</code> error.
<code>data</code>	A buffer into which the retrieved data is stored.  Note that if this buffer is too small to contain the all of the retrieved data, the data is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.

## Telephony SMS

### Telephony SMS Data Structures

---

dataCodingScheme	The coding scheme used for the data. This must be one of the <a href="#">SMS Data Coding Scheme Constants</a> .
responseCode	The response code. The value of this field depends on the network being used.

## TelSmsMultiPartExtensionType

The [TelSmsExtensionType](#) structure uses a `TelSmsMultiPartExtensionType` structure to describe information about a multipart message.

```
typedef struct _TelSmsMultiPartExtensionType
    UInt16  bytesSent;
    UInt16  partCurrent;
    UInt16  partCount;
    UInt16  partId;
} TelSmsMultiPartExtensionType
```

### Field Descriptions

<-> bytesSent	On input, set this value to 0.  Upon return, this is the current count of message bytes that have been sent.
<-> partCurrent	On input, set this value to 0.  Upon return, this is the part number of the current message part.

<code>&lt;-&gt; partCount</code>	<p>On input, set this value to 0.</p> <p>Upon return, this is the number of message parts required to send the data.</p>
<code>&lt;-&gt; partId</code>	<p>The ID of the current SMS message. This ID is unique and is the same for all parts of the message. This information is required to reassemble a multi-part SMS.</p> <p>On input, set this value to 0.</p>

## TelSmsNbsExtensionType

The [TelSmsExtensionType](#) structure uses a `TelSmsNbsExtensionType` structure to describe information about a NBS message.

```
typedef struct _TelSmsNbsExtensionType
    UInt16  destPort;
    UInt16  srcPort;
} TelSmsNbsExtensionType
```

### Field Descriptions

<code>&lt;-&gt; destPort</code>	<p>When the structure is used for input, this is the NBS port number used to encode the data.</p> <p>Upon return, this is the NBS port number that was used for the data.</p>
<code>&lt;-&gt; srcPort</code>	<p>This is currently the same as the <code>destPort</code>.</p>

## TelSmsReadMessagesType

The [TelSmsReadMessages](#) function uses a `TelSmsReadMessagesType` structure to retrieve messages from the currently selected storage area.

```
typedef struct _TelSmsReadMessagesType
    UInt16          first;
    UInt16          count;
    TelSmsDeliveryMessageType *messagesP;
```

## Telephony SMS

### Telephony SMS Data Structures

---

```
} TelSmsReadMessagesType
```

#### Field Descriptions

-> first	The index of the first message to retrieve. Message indexes are zero-based.
<-> count	The size of the messagesP buffer.  When the structure is used as an input parameter, this is the allocated number of pointers in the messagesP buffer.  Upon return, this is the number of messages that could be retrieved. If the messagesP buffer is too small to contain all of the messages, this field is assigned the entire count, and the function using this structure generates a telErrBufferSize error.
<-> messagesP	An array of pointers to <a href="#">TelSmsDeliveryMessageType</a> structures, each of which is filled in with a retrieved message, if available.

#### TelSmsReadReportsType

The [TelSmsReadReports](#) function uses a `TelSmsReadReportsType` structure to retrieve reports from the currently selected storage area.

```
typedef struct _TelSmsReadReportsType
    UInt16          first;
    UInt16          count;
    TelSmsReportType *reportsP;
} TelSmsReadReportsType
```

### Field Descriptions

-> first	The index of the first report to retrieve. Report indexes are zero-based.
<-> count	<p>The size of the <code>reportsP</code> buffer.</p> <p>When the structure is used as an input parameter, this is the allocated number of pointers in the <code>reportsP</code> buffer.</p> <p>Upon return, this is the actual number of reports that could be read. If the buffer is too small to contain all of the reports, this field is assigned the entire count, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<-> reportsP	<p>An array of pointers to <a href="#">TelSmsReportType</a> structures, each of which is filled in with a retrieved message, if available.</p> <p>Note that if this buffer is too small to contain all of the retrieved reports, the function using this structure generates a <code>telErrBufferSize</code> error.</p>

### TelSmsReadSubmittedMessagesType

The [TelSmsReadSubmittedMessages](#) function uses a `TelSmsReadSubmittedMessagesType` structure to retrieve submitted messages from the currently selected storage area.

```
typedef struct _TelSmsReadMessagesType
    UInt16          first;
    UInt16          count;
    TelSmsDeliveryMessageType *submittedsP;
} TelSmsReadSubmittedMessagesType
```

## Telephony SMS

### Telephony SMS Data Structures

---

#### Field Descriptions

-> first	The index of the first message to retrieve. Message indexes are zero-based.
<-> count	The size of the <code>submittedSP</code> buffer.  When the structure is used as an input parameter, this is the allocated number of pointers in the <code>submittedSP</code> buffer. Upon return, this is the number of messages that were actually read.
<-> <code>submittedSP</code>	An array of pointers to <a href="#">TelSmsSubmittedMessageType</a> structures, each of which is filled in with a retrieved message, if available.

#### TelSmsReportType

The [TelSmsReadReport](#) function uses a `TelSmsReportType` structure to retrieve a report from the report storage area.

```
typedef struct _TelSmsReportType
{
    UInt16          version;
    UInt16          index;
    UInt8           reportType;
    UInt32          messageId;
    UInt16          dataSize;
    UInt8           *data;
    UInt8           dataCodingScheme;
    Char            *originatingAddress;
    UInt8           originatingAddressSize;
    UInt8           report;
    TelSmsDateTimeType timeStamp;
} TelSmsReportType
```

#### Field Descriptions

-> version	
<- index	The index of the report in the phone storage area.
<- reportType	The delivery report type.

<code>&lt;- messageId</code>	The message ID.
<code>&lt;-&gt; dataSize</code>	<p>The size of the data buffer.</p> <p>When the structure is used as an input parameter, this is the allocated size of the data buffer.</p> <p>Upon return, this is the actual size of the data. If the buffer is too small to contain all of the data, this field is assigned the entire length of the data, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>&lt;-&gt; data</code>	<p>A buffer into which the retrieved data is stored.</p> <p>Note that if this buffer is too small to contain the all of the retrieved data, the data is truncated and the function using this structure generates a <code>telErrBufferSize</code> error.</p>
<code>&lt;- dataCodingScheme</code>	The encoding scheme used for the report data. This must be one of the <a href="#">SMS Data Coding Scheme Constants</a> .
<code>&lt;-&gt; originatingAddress</code>	<p>A buffer into which the originating address is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBuffrSize</code> error.</p>
<code>&lt;-&gt; originatingAddressSize</code>	<p>The size of the <code>originatingAddress</code> buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>

## Telephony SMS

### Telephony SMS Data Structures

---

<- report	The ID of the delivery confirmation report associated with the message.
<- timeStamp	An <a href="#">TelSmsDateTimeType</a> structure that stores the time at which the message corresponding to the report was received.

## TelSmsSendMessageType

```
typedef struct _TelSmsSendMessageType
{
    UInt32                messageId;
    TelSmsSubmitMessageType message;
} TelSmsSendMessageType
```

### Field Descriptions

<- messageId	The SMS ID that was assigned by the telephone to the outgoing message.  For a multi-part message, each part has its own message ID.
-> message	A structure of type <a href="#">TelSmsSubmitMessageType</a> that contains the message data and parameters.

## TelSmsSubmitAdvancedCDMAType

The [TelSmsSubmitMessageType](#) structure includes a [TelSmsSubmitAdvancedCDMAType](#) structure for CDMA messages.

```
typedef struct _TelSmsSubmitAdvancedCDMAType
{
    Boolean                manualAckRequest;
    UInt8                  messageType;
    TelSmsDateTimeType    deferredDate;
    UInt8                  priority;
    UInt8                  privacy;
    Boolean                alertOnDeliveryRequest;
    Char                   *callbackNumber;
    UInt8                  callbackNumberSize;
}
```

} TelSmsSubmitAdvancedCDMAType

### Field Descriptions

<code>manualAckRequest</code>	true if a reply is requested from the user, and false if not.
<code>messageType</code>	The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .
<code>deferredDate</code>	
<code>priority</code>	
<code>privacy</code>	The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .
<code>alertOnDeliveryRequest</code>	true if the user is to be alerted upon delivery of this message, and false if not.
<code>callbackNumber</code>	A buffer into which the retrieved callback telephone number string is stored.  Note that if this buffer is too small to contain the entire retrieved string, the string is truncated (and ends with the null terminator character) and the function using this structure generates a <code>telErrBufferSize</code> error.
<code>callbackNumberSize</code>	When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>callbackNumber</code> string.  Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.

### **TelSmsSubmitAdvancedGSMTType**

The [TelSmsSubmitMessageType](#) structure includes a `TelSmsSubmitAdvancedGSMTType` structure for GSM messages.

## Telephony SMS

### Telephony SMS Data Structures

---

```
typedef struct _TelSmsSubmitAdvancedGSMTType
{
    UInt16      protocolId;
    Boolean     rejectDuplicatedRequest;
    Boolean     replyPath;
    Char        *serviceCenterNumber;
    UInt8       serviceCenterNumberSize;
} TelSmsSubmitAdvancedGSMTType
```

#### Field Descriptions

- > `protocolId` Specifies gateway information for routing a message to another transport.
- Some service centers provide a gateway between SMS and other transports such as mail and FAX. Service centers may reject messages with `protocolId` values that are reserved or unsupported.
- The mobile device does not interpret reserved or unsupported values, but does store them as received.
- > `rejectDuplicatedRequest` A Boolean value that specifies if the service center should accept a submit message for a submit message that is still held in the service center when that message has the same identifier and destination address as a previously submitted message from the same originating address.
- > `replyPath` The path that the service center can use to deliver a reply to the originating message.
- The reply path is requested by the originating mobile device by setting the `replyPath` parameter in the original submit message.
- If the service center supports reply path requests from the mobile device, the service center sets the `replyPath` parameter in the response.

- > `serviceCenterNumber`      A buffer containing the service telephone number string.
  
- > `serviceCenterNumberSize`    The allocated size, in bytes, of the `serviceCenterNumber` string.

## **TelSmsSubmitAdvancedTDMAType**

The [TelSmsSubmitMessageType](#) structure includes a `TelSmsSubmitAdvancedTDMAType` structure for TDMA messages.

```
typedef struct _TelSmsSubmitAdvancedTDMAType
{
    Boolean                manualAckRequest;
    UInt8                 messageType;
    TelSmsDateTimeType   deferredDate;
    UInt8                 priority;
    UInt8                 privacy;
    Boolean                alertOnDeliveryRequest;
    Char                  *callbackNumber;
    UInt8                 callbackNumberSize;
} TelSmsSubmitAdvancedTDMAType
```

### **Field Descriptions**

- |                                     |  |
|-------------------------------------|--|
| <code>manualAckRequest</code>       | true if a reply is requested from the user, and false if not.  |
| <code>messageType</code>            | The type of the message. This must be one of the <a href="#">SMS Message Type Constants</a> .            |
| <code>deferredDate</code>           |  |
| <code>priority</code>               |  |
| <code>privacy</code>                | The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> . |
| <code>alertOnDeliveryRequest</code> | true if the user is to be alerted upon delivery of this message, and false if not.                       |

## Telephony SMS

### Telephony SMS Data Structures

---

`callbackNumber` A buffer into which the retrieved callback telephone number string is stored.

Note that if this buffer is too small to contain the entire retrieved string, the string is truncated (and ends with the null terminator character) and the function using this structure generates a `telErrBufferSize` error.

`callbackNumberSize` When the structure is used as an input parameter, this is the allocated size, in bytes, of the `callbackNumber` string.

Upon return, this is the actual size of the string, including the null terminator character. If the buffer is too small to contain the entire retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

## TelSmsSubmitMessageType

The [TelSmsReadReports](#) and [TelSmsSendMessageType](#) structures use a `TelSmsSubmitMessageType` structure to store reports retrieved from the currently selected storage area.

```
typedef struct _TelSmsSubmitMessageType
{
    UInt16          version;
    Boolean          networkDeliveryRequest;
    Char            *destinationAddress;
    UInt8           destinationAddressSize;
    UInt16          dataSize;
    UInt8           *data;
    UInt8           dataCodingScheme;
    TelSmsDateTimeType validityPeriod;
    UInt8           standardType;
    union
    {
        TelSmsSubmitAdvancedGSMTType    advancedGSM;
        TelSmsSubmitAdvancedCDMAType    advancedCDMA;
    }
};
```

```
        TelSmsSubmitAdvancedTDMAType  advancedTDMA;  
    } advancedParams;  
    UInt8                               extensionsCount;  
    TelSmsExtensionType                 *extensionsP;  
} TelSmsSubmitMessageType
```

### Field Descriptions

- > `version`                      The version of the SMS API associated with this message.
  
- > `networkDeliveryRequest`      If this value is true, the service center accepts the submit message.
  
- <-> `destinationAddress`          A buffer that contains the phone number of the message recipient.
  
- <-> `destinationAddressSize`      The size of the destination address string.
  
- <-> `dataSize`                      The size of the data buffer.
  
- <-> `data`                          A buffer into which the retrieved message data is stored.
  
- > `dataCodingScheme`              The coding scheme used for the data. This is one of the [SMS Data Coding Scheme Constants](#).
  
- > `validityPeriod`                An [TelSmsDateTimeType](#) structure that specifies the amount of time for which the message is valid.
  
- > `standardType`                   Indicates which field of the `advancedParams` union contains the message information. This must be one of the [Network Type Constants](#) described in [Chapter 70, "Telephony Network."](#)  
  
If this value is `kTelNwkCDMA`, then the `advancedParams` union contains a [TelSmsDeliveryAdvancedCDMAType](#) structure, and similarly for the other values.

## Telephony SMS

### Telephony SMS Data Structures

---

-> advancedParams	Advanced message information for GSM, CDMA, or TDMA messages. This is a pointer to one of the following structure types: <a href="#">TelSmsSubmitAdvancedCDMAType</a> <a href="#">TelSmsDeliveryAdvancedGSMTType</a> <a href="#">TelSmsDeliveryAdvancedTDMAType</a>
<-> extensionsCount	The number of extension structures allocated for this message. You must allocate at least one structure to specify the multipart information.
<-> extensionsP	A pointer to an array of <a href="#">TelSmsExtensionType</a> structures that you have allocated for this message.

## TelSmsSubmittedMessageType

The [TelSmsReadSubmittedMessage](#) function uses a [TelSmsSubmittedMessageType](#) structure to retrieve reports from the currently selected storage area.

```
typedef struct _TelSmsSubmittedMessageType
{
    UInt16          index;
    TelSmsSubmitMessageType message;
} TelSmsSubmittedMessageType
```

### Field Descriptions

-> index	The index of the message on the phone.
<- message	A <a href="#">TelSmsSubmitMessageType</a> structure that represents the message.

## TelSmsUserExtensionType

The [TelSmsExtensionType](#) structure uses a [TelSmsUserExtensionType](#) structure to describe a user-defined extended message header.

```
typedef struct _TelSmsUserExtensionType
    UInt8      *extHeader;
    UInt8      extHeaderSize;
} TelSmsUserExtensionType
```

### Field Descriptions

<code>&lt;-&gt; extHeader</code>	On input, this field must be set to 0.  Upon return, this is a pointer to the user-defined header content.
<code>&lt;-&gt; extHeaderSize</code>	On input, this field must be set to 0.  Upon return, this is the size of the user-defined header content.

## Telephony SMS Constants

This section describes the constants used with the SMS service set of the telephony API.

### SMS Extension Type Constants

The SMS extension type constants describe the type of extension used to represent part of a message.

Constant	Value	Description
<code>kTelSmsMultiPartExtensionTypeId</code>	0x00	A multipart short message.
<code>kTelSmsNbsExtensionTypeId</code>	0x04	An NBS message with short port number value.
<code>kTelSmsNbs2ExtensionTypeId</code>	0x05	An NBS message with long port number value.
(any other value)		A user-defined extension type.

### SMS Message Type Constants

The SMS message type constants describe the delivery type of a message.

## Telephony SMS

### Telephony SMS Constants

---

Constant	Value	Description
kTelSmsMessageTypeDelivered	0	A delivered message.
kTelSmsMessageTypeReport	1	A report message.
kTelSmsMessageTypeSubmitted	2	A submitted message.
kTelSmsMessageTypeManualAck	3	A manual acknowledgement message.
kTelSmsMessageTypeAllTypes	4	All messages.

---

## SMS Message Transport Protocol Constants

The SMS message transport protocol constants describe the protocol used to deliver a message.

Constant	Value	Description
ktelSmsDefaultProtocol	0	The default message transport protocol.
kTelSmsFaxProtocol	1	A FAX message.
kTelSmsX400Protocol	2	An X.400 message.
kTelSmsPagingProtocol	3	A paged message.
kTelSmsEmailProtocol	4	An email message.
kTelSmsErmesProtocol	5	An Ermes message.
kTelSmsVoiceProtocol	6	A voice message.

---

## SMS Storage ID Constants

The SMS storage ID constants describe the storage location of a message.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelSmsStorageSIM</code>	0	Stored in the SIM.
<code>kTelSmsStoragePhone</code>	1	Stored in the phone.
<code>kTelSmsStorageAdaptor</code>	2	Stored in the telephone adaptor.
<code>kTelSmsStorageFirstOem</code>	3	Storage managed by the OEM.  This constant specifies the first OEM storage area. You can specify additional OEM storage areas by incrementing this value. For example, to specify the third OEM storage area, use the following:  <code>kTelSmsStorageFirstOem+2</code>

---

## SMS Data Coding Scheme Constants

The SMS data coding scheme constants describe the encoding used for SMS data.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kTelSms8BitsEncoding</code>	0	8-bit encoding.
<code>kTelSmsBitsASCIIEncoding</code>	1	ANSI X3.4 encoding.
<code>kTelSmsIA5Encoding</code>	2	CCITT T.50 encoding.
<code>kTelSmsIS91Encoding</code>	3	TIA/EIA/IS-91 section 3.7.1 encoding.
<code>kTelSmsUCS2Encoding</code>	4	UCS2 encoding; used with GSM only.
<code>kTelSmsDefaultGSMEncoding</code>	5	Default encoding for GSM only.

---

## Telephony SMS

### Telephony SMS Functions

---

### SMS Message Urgency Constants

The SMS message urgency constants describe the priority level of a message in a [TelSmsDeliveryAdvancedCDMAType](#) or [TelSmsDeliveryAdvancedTDMAType](#) structure.

Constant	Value	Description
kTelSmsUrgencyNormal	0	Normal urgency.
kTelSmsUrgencyUrgent	1	An urgent message.
kTelSmsUrgencyEmergency	2	An emergency message.

### SMS Message Privacy Constants

The SMS message privacy constants describe the privacy type of a message in a CDMA or TDMA advanced parameters.

Constant	Value	Description
kTelSmsPrivacyNotRestricted	0	Privacy level 0.
kTelSmsPrivacyRestricted	1	Privacy level 1.
kTelSmsPrivacyConfidential	2	Privacy level 2.
kTelSmsPrivacySecret	3	Privacy level 3.

## Telephony SMS Functions

This section describes the functions used with the SMS service set of the telephony API.

## TelSmsDeleteMessage

<b>Purpose</b>	Delete an SMS report, delivered message, or submitted message.								
<b>Declared In</b>	TelephonyMgr.h								
<b>Prototype</b>	<pre>Err TelSmsDeleteMessage(UInt16 iRefnum, TelAppID iAppId, TelSmsDeleteMessageType *ioParamP, UInt16 *ioTransIdP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; iRefnum</td><td>The telephony manager library reference number.</td></tr><tr><td>-&gt; iAppId</td><td>The telephone application attachment identifier for your application.</td></tr><tr><td>&lt;-&gt; ioParamP</td><td>A pointer to a <a href="#">TelSmsDeleteMessageType</a> structure that specifies the index and type of the message to delete.</td></tr><tr><td>&lt;-&gt; ioTransIdP</td><td>Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</td></tr></table>	-> iRefnum	The telephony manager library reference number.	-> iAppId	The telephone application attachment identifier for your application.	<-> ioParamP	A pointer to a <a href="#">TelSmsDeleteMessageType</a> structure that specifies the index and type of the message to delete.	<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.
-> iRefnum	The telephony manager library reference number.								
-> iAppId	The telephone application attachment identifier for your application.								
<-> ioParamP	A pointer to a <a href="#">TelSmsDeleteMessageType</a> structure that specifies the index and type of the message to delete.								
<-> ioTransIdP	Set the value of this parameter to NULL to cause the function to execute synchronously.  If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.								
<b>Synchronous Result</b>	Returns <code>errNone</code> if the function was successful or returns an error code if not successful.								
<b>Asynchronous Result</b>	The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes: <table><tr><td>returnCode</td><td>errNone upon success or an error code upon failure.</td></tr><tr><td>transId</td><td>The transaction ID of the operation.</td></tr></table>	returnCode	errNone upon success or an error code upon failure.	transId	The transaction ID of the operation.				
returnCode	errNone upon success or an error code upon failure.								
transId	The transaction ID of the operation.								

## Telephony SMS

### Telephony SMS Functions

---

paramP	Points to the <a href="#">TelSmsDeleteMessageType</a> structure passed to this function in the iDelInfoP parameter.
functionId	kTelSmsDeleteMessageMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** If the deleted message has been delivered, the deletion is performed in the current storage, which you can set with the [TelSmsSelectStorage](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage](#)

## TelSmsGetAvailableStorage

**Purpose** Retrieve the list of all available storage on the phone.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSmsGetAvailableStorage(UInt16 iRefnum,  
TelAppID iAppId,  
TelSmsGetAvailableStorageType \*ioParamP,  
UInt16 \*ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.

- <-> ioParamP A pointer to a [TelSmsGetAvailableStorageType](#) structure that is filled in with information about the storage areas available on the phone.
- <-> ioTransIdP Set the value of this parameter to NULL to cause the function to execute synchronously.
- If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

- returnCode      `errNone` upon success or an error code upon failure.
- transId          The transaction ID of the operation.
- paramP           Points to the [TelSmsGetAvailableStorageType](#) structure passed to this function in the `ioParamP` parameter.
- functionId       `kTelSmsGetAvailableStorageMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments** The count of storage areas available on the phone is stored into the `count` field of the [TelSmsGetAvailableStorageType](#) structure referenced by `ioParamP`, and the storage ID of each available room is stored into the buffer referenced by the `storagesP` field. If the `storagesP` buffer is too small to contain all of the storage IDs, the buffer is truncated and this function returns the

## Telephony SMS

### Telephony SMS Functions

---

`telErrBufferSize` error. The count field of the structure is always updated to contain the total number of available storage areas on the phone.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage](#)

## TelSmsGetDataMaxSize

**Purpose** Returns the maximum length, in bytes, of a message on the current network.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSmsGetDataMaxSize(UINT16 iRefnum,  
TelAppID iAppId, UINT16 *oSizeP,  
UINT16 *ioTransIdP)`

**Parameters**

<code>-&gt; iRefnum</code>	The telephony manager library reference number.
<code>-&gt; iAppId</code>	The telephone application attachment identifier for your application.
<code>&lt;- oSizeP</code>	A pointer to an unsigned integer value that is updated with the maximum length of an SMS message on the current network.
<code>&lt;-&gt; ioTransIdP</code>	Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.  If this parameter is not <code>NULL</code> , the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode	errNone upon success or an error code upon failure.
transId	The transaction ID of the operation.
paramP	Points to the unsigned integer value passed to this function in the oSizeP parameter.
functionId	kTelGetDataMaxSizeMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oSizeP remains in memory until the asynchronous call completes.

---

**Comments** You can use this function to determine the maximum size you need to allocate to read a message.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsReadMessage](#), [TelSmsReadMessages](#)

## Telephony SMS

### Telephony SMS Functions

---

## TelSmsGetMessageCount

**Purpose** Retrieve the total number of message slots, and the number of filled slots for the specified message type.

**Declared In** `TelephonyMgr.h`

**Prototype**  
`Err TelSmsGetMessageCount (UInt16 iRefnum,  
TelAppID iAppId,  
TelSmsGetMessageCountType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioParamP` A pointer to a [TelSmsGetMessageCountType](#) structure that specifies the message type and is filled in with the count information.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

paramP	Points to the <a href="#">TelSmsGetMessageCountType</a> structure passed to this function in the ioParamP parameter.
functionId	kTelSmsGetMessageCountMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioParamP remains in memory until the asynchronous call completes.

---

**Comments** The currently selected storage area pertains only to delivered messages; other message types are stored on the phone, but not in a specific storage area. If you specify delivered messages, this function retrieves information about the messages in the currently selected SMS storage area on the phone. If you specify a different message type, this function retrieves information about the messages in the phone.

You specify the message type by assigning one of the [SMS Message Type Constants](#) to the messageType field of the TelSmsGetMessageCountType structure before calling this function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage](#)

## Telephony SMS

### Telephony SMS Functions

---

## TelSmsGetSelectedStorage

**Purpose** Retrieve the ID of the currently selected storage area on the phone.

**Declared In** TelephonyMgr.h

**Prototype** `Err TelSmsGetSelectedStorage(UInt16 iRefnum, TelAppID iAppId, UInt8 *oStorageIdP, UInt16 *ioTransIdP)`

**Parameters**

- > iRefnum The telephony manager library reference number.
- > iAppId The telephone application attachment identifier for your application.
- <- oStorageIdP A pointer to an unsigned byte value that is assigned the ID of the currently selected storage area on the phone. The assigned ID value is one of the [SMS Storage ID Constants](#).
- <-> ioTransIdP Set the value of this parameter to NULL to cause the function to execute synchronously.  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

returnCode      `errNone` upon success or an error code upon failure.

transId          The transaction ID of the operation.

paramP	Points to the unsigned integer value passed to this function in the oStorageIdP parameter.
functionId	kTelGetSelectedStorageMessage

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by oStorageIdP remains in memory until the asynchronous call completes.

---

**Comments** The currently selected storage area pertains only to delivered messages; other message types are stored on the phone, but not in a specific storage area.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage](#)

## TelSmsGetUniquePartId

**Purpose** Return a unique part identifier to assign to the partId field of a submit message.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSmsGetUniquePartId(UInt16 iRefnum, TelAppID iAppId, UInt16 \*oUniqueIdP, UInt16 \*ioTransIdP)

**Parameters**

-> iRefnum	The telephony manager library reference number.
-> iAppId	The telephone application attachment identifier for your application.
<- oUniqueIdP	A pointer to a unsigned integer value. Upon return, this is the unique part ID value.

## Telephony SMS

### Telephony SMS Functions

---

<-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### Synchronous Result

Returns `errNone` if the function was successful or returns an error code if not successful.

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`            The transaction ID of the operation.

`paramP`            Points to the unsigned integer value passed to this function in the `oUniqueIdP` parameter.

`functionId`        `kTelGetUniquePartIdMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oUniquePartIdP` remains in memory until the asynchronous call completes.

---

#### Comments

This function corresponds to the `kTelUrqSmsGetUniquePartIdMessage` value.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

#### Compatibility

Implemented only if [4.0 New Feature Set](#) is present.

## TelSmsReadMessage

- Purpose** Retrieve a delivered message from the currently selected storage area.
- Declared In** `TelephonyMgr.h`
- Prototype**
- ```
Err TelSmsReadMessage(UInt16 iRefnum,  
TelAppID iAppId,  
TelSmsDeliveryMessageType *ioMessageP,  
UInt16 *ioTransIdP)
```
- Parameters**
- > `iRefnum` The telephony manager library reference number.
  - > `iAppId` The telephone application attachment identifier for your application.
  - <-> `ioMessageP` A pointer to a [TelSmsDeliveryMessageType](#) structure that is filled in with the message.  
  
On input, the `index` field of this structure contains the index of the message that you want retrieved. Message indexes are zero-based.  
  
On input, the `extensionsCount` field specifies the number of extensions allocated in the `extensionsP` array. You must allocate at least one multi-part extension, even for a single-part message.  
  
On input, the `dataSize` field specifies the allocated size of the data buffer, and the `originatingAddressSize` field specifies the allocated size of the `originatingAddress` string. Upon return, each size field specifies the complete size of the data that was stored into the buffer, even if the data had to be truncated to fit.

## Telephony SMS

### Telephony SMS Functions

---

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

#### Synchronous Result

Returns `errNone` if the function was successful or returns an error code if not successful.

#### Asynchronous Result

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`            The transaction ID of the operation.

`paramP`            Points to the [TelSmsDeliveryMessageType](#) structure passed to this function in the `ioMessageP` parameter.

`functionId`        `kTelSmsReadMessageMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioMessageP` remains in memory until the asynchronous call completes.

---

#### Comments

The message data is stored into the `data` field of the [TelSmsDeliveryMessageType](#) structure referenced by `ioMessageP`. If the complete message data is too large to fit into the allocated size of the `data` field, the message data is truncated and this function returns the `telErrBufferSize` error. The `dataSize` field of the structure is always updated to contain the actual size, in bytes, of the message data.

The originating address string is stored into the `originatingData` field of the [TelSmsDeliveryMessageType](#) structure referenced by `ioMessageP`. If the complete string is too large to fit into the allocated size of the `originatingData` field,

the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `originatingAddressSize` field of the structure is always updated to contain the actual size of the string.

Before calling this function, you need to allocate a number of fields and structures in and related to the `TelSmsDeliveryMessage` structure:

- Allocate each address field with a size of at least `kTelMaxPhoneNumberLen + 1`.  
For example, for a GSM message, you must allocate the `originatingAddress` and `serviceCenterNumber` fields in the [TelSmsDeliveryAdvancedGSMType](#) structure in the `TelSmsDeliveryMessage` structure.
- Allocate the message field data to have the maximum size of a message on the current network. You can determine this value by calling the [TelSmsGetDataMaxSize](#) function.
- Allocate at least one [TelSmsExtensionType](#) structure in the `TelSmsDeliveryMessage` structure. You must have at least one extension structure, even if your message has only a single part. If you do not allocate enough extensions for the message, [TelSmsReadMessage](#) returns an error. Palm recommends allocating between 3 and 5 extensions for a message.
- You should not allocate a pointer for user extension data. If you receive user extension data, the user extension pointer will reference a block in the message data. Do not deallocate the user extension data when you release the structure.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## Telephony SMS

### Telephony SMS Functions

---

## TelSmsReadMessages

- Purpose** Retrieve a range of delivered messages from the currently selected storage area.
- Declared In** `TelephonyMgr.h`
- Prototype**  
`Err TelSmsReadMessages (UInt16 iRefnum,  
TelAppID iAppId,  
TelSmsReadMessagesType *ioParamP,  
UInt16 *ioTransIdP)`
- Parameters**
- > `iRefnum` The telephony manager library reference number.
  - > `iAppId` The telephone application attachment identifier for your application.
  - <-> `ioParamP` A pointer to a [TelSmsReadMessagesType](#) structure.  
  
On input, the `first` field of this structure specifies the index of the first message to retrieve. Message indexes are zero-based.  
  
On input the `count` field of this structure specifies the allocated size of the `messagesP` buffer. Upon return, the `count` field specifies the actual number of messages that were available, even if that many could not fit into the buffer.  
  
The `messagesP` buffer must contain pointers to [TelSmsDeliveryMessageType](#) structures that have been allocated. Each of these structures must be initialized as described for the [TelSmsReadMessage](#) function.
  - <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                               |
| <code>transId</code>    | The transaction ID of the operation.                                                                                           |
| <code>paramP</code>     | Points to the <a href="#">TelSmsReadMessagesType</a> structure passed to this function in the <code>ioParamP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsReadMessagesMessage</code>                                                                                        |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and all of the structures referenced by it remain in memory until the asynchronous call completes.

---

**Comments** If the message data or originating address string data for any of the retrieved messages is larger than the allocated size of its corresponding buffer, the data is truncated into the buffer, and this function returns the `telErrBufferSize` error.

For more information about using this function and allocating structures for its use, see the Comments description for the [TelSmsReadMessage](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

## TelSmsReadReport

**Purpose** Read a report from the currently selected storage area.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsReadReport (UInt16 iRefnum,  
TelAppID iAppId, TelSmsReportType *ioReportP,  
UInt16 *ioTransIdP)
```

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioReportP` A pointer to a [TelSmsReportType](#) structure.  
On input the `index` field of this structure contains the index of the message that you want retrieved. Message indexes are zero-based.  
On input, the `dataSize` field specifies the allocated size of the data buffer, and the `originatingAddressSize` field specifies the allocated size of the `originatingAddress` string. Upon return, each size field specifies the complete size of the data that was stored into the buffer, even the data had to be truncated to fit.
- <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                          |
| <code>transId</code>    | The transaction ID of the operation.                                                                                      |
| <code>paramP</code>     | Points to the <a href="#">TelSmsReportType</a> structure passed to this function in the <code>ioReportP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsReadReportMessage</code>                                                                                     |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments** The report data is stored into the `data` field of the [TelSmsReportType](#) structure referenced by `ioReportP`. If the complete message data is too large to fit into the allocated size of the `data` field, the report data is truncated and this function returns the `telErrBufferSize` error. The `dataSize` field of the structure is always updated to contain the actual size, in bytes, of the report data.

The originating address string is stored into the `originatingData` field of the [TelSmsReportType](#) structure referenced by `ioReportP`. If the complete string is too large to fit into the allocated size of the `originatingData` field, the string is truncated (and ends with the null terminator character) and this function returns the `telErrBufferSize` error. The `originatingAddressSize` field of the structure is always updated to contain the actual size of the string.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

## TelSmsReadReports

**Purpose** Retrieve a range of reports from the currently selected storage.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsReadReports(UInt16 iRefnum,  
TelAppID iAppId, TelSmsReadReportsType *ioParamP,  
UInt16 *ioTransIdP)
```

**Parameters**

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> iRefnum     | The telephony manager library reference number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| -> iAppId      | The telephone application attachment identifier for your application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <-> ioParamP   | <p>A pointer to a <a href="#">TelSmsReadReportsType</a> structure.</p> <p>On input, the <code>first</code> field of this structure specifies the index of the first report to retrieve. Report indexes are zero-based.</p> <p>On input the <code>count</code> field of this structure specifies the allocated size of the <code>reportsP</code> buffer. Upon return, the <code>count</code> field specifies the actual number of reports that were available, even if that many could not fit into the buffer.</p> <p>The <code>reportsP</code> buffer must contain pointers to <a href="#">TelSmsReportType</a> structures that have been allocated. Each of these structures must be initialized as described for the <a href="#">TelSmsReadReport</a> function.</p> |
| <-> ioTransIdP | Set the value of this parameter to <code>NULL</code> to cause the function to execute synchronously.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                              |
| <code>transId</code>    | The transaction ID of the operation.                                                                                          |
| <code>paramP</code>     | Points to the <a href="#">TelSmsReadReportsType</a> structure passed to this function in the <code>ioParamP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsReadReportsMessage</code>                                                                                        |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and all of the structured referenced by it remain in memory until the asynchronous call completes.

---

**Comments** If the report data or originating address string data for any of the retrieved messages is larger than the allocated size of its corresponding buffer, the data is truncated into the buffer, and this function returns the `telErrBufferSize` error. For more information, see the Comments description for the [TelSmsReadReport](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## Telephony SMS

### Telephony SMS Functions

---

## TelSmsReadSubmittedMessage

- Purpose** Read a previously submitted message that was kept on the phone after being sent.
- Declared In** `TelephonyMgr.h`
- Prototype**  
`Err TelSmsReadSubmittedMessage (UInt16 iRefnum,  
TelAppID iAppId,  
TelSmsSubmittedMessageType *ioMessageP,  
UInt16 *ioTransIdP)`
- Parameters**
- > `iRefnum` The telephony manager library reference number.
  - > `iAppId` The telephone application attachment identifier for your application.
  - <-> `ioMessageP` A pointer to a [TelSmsSubmitMessageType](#) structure that is filled in with the message.  
  
On input, the `index` field contains the index of the message that you want retrieved. Message indexes are zero-based.  
  
Upon return, the `message` field structure is filled in with the message information. You must initialize the buffer size fields of this structure prior to calling this function, including the `dataSize`, `callbackNumberSize`, `serviceCenterNumberSize`, and `destinationAddressSize` fields. Each of these fields is initialized with the allocated size of its corresponding buffer.
  - <-> `ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.  
  
If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelSmsSubmitMessageType](#) structure passed to this function in the `ioMessageP` parameter.

`functionId`       `kTelSmsSubmittedMessageMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments** The message data is stored into the `data` field of the [TelSmsSubmitMessageType](#) structure referenced by `ioMessageP`. If the complete message data is too large to fit into the allocated size of the `data` field, the end of the message data is truncated and this function returns the `telErrBufferSize` error. The `dataSize` field of the structure is always updated to contain the actual size, in bytes, of the message data.

The same strategy applies to the `callbackNumber` buffer and `callbackNumberSize` fields, the `destinationAddress` buffer and `destinationAddressSize` fields, and the `serviceCenterNumber` buffer and `serviceCenterNumberSize` fields. If the size of the data for any of the buffer fields exceeds the allocated length of the buffer, the end of the data is truncated and this function returns the `telErrBufferSize` error. Each of the size fields is always updated to contain the complete size of the data intended for the buffer.

## Telephony SMS

### Telephony SMS Functions

---

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage](#), [TelSmsSendMessage](#)

## TelSmsReadSubmittedMessages

**Purpose** Retrieve a range of submitted messages from the currently selected storage area.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelSmsReadSubmittedMessages (UInt16 iRefnum,
TelAppID iAppId,
TelSmsReadSubmittedMessagesType *ioParamP,
UInt16 *ioTransIdP)
```

**Parameters**

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> iRefnum   | The telephony manager library reference number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -> iAppId    | The telephone application attachment identifier for your application.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <-> ioParamP | A pointer to a <a href="#">TelSmsReadMessagesType</a> structure.<br><br>On input, the <code>first</code> field of this structure specifies the index of the first message to retrieve. Message indexes are zero-based.<br><br>On input, the <code>count</code> field of this structure specifies the allocated size of the <code>submittedSP</code> buffer. Upon return, the <code>count</code> field specifies the actual number of messages that were available, even if that many could not fit into the buffer. |

The `submittedSP` buffer must contain pointers to [TelSmsSubmittedMessageType](#) structures that have been allocated. Each of these structures must be initialized as described for the [TelSmsReadSubmittedMessage](#) function.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                         |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                                        |
| <code>transId</code>    | The transaction ID of the operation.                                                                                                    |
| <code>paramP</code>     | Points to the <a href="#">TelSmsReadSubmittedMessagesType</a> structure passed to this function in the <code>ioParamP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsReadSubmittedMessagesMessage</code>                                                                                        |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and all of the structured referenced by it remain in memory until the asynchronous call completes.

---

**Comments** If the message data or any of the other variable-length data for any of the retrieved messages is larger than the allocated size of its corresponding buffer, the end of the data is truncated, and this

## Telephony SMS

### Telephony SMS Functions

---

function returns the `telErrBufferSize` error. For more information, see the Comments description for the [TelSmsReadSubmittedMessage](#) function.

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsSelectStorage](#), [TelSmsSendMessage](#)

## TelSmsSelectStorage

**Purpose** Select a storage area on the phone as the current storage area.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelSmsSelectStorage(UInt16 iRefnum,  
TelAppID iAppId, UInt8 iStorageId,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- > `ioStorageId` The ID of the storage area. This must be one of the [SMS Storage ID Constants](#).
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|            |                                                                                            |
|------------|--------------------------------------------------------------------------------------------|
| returnCode | errNone upon success or an error code upon failure.                                        |
| transId    | The transaction ID of the operation.                                                       |
| paramP     | Points to the unsigned integer value passed to this function in the ioStorageId parameter. |
| functionId | kTelSmsSelectStorageMessage                                                                |

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelSmsGetAvailableStorage](#), [TelSmsGetSelectedStorage](#)

## **TelSmsSendManualAcknowledge**

**Purpose** Send a manual acknowledgment of a previously received message. Note that this function is not supported on GSM networks.

**Declared In** TelephonyMgr.h

**Prototype** Err TelSmsSendManualAcknowledge(UInt16 iRefnum, TelAppID iAppId, TelSmsManualAckType \*ioAckP, UInt16 \*ioTransIdP)

**Parameters**

|            |                                                                                                                                                               |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> iRefnum | The telephony manager library reference number.                                                                                                               |
| -> iAppId  | The telephone application attachment identifier for your application.                                                                                         |
| <-> ioAckP | A pointer to a structure of type <a href="#">TelSmsManualAckType</a> . The fields of this structure specify information about the message being acknowledged. |

## Telephony SMS

### Telephony SMS Functions

---

Upon return, the `messageId` field is filled in with the ID of the acknowledgment.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure.                                                          |
| <code>transId</code>    | The transaction ID of the operation.                                                                                      |
| <code>paramP</code>     | Points to the <a href="#">TelSmsManualAckType</a> structure passed to this function in the <code>ioAckP</code> parameter. |
| <code>functionId</code> | <code>kTelSmsSendManualAcknowledgeMessage</code>                                                                          |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## TelSmsSendMessage

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Parameters</b>          | <p>-&gt; iRefnum      The telephony manager library reference number.</p> <p>-&gt; iAppId      The telephone application attachment identifier for your application.</p> <p>&lt;-&gt; ioMessageP    A pointer to a structure of type <a href="#">TelSmsSendMessageType</a>.<br/>On input, the message field of this structure contains a <a href="#">TelSmsSubmitMessageType</a> with the message to send. You must also allocate and zero at least one <a href="#">TelSmsExtensionType</a> structure for the multi-part information.<br/>On output, the messageId field of this structure is filled in with the ID that was assigned to the sent message.</p> <p>&lt;-&gt; ioTransIdP    Set the value of this parameter to NULL to cause the function to execute synchronously.<br/>If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.</p> |
| <b>Synchronous Result</b>  | Returns <code>errNone</code> if the function was successful or returns an error code if not successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Asynchronous Result</b> | The following fields are updated in the <a href="#">TelEventType</a> event that is sent when the operation completes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Telephony SMS

### Telephony SMS Functions

---

|            |                                                                                                                    |
|------------|--------------------------------------------------------------------------------------------------------------------|
| returnCode | errNone upon success or an error code upon failure.                                                                |
| transId    | The transaction ID of the operation.                                                                               |
| paramP     | Points to the <a href="#">TelSmsSendMessageType</a> structure passed to this function in the ioMessageP parameter. |
| functionId | kTelSmsSendMessageMessage                                                                                          |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by ioMessageP remains in memory until the asynchronous call completes.

---

#### Comments

You need to make multiple calls to the [TelSmsSendMessage](#) function to send your message:

- The first call to `TelSmsSendMessage` does not actually send the message. It computes the number of parts and fills in the multi-part extension structures in the `TelSmsSendMessageType` structure. Note that you must allocate at least one extension structure, even for single-part messages.
- Subsequent calls to `TelSmsSendMessage` actually send the data.
- To send an entire message, you need to call `TelSmsSendMessage` in a loop. Terminate the loop when an error occurs, or when the `byteSend` field of the first [TelSmsExtensionType](#) structure has the same value as the `dataSize` field of the [TelSmsSendMessageType](#) structure that represents the message. For example:

---

```
while (!TelSmsSendMessage(...) &&
      msg.extensionP[0].extension.mp.byteSend != dataSend);
```

---

Before using this function, you should verify that it is available by calling the [TelIsSmsServiceAvailable](#) macro.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

# Telephony Phone Book

---

This chapter describes the phone book service set of the telephony API.

For more information about the telephony manager basic services and the different service sets, see [Chapter 68, “Telephony Basic Services.”](#)

This chapter describes:

- [Telephony Phone Book Data Structures](#)
- [Telephony Phone Book Constants](#)
- [Telephony Phone Book Functions](#)

For more information about using the telephony manager, see [Chapter 10, “Telephony Manager,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Telephony Phone Book Data Structures

This chapter describes the data structures used with the phone book service set of the telephony API.

### TelPhbEntryType

The `TelPhbEntryType` structure describes a single entry in a phone book.

```
typedef struct _TelPhbEntryType
{
    UInt16    phoneIndex;
    Char      *fullName;
    UInt8     fullNameSize;
    Char      *dialNumber;
```

## Telephony Phone Book

### Telephony Phone Book Data Structures

---

```
        UInt8    dialNumberSize;  
    } TelPhbEntryType
```

#### Field Descriptions

- > `phoneIndex`            The index of the entry in the phone's phone book. This index is always zero-based.
- The telephony manager is responsible for converting this index into the physical index in the phone, if required.
- <- `fullName`              A buffer into which the retrieved full name of the entry is stored.
- This string is stored using the local character set of the Palm™ handheld device. The telephony manager is responsible for converting the character set, if required.
- Note that if this buffer is too small to contain the entire retrieved string, the string is truncated and the function using this structure generates a `telErrBufferSize` error.
- <-> `fullNameSize`        The size of the `fullName` string.
- When the structure is used as an input parameter, this is the allocated size, in bytes, of the `fullName` buffer.
- Upon return, this is the actual size of the string, including the null terminator character. If the `fullName` buffer is too small to contain all of the retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a `telErrBufferSize` error.

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- dialNumber</code>         | <p>A buffer into which the retrieved telephone number of the entry is stored.</p> <p>Note that if this buffer is too small to contain the entire retrieved string, the string is truncated, and the function using this structure generates a <code>telErrBufferSize</code> error.</p>                                                                                                                                                                                                                                                     |
| <code>&lt;-&gt; dialNumberSize</code> | <p>The size of the <code>dialNumber</code> string.</p> <p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>dialNumber</code> buffer.</p> <p>Upon return, this is the actual size of the string, including the null terminator character. If the <code>dialNumber</code> buffer is too small to contain all of the retrieved string, this field is assigned the entire length of the string, and the function using this structure generates a <code>telErrBufferSize</code> error.</p> |

## TelPhbGetAvailablePhonebooksType

The [TelPhbGetAvailablePhonebooks](#) functions uses the `TelPhbGetAvailablePhonebooksType` structure to return a list of the phone books available on the phone.

```
typedef struct
_TelPhbGetAvailablePhonebooksType
{
    UInt16    count;
    UInt8     *phonebooksP;
} TelPhbGetAvailablePhonebooksType
```

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; count</code>   | <p>The number of entries in the array referenced by <code>phonebooksP</code>.</p> <p>When the structure is used as an input parameter, this is the allocated size, in bytes, of the <code>phonebooksP</code> buffer. Upon return, this is the actual size of the retrieved data.</p> <p>Upon return, this is the actual number of phone book IDs that could be retrieved. If the <code>phonebooksP</code> buffer is too small to contain all of the IDs, this field is assigned the actual count, and the function using this structure generates a <code>telErrBufferSize</code> error.</p> |
| <code>&lt;- phonebooksP</code> | <p>An array of retrieved phone book IDs. Each ID is one of the <a href="#">Phone Book Type Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

#### TelPhbGetEntriesType

The [TelPhbGetEntries](#) function uses the `TelPhbGetEntriesType` structure to return a list of phone entries.

```
typedef struct _TelPhbGetEntriesType
{
    UInt16          first;
    UInt16          count;
    TelPhbEntryType *entriesP;
} TelPhbGetEntriesType
```

#### Field Descriptions

|                          |                                                                                       |
|--------------------------|---------------------------------------------------------------------------------------|
| <code>-&gt; first</code> | <p>The index of the first entry in the array referenced by <code>entriesP</code>.</p> |
|--------------------------|---------------------------------------------------------------------------------------|

|                              |                                                                                                                                                                                    |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; count</code> | When the structure is used as an input parameter, this is number of entries that you want retrieved.<br><br>Upon return, this is the actual number of entries that were retrieved. |
| <code>&lt;- entriesP</code>  | An array of pointers to retrieved <a href="#">TelPhbEntryType</a> structures.                                                                                                      |

## TelPhbGetEntryCountType

The [TelPhbGetEntryCount](#) function uses the `TelPhbGetEntryCountType` structure to return information about the entries in the currently selected phone book.

```
typedef struct _TelPhbGetEntryCountType
{
    UInt16      slots;
    UInt16      count;
} TelPhbGetEntryCountType
```

### Field Descriptions

|                          |                                                              |
|--------------------------|--------------------------------------------------------------|
| <code>&lt;- slots</code> | The total number of entry slots available in the phone book. |
| <code>c count</code>     | The number of filled slots in the phone book.                |

## TelPhbGetEntryMaxSizesType

The [TelPhbGetEntryMaxSizes](#) function uses the `TelPhbGetEntryMaxSizesType` structure to return size information about the entries in the currently selected phone book.

```
typedef struct _TelPhbGetEntryMaxSizeType
{
    UInt8      fullNameMaxSize;
    UInt8      dialNumberMaxSize;
} TelPhbGetEntryMaxSizesType
```

## Telephony Phone Book

### Telephony Phone Book Constants

---

#### Field Descriptions

- <- `fullNameMaxSize` The largest size of any `fullName` field in the phone book.
- <- `dialNumberMaxSize` The largest size of any `dialNumber` field in the phone book.

## Telephony Phone Book Constants

This section describes the constants used with the phone book service set of the telephony API.

### Phone Book Type Constants

The phone book type constants specify the type of phone book that is currently selected.

---

| Constant                                 | Value | Description                                                            |
|------------------------------------------|-------|------------------------------------------------------------------------|
| <code>kTelPhbFixedPhonebook</code>       | 0     | The phone book stored on the phone.                                    |
| <code>kTelPhbSimPhonebook</code>         | 1     | The phone book stored on the SIM card.                                 |
| <code>kTelPhbPhonePhonebook</code>       | 2     | The phone book stored on the phone.                                    |
| <code>kTelPhbLastDialedPhonebook</code>  | 3     | The phone book from which a telephone number was most recently dialed. |
| <code>kTelPhbSimAndPhonePhonebook</code> | 4     | The combined phone and SIM card phone books.                           |

| Constant                 | Value | Description                                                                                                                                                                                                 |
|--------------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kTelPhbAdaptorPhonebook  | 5     | The phone book stored on the telephone adaptor.                                                                                                                                                             |
| kTelPhbFirstOemPhonebook | 6     | The ID of the first OEM phone book.<br><br>You can specify additional OEM phone books by incrementing this value; for example, the second OEM phone book is specified as:<br>kTelPhbFirstOemPhonebook<br>+1 |

---

## Telephony Phone Book Functions

This section describes the functions used with the phone book service set of the telephony API.

### TelPhbAddEntry

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                                 |           |                                                                       |            |                                                                                                   |                |                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|-------------------------------------------------|-----------|-----------------------------------------------------------------------|------------|---------------------------------------------------------------------------------------------------|----------------|-----------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Add or replace an entry in the currently selected phone book.                                                                                                                                                                                                                                                                                                                                                                                                                                     |            |                                                 |           |                                                                       |            |                                                                                                   |                |                                                                                         |
| <b>Declared In</b> | TelephonyMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                                 |           |                                                                       |            |                                                                                                   |                |                                                                                         |
| <b>Prototype</b>   | <pre>Err TelPhbAddEntry(UInt16 iRefnum,<br/>TelAppID iAppId, TelPhbEntryType *iEntryP,<br/>UInt16 *ioTransIdP)</pre>                                                                                                                                                                                                                                                                                                                                                                              |            |                                                 |           |                                                                       |            |                                                                                                   |                |                                                                                         |

## Telephony Phone Book

*Telephony Phone Book Functions*

---

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelPhbEntryType](#) structure passed to this function in the `iEntryP` parameter.

`functionId`      `kTelPhbAddEntryMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `iEntryP` remains in memory until the asynchronous call completes.

---

**Comments** The `phoneIndex` field of the [TelPhbEntryType](#) structure referenced by `iEntryP` specifies the index at which to write the entry.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbDeleteEntry](#), [TelPhbSelectPhonebook](#)

## **TelPhbGetAvailablePhonebooks**

- Purpose** Retrieve the list of all phone books available on the phone.
- Declared In** `TelephonyMgr.h`
- Prototype**  
`Err TelPhbGetAvailablePhonebooks (UInt16 iRefnum,  
TelAppID iAppId,  
TelPhbGetAvailablePhonebooksType *ioParamP,  
UInt16 *ioTransIdP)`
- Parameters**
- |                                 |                                                                                                                                                                                                                                                                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; iRefnum</code>      | The telephony manager library reference number.                                                                                                                                                                                                                                                                                                                                                     |
| <code>-&gt; iAppId</code>       | The telephone application attachment identifier for your application.                                                                                                                                                                                                                                                                                                                               |
| <code>&lt;-&gt; ioParamP</code> | A pointer to a <a href="#">TelPhbGetAvailablePhonebooksType</a> structure that lists the available phone books.<br><br>On input, the <code>count</code> field of this structure specifies the allocated size of the <code>phonebookP</code> buffer. Upon return, the <code>count</code> field specifies the actual number of entries retrieved, even if they were truncated to fit into the buffer. |

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result**

Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result**

The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelPhbGetAvailablePhonebooksType](#) structure passed to this function in the `iEntryP` parameter.

`functionId`      `kTelPhbGetAvailablePhonebooksMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` remains in memory until the asynchronous call completes.

---

**Comments**

The phone book IDs are stored into the `phonebookP` field of the [TelPhbGetAvailablePhonebooksType](#) structure referenced by `ioParamP`. If the `phonebookP` buffer is too small to contain all of the IDs, the information is truncated and this function returns the `telErrBufferSize` error. The `count` field of the structure is always updated to contain the actual number of entries that were retrieved.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbSelectPhonebook](#)

## TelPhbGetEntries

**Purpose** Retrieve a range of entries from the currently selected phone book.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelPhbGetEntries(UInt16 iRefnum,  
TelAppID iAppId, TelPhbGetEntriesType *ioParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <-> `ioParamP` A pointer to a [TelPhbGetEntriesType](#) structure that is updated with the phone book entry information. The first entry retrieved is specified in the `first` field of this structure, which is zero-based; the number of entries retrieved is specified by the `count` field. Thus, the last entry retrieved is specified by:  

```
ioParamP->first +  
ioParamP->count - 1
```

Upon return, the `count` field of the structure is the number of entries that were actually retrieved.  
The `entriesP` field of this structure is a buffer that you allocate to contain the required number of pointers. Each pointer references a [TelPhbEntryType](#) structure that you must also preallocate.

On input, the `fullNameSize` and `dialNumberSize` fields of this structure specify the allocated sizes of the `fullName` and `dialNumber` buffers. Upon return, the `fullNameSize` and `dialNumberSize` fields specify the actual sizes of the buffers, even if a string was truncated to fit into the buffer.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|                         |                                                                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <code>returnCode</code> | <code>errNone</code> upon success or an error code upon failure                                                                |
| <code>transId</code>    | The transaction ID of the operation.                                                                                           |
| <code>paramP</code>     | Points to the <a href="#">TelPhbGetEntriesType</a> structure passed to this function in the <code>ioEntriesP</code> parameter. |
| <code>functionId</code> | <code>kTelPhbGetEntriesMessage</code>                                                                                          |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by `ioParamP` and any structures that it references remain in memory until the asynchronous call completes.

---

**Comments** The phone book information is stored into the [TelPhbEntryType](#) structures that you preallocate and refer to in the `entriesP` field of

the [TelPhbGetEntriesType](#) referenced by the `ioParamP` parameter.

If any buffer in any of the `TelPhbEntryType` structures is too small, the string intended for that buffer is truncated, and this function returns the `telErrBufferSize` error. In any case, the `fullNameSize` and `dialNumberSize` fields of each `TelPhbEntryType` structure contain the actual size of their respective strings.

If any entries in the specified range are empty, the entry is not retrieved, and the `count` value in the structure is updated.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbGetEntry](#), [TelPhbSelectPhonebook](#)

## TelPhbGetEntry

**Purpose** Retrieve one entry from the currently selected phone book.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelPhbGetEntry(UInt16 iRefnum,
TelAppID iAppId, TelPhbEntryType *ioEntryP,
UInt16 *ioTransIdP)
```

**Parameters**

|                           |                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------------------------------------------|
| -> <code>iRefnum</code>   | The telephony manager library reference number.                                                                 |
| -> <code>iAppId</code>    | The telephone application attachment identifier for your application.                                           |
| <-> <code>ioEntryP</code> | A pointer to a <a href="#">TelPhbEntryType</a> structure that is updated with the phone book entry information. |

On input, the `fullNameSize` and `dialNumberSize` fields of this structure specify the allocated sizes of the `fullName` and `dialNumber` buffers. Upon return, the `fullNameSize` and `dialNumberSize` fields specify the actual sizes of the buffers, even if a string was truncated to fit into the buffer.

`<-> ioTransIdP` Set the value of this parameter to `NULL` to cause the function to execute synchronously.

If this parameter is not `NULL`, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode`      `errNone` upon success or an error code upon failure.

`transId`          The transaction ID of the operation.

`paramP`           Points to the [TelPhbEntryType](#) structure passed to this function in the `ioEntryP` parameter.

`functionId`      `kTelPhbGetEntryMessage`

**Comments** The phone book information is stored into the [TelPhbEntryType](#) that you preallocate. If either buffer in the structure is too small, the string intended for that buffer is truncated, and this function returns the `telErrBufferSize` error. In any case, the `fullNameSize` and `dialNumberSize` fields of the structure contain the actual size of their respective strings.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbGetEntries](#), [TelPhbSelectPhonebook](#)

## TelPhbGetEntryCount

**Purpose** Retrieve the total number of entries, and the number of filled entries in the currently selected phone book.

**Declared In** `TelephonyMgr.h`

**Prototype**

```
Err TelPhbGetEntryCount (UInt16 iRefnum,  
TelAppID iAppId,  
TelPhbGetEntryCountType *oParamP,  
UInt16 *ioTransIdP)
```

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <- `oParamP` A pointer to a [TelPhbGetEntryCountType](#) structure that is updated with information about the number of entries in the phone book.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

|            |                                                                                                                   |
|------------|-------------------------------------------------------------------------------------------------------------------|
| returnCode | errNone upon success or an error code upon failure.                                                               |
| transId    | The transaction ID of the operation.                                                                              |
| paramP     | Points to the <a href="#">TelPhbGetEntryCountType</a> structure passed to this function in the oParamP parameter. |
| functionId | kTelPhbGetEntryCountMessage                                                                                       |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by oParamP remains in memory until the asynchronous call completes.

---

**Comments** The total number of slots and the number of filled slots in the currently selected phone book are stored in the [TelPhbGetEntryCountType](#) structure referenced by oParamP. Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbSelectPhonebook](#)

## TelPhbGetEntryMaxSizes

**Purpose** Retrieves the maximum buffer sizes of any entries in the currently selected phone book.

**Declared In** `TelephonyMgr.h`

**Prototype** `Err TelPhbGetEntryMaxSizes(UInt16 iRefnum,  
TelAppID iAppId,  
TelPhbGetEntryMaxSizesType *oParamP,  
UInt16 *ioTransIdP)`

**Parameters**

- > `iRefnum` The telephony manager library reference number.
- > `iAppId` The telephone application attachment identifier for your application.
- <- `oParamP` A pointer to a [TelPhbGetEntryMaxSizesType](#) structure that is updated with information about the maximum buffer sizes of entries in the phone book.
- <-> `ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously.  
  
If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

|            |                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------|
| paramP     | Points to the <a href="#">TelPhbGetEntryMaxSizesType</a> structure passed to this function in the oParamP parameter. |
| functionId | kTelPhbGetEntryMaxSizesMessage                                                                                       |

---

**WARNING!** When using this function asynchronously, you must ensure that the structure referenced by oParamP remains in memory until the asynchronous call completes.

---

**Comments** The maximum size of any full name entry and the maximum size of any telephone number entry in the currently selected phone book are stored in the [TelPhbGetEntryMaxSizesType](#) structure referenced by oParamP.

Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbGetEntries](#), [TelPhbGetEntry](#)

## TelPhbGetSelectedPhonebook

**Purpose** Retrieve the ID of the currently selected phone book.

**Declared In** TelephonyMgr.h

**Prototype** Err TelPhbGetSelectedPhonebook (UInt16 iRefnum, TelAppID iAppId, UInt8 \*oPhbIdP, UInt16 \*ioTransIdP)

**Parameters**

|            |                                                                       |
|------------|-----------------------------------------------------------------------|
| -> iRefnum | The telephony manager library reference number.                       |
| -> iAppId  | The telephone application attachment identifier for your application. |

## Telephony Phone Book

### Telephony Phone Book Functions

---

`<- oPhbIdP` A pointer to an unsigned byte value. Upon return, this is filled in with the identifier of the currently selected phone book. The identifier is one of the [Phone Book Type Constants](#).

`<-> ioTransIdP` Set the value of this parameter to NULL to cause the function to execute synchronously. If this parameter is not NULL, the call executes asynchronously. Upon return from this function, this points to the transaction identifier associated with the asynchronous operation.

**Synchronous Result** Returns `errNone` if the function was successful or returns an error code if not successful.

**Asynchronous Result** The following fields are updated in the [TelEventType](#) event that is sent when the operation completes:

`returnCode` `errNone` upon success or an error code upon failure.

`transId` The transaction ID of the operation.

`paramP` Points to the unsigned integer value passed to this function in the `oPhbIdP` parameter.

`functionId` `kTelPhbGetSelectedPhonebookMessage`

---

**WARNING!** When using this function asynchronously, you must ensure that the value referenced by `oPhbIdP` remains in memory until the asynchronous call completes.

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## Telephony Phone Book

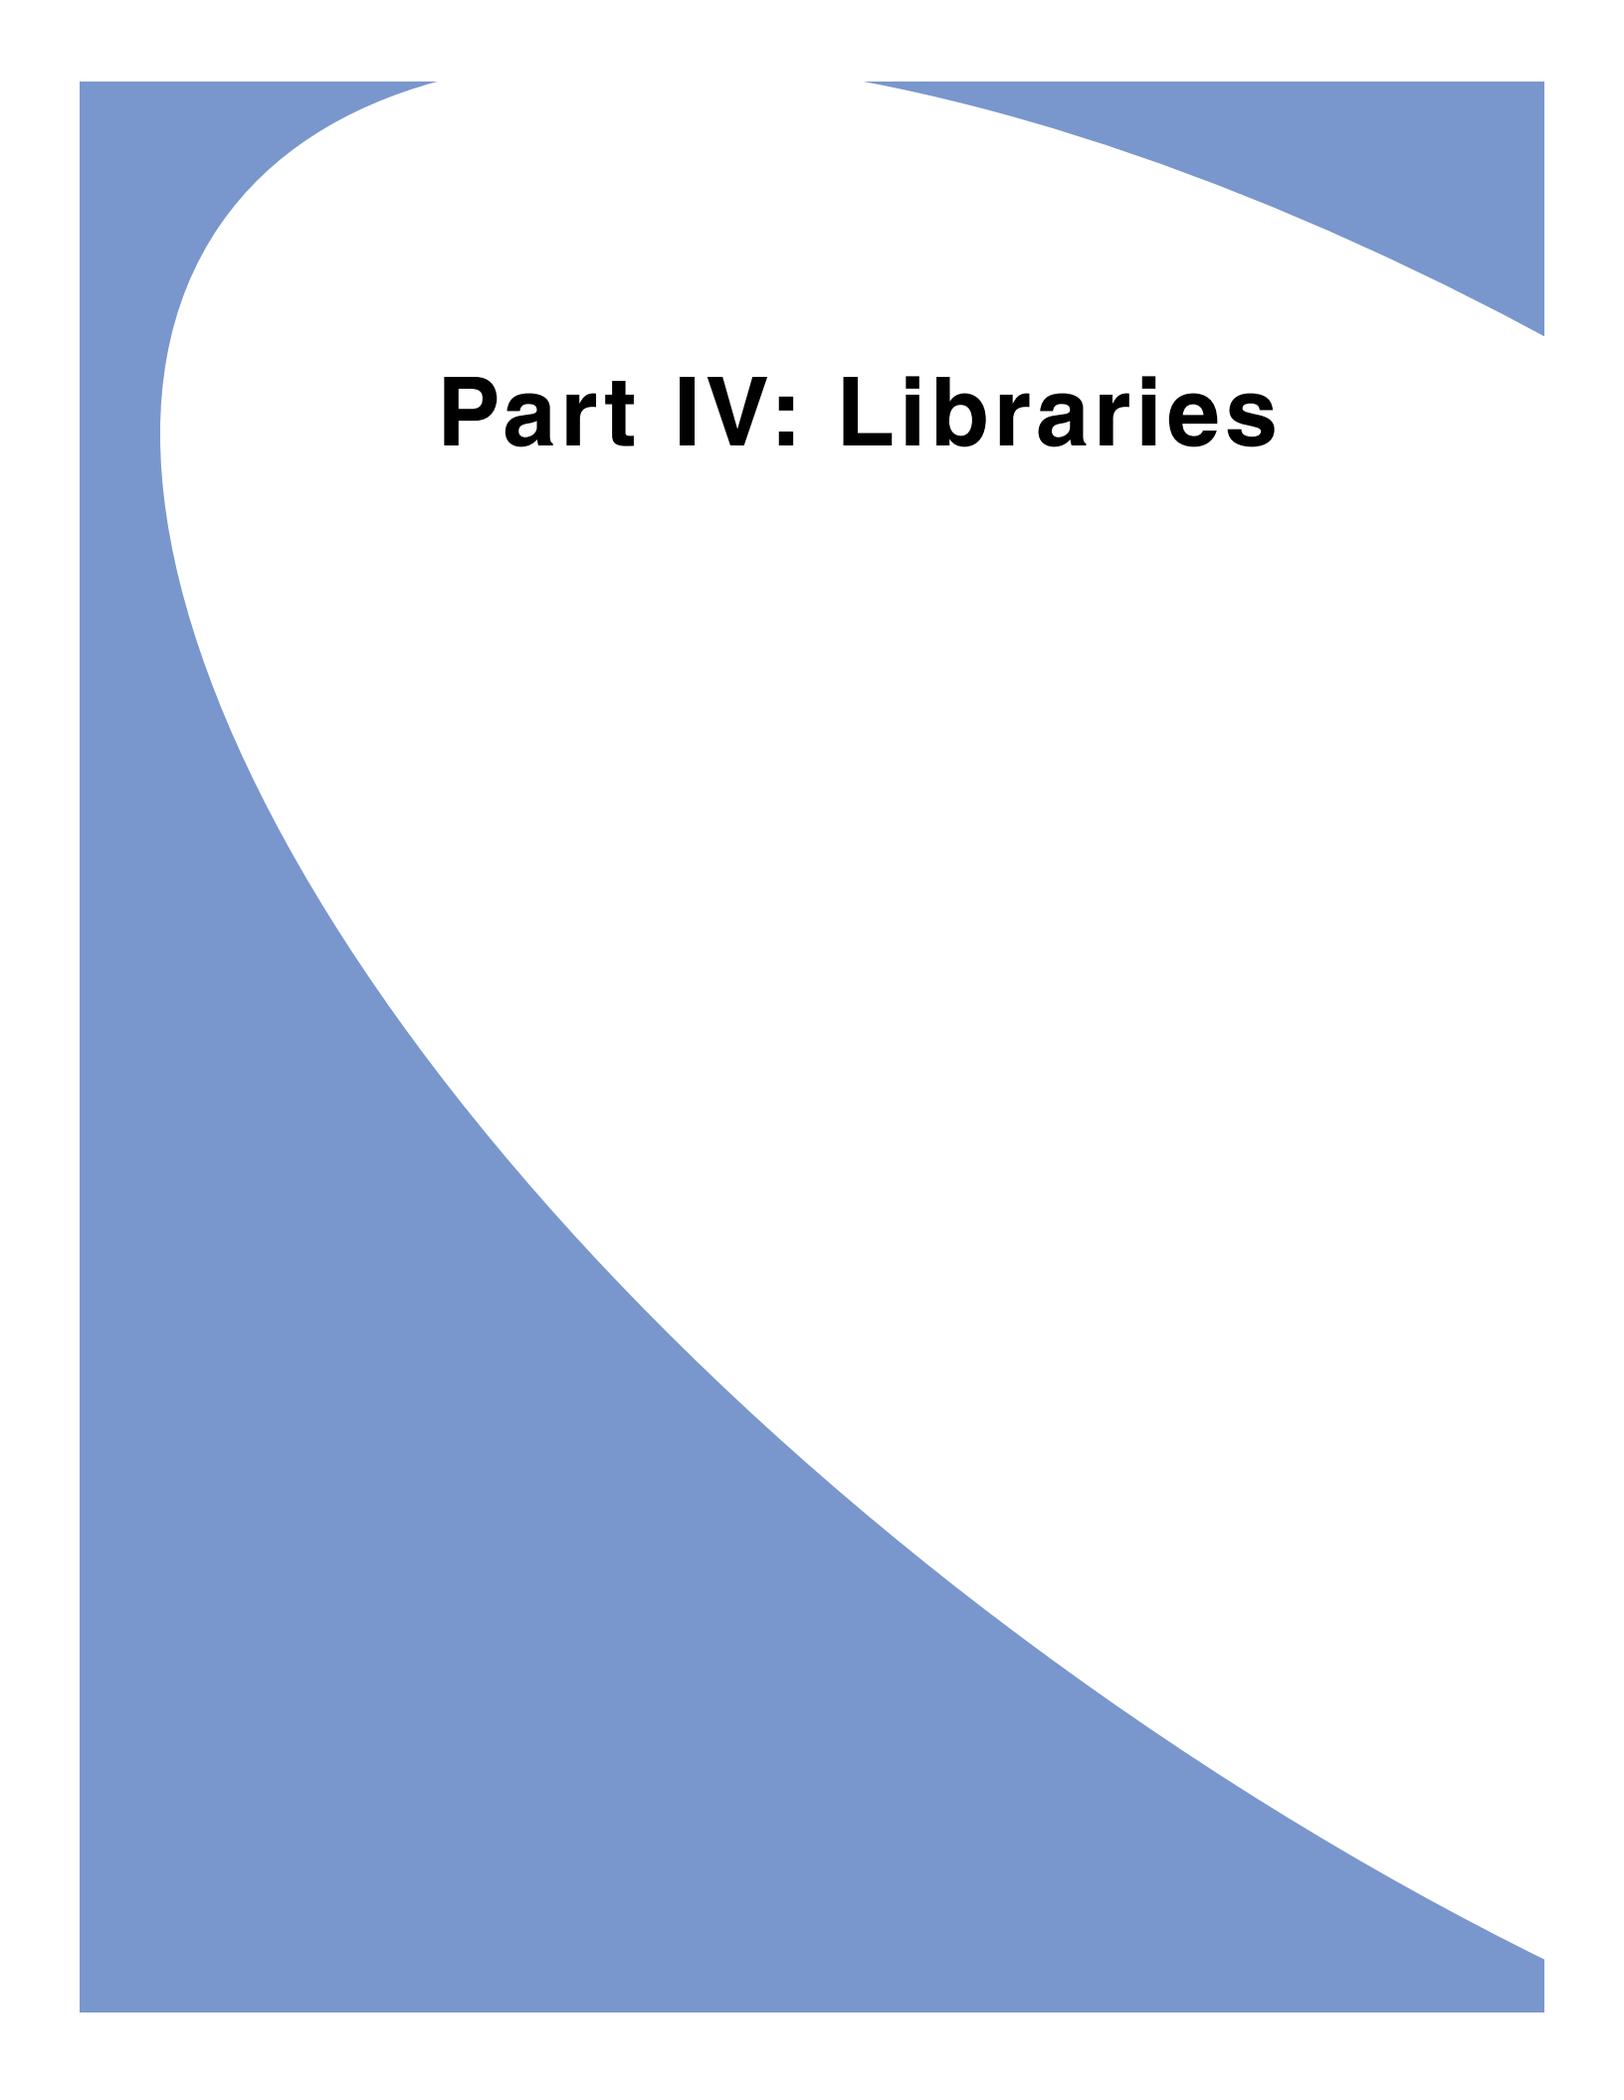

*Telephony Phone Book Functions*

---

**Comments** Before using this function, you should verify that it is available by calling the [TelIsPhbServiceAvailable](#) macro.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [TelPhbGetAvailablePhonebooks](#),  
[TelPhbGetSelectedPhonebook](#)

# **Part IV: Libraries**

# Internet Library

---

This chapter provides reference material for the Internet library API:

- [Internet Library Data Structures](#)
- [Internet Library Constants](#)
- [Internet Library Functions](#)

The header file `INetMgr.h` declares the Internet library API. For more information on the Internet library, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

---

**NOTE:** The information in this chapter applies only to version 3.2 or later of the Palm OS® on Palm VII® devices. These features are implemented only if the [Wireless Internet Feature Set](#) is present.

---

---

**WARNING!** In future OS versions, PalmSource, Inc. does not intend to support or provide backward compatibility for the Internet library API documented in this chapter.

---

## Internet Library Data Structures

### INetCompressionTypeEnum

The `INetCompressionTypeEnum` enum indicates the type of compression used for data exchanged via a socket. One of these enumerated types is set as the value of the [inetSockSettingCompressionTypeID](#) socket setting (a read-only setting).

## Internet Library

### Internet Library Data Structures

---

---

```
typedef enum {
inetCompressionTypeNone = 0,
inetCompressionTypeBitPacked,
inetCompressionTypeLZ77
} INetCompressionTypeEnum;
```

---

#### Value Descriptions

|                                           |                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <code>inetCompressionTypeNone</code>      | No compression.                                                                                                |
| <code>inetCompressionTypeBitPacked</code> | Custom 5-bit compression scheme. This is typically used for data sent from the Palm Web Clipping Proxy server. |
| <code>inetCompressionTypeLZ77</code>      | Not used; reserved for future use.                                                                             |

## INetConfigNameType

The `INetConfigNameType` structure holds the name of an Internet library network **configuration**. A configuration is a set of specific values for the Internet library settings. The Internet library defines a set of built-in configuration aliases for common network setups. These aliases point to configurations instead of holding the actual values themselves. You can use an alias anywhere in the API you would use a configuration. System-defined configuration aliases are listed in “[Configuration Aliases](#)” on page 1850.

This structure is used in the functions [INetLibConfigIndexFromName](#), [INetLibConfigRename](#), and [INetLibConfigSaveAs](#).

---

```
#define inetConfigNameSize 32;

typedef struct {
Char name[inetConfigNameSize]; // name of configuration
} INetConfigNameType, *INetConfigNamePtr;
```

---

#### Field Description

|                   |                                             |
|-------------------|---------------------------------------------|
| <code>name</code> | A configuration name (up to 32 characters). |
|-------------------|---------------------------------------------|

## INetContentTypeEnum

The `INetContentTypeEnum` enum specifies the type of content to be exchanged via a socket. One of these enumerated types is set as the value of the [inetSockSettingContentTypeID](#) socket setting (a read-only setting).

---

```
typedef enum {
inetContentTypeTextPlain = 0,
inetContentTypeTextHTML,
inetContentTypeImageGIF,
inetContentTypeImageJPEG,
inetContentTypeApplicationCML,
inetContentTypeImagePalmOS,
inetContentTypeOther
} INetContentTypeEnum;
```

---

### Value Descriptions

|                                            |                                                                                      |
|--------------------------------------------|--------------------------------------------------------------------------------------|
| <code>inetContentTypeTextPlain</code>      | Not used                                                                             |
| <code>inetContentTypeTextHTML</code>       | Not used                                                                             |
| <code>inetContentTypeImageGIF</code>       | Not used                                                                             |
| <code>inetContentTypeImageJPEG</code>      | Not used                                                                             |
| <code>inetContentTypeApplicationCML</code> | Compressed HTML content (format used by the Palm Web Clipping Proxy server and PQAs) |
| <code>inetContentTypeImagePalmOS</code>    | Palm OS <sup>®</sup> bitmap                                                          |
| <code>inetContentTypeOther</code>          | Some undefined content type                                                          |

## INetHTTPAttrEnum

The `INetHTTPAttrEnum` enum specifies HTTP request and response attributes that are set by [INetLibSockHTTPAttrSet](#) and returned by [INetLibSockHTTPAttrGet](#).

## Internet Library

### Internet Library Data Structures

---

```
typedef enum {  
  
    //-----  
    // Request only attributes  
    //-----  
    // The following are ignored unless going through a CTP proxy  
    inetHTTPAttrWhichPart, // (W) UInt32 (0 -> N)  
    inetHTTPAttrIncHTTP, // (W) UInt32 (Boolean) only applicable  
        // when inetHTTPAttrConvAlgorithm set to ctpConvNone  
    inetHTTPAttrCheckMailHi, // (W) UInt32  
    inetHTTPAttrCheckMailLo, // (W) UInt32  
    inetHTTPAttrReqContentVersion, // (W) UInt32, desired content  
        // version. Represented as 2 low bytes. Lowest  
byte is  
        // minor version, next higher byte is major  
version.  
    //-----  
    ---  
    // Response only attributes  
    //-----  
    ---  
    // Server response info  
    inetHTTPAttrRspSize, // (R) UInt32, entire HTTP Response size  
        // including header and data  
    inetHTTPAttrResult, // (R) UInt32 (ctpErrXXX when using CTP  
Proxy)  
    inetHTTPAttrErrDetail, // (R) UInt32 (server/proxy err code  
when  
        // using CTP Proxy)  
    inetHTTPAttrReason, // (R) Char[]  
    // Returned entity attributes  
    inetHTTPAttrContentLength, // (R) UInt32  
    inetHTTPAttrContentLengthUncompressed, // (R) UInt32 (in  
bytes)  
    inetHTTPAttrContentLengthUntruncated, //(R) UInt32  
    inetHTTPAttrContentVersion, // (R) UInt32, actual content  
version.  
        // Represented as 2 low bytes. Lowest byte is minor  
        // version, next higher byte is major version.  
    inetHTTPAttrContentCacheID, // (R) UInt32, cacheID for this  
item  
    inetHTTPAttrReqSize // (R) UInt32 size of request sent  
} INetHTTPAttrEnum;
```

---

### Value Descriptions

|                                                    |                                                                                                                                                                                                                             |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetHTTPAttrWhichPart</code>                 | An index to the part of the response data desired, if the response data is partitioned into chunks. Write-only.                                                                                                             |
| <code>inetHTTPAttrIncHTTP</code>                   | A Boolean that, if set, causes HTTP header data to be included as part of the content when retrieving raw data. Applicable only when <code>inetSettingConvAlgorithm</code> is set to <code>ctpConvNone</code> . Write-only. |
| <code>inetHTTPAttrCheckMailHi</code>               | High-order byte of ID for checking mail. Write-only.                                                                                                                                                                        |
| <code>inetHTTPAttrCheckMailLo</code>               | Low-order byte of ID for checking mail. Write-only.                                                                                                                                                                         |
| <code>inetHTTPAttrReqContentVersion</code>         | Desired content version. Represented as 2 low bytes. Lowest byte is minor version, next higher byte is major version. Write-only.                                                                                           |
| <code>inetHTTPAttrRspSize</code>                   | Size of entire HTTP (header and data). Read-only.                                                                                                                                                                           |
| <code>inetHTTPAttrResult</code>                    | Transport protocol error code. Read-only.                                                                                                                                                                                   |
| <code>inetHTTPAttrErrDetail</code>                 | Server/proxy error code when using the Palm Web Clipping Proxy server. Read-only.                                                                                                                                           |
| <code>inetHTTPAttrReason</code>                    | Transport protocol error message. Read-only.                                                                                                                                                                                |
| <code>inetHTTPAttrContentLength</code>             | Size of response data. Read-only.                                                                                                                                                                                           |
| <code>inetHTTPAttrContentLengthUncompressed</code> | Size of uncompressed response data. Read-only.                                                                                                                                                                              |
| <code>inetHTTPAttrContentLengthUntruncated</code>  | Total size of response data (it may have been truncated to less than this). Read-only.                                                                                                                                      |

## Internet Library

### Internet Library Data Structures

---

|                                         |                                                                                                                                 |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <code>inetHTTPAttrContentVersion</code> | Actual content version. Represented as 2 low bytes. Lowest byte is minor version, next higher byte is major version. Read-only. |
| <code>inetHTTPAttrContentCacheID</code> | Cache ID for this item. Read-only.                                                                                              |
| <code>inetHTTPAttrReqSize</code>        | Size of request sent. Read-only.                                                                                                |

## INetSchemeEnum

The `INetSchemeEnum` enum specifies a protocol (`http`, `https`, etc.) used by a socket. Specify one of these enumerated types for the `INetSockSettingScheme` socket setting and for the `scheme` parameter to the [INetLibSockOpen](#) call.

---

```
typedef enum {
inetSchemeUnknown = -1,
inetSchemeDefault = 0,    // not used

inetSchemeHTTP, // http:
inetSchemeHTTPS, // https:
inetSchemeFTP, // ftp:
inetSchemeGopher, // gopher:
inetSchemeFile, // file:
inetSchemeNews, // news:
inetSchemeMailTo, // mailto:
inetSchemePalm, // palm:
inetSchemePalmCall, // palmcall:
inetSchemeMail, // not applicable to URLs, but used
                    // for the INetLibSockOpen call when
                    // creating a socket for mail IO
inetSchemeMac, // mac: - Mac file system HTML

inetSchemeFirst = inetSchemeHTTP, // first one
inetSchemeLast = inetSchemeMail // last one
} INetSchemeEnum;
```

---

### Value Descriptions

|                              |                                                   |
|------------------------------|---------------------------------------------------|
| <code>inetSchemeHTTP</code>  | Use the HTTP protocol.                            |
| <code>inetSchemeHTTPS</code> | Use the HTTPS protocol (for a secure connection). |

|                                 |                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSchemeFTP</code>      | Use the FTP protocol. Not implemented.                                                                                                                                                                                                                                                                                                                                |
| <code>inetSchemeGopher</code>   | Use the Gopher protocol. Not implemented.                                                                                                                                                                                                                                                                                                                             |
| <code>inetSchemeFile</code>     | Launch local PQA file                                                                                                                                                                                                                                                                                                                                                 |
| <code>inetSchemeNews</code>     | Use the News protocol. Not implemented.                                                                                                                                                                                                                                                                                                                               |
| <code>inetSchemeMailTo</code>   | Launch the local messaging application, passing a “to” address.                                                                                                                                                                                                                                                                                                       |
| <code>inetSchemePalm</code>     | Launches a local application database. The URL is expected to be in the form <code>cccc.tttt</code> , where <code>cccc</code> is a four character creator name and <code>tttt</code> is a four character database type. This pair of strings is used to identify an application database to receive the launch message via a call to <a href="#">SysUIAppSwitch</a> . |
| <code>inetSchemePalmCall</code> | Launches a local application database. The URL is expected to be in the form <code>cccc.tttt</code> , where <code>cccc</code> is a four character creator name and <code>tttt</code> is a four character database type. This pair of strings is used to identify an application database to receive the launch message via a call to <a href="#">SysAppLaunch</a> .   |
| <code>inetSchemeMail</code>     | Creates a socket for mail I/O.                                                                                                                                                                                                                                                                                                                                        |
| <code>inetSchemeMac</code>      | Handles opening Mac OS file system HTML URLs. For use by the Simulator only.                                                                                                                                                                                                                                                                                          |

## INetSettingEnum

The `INetSettingEnum` enum specifies a setting to be returned or set by the [INetLibSettingGet](#) or [INetLibSettingSet](#) calls.

---

```
typedef enum {
inetSettingCacheSize, // (RW) UInt32, max size of cache
inetSettingCacheRef, // (R) DmOpenRef, ref of cache DB
inetSettingNetLibConfig, // (RW) UInt32, NetLib config to use
inetSettingRadioID, // (R) UInt32[2], the 64-bit radio ID
inetSettingBaseStationID, // (R) UInt32, the radio base
station Id
inetSettingMaxRspSize, // (W) UInt32 (in bytes)
inetSettingConvAlgorithm, // (W) UInt32 (CTPConvEnum)
inetSettingContentWidth, // (W) UInt32 (in pixels)
```

## Internet Library

### Internet Library Data Structures

---

```
inetSettingContentVersion, // (W) UInt32, content version
(encoder
                                // version)
inetSettingNoPersonalInfo, // (RW) UInt32, send no deviceID/
zipcode
inetSettingUserName,
inetSettingLast
} INetSettingEnum;
```

---

### Value Descriptions

|                                       |                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSettingCacheSize</code>     | Maximum size of cache (in bytes).                                                                                                                                                                                                                                                                                                                                        |
| <code>inetSettingCacheRef</code>      | <code>DmOpenRef</code> , reference to cache database. Read-only.                                                                                                                                                                                                                                                                                                         |
| <code>inetSettingNetLibConfig</code>  | The index of the net library network configuration to use. This value is saved as part of the preferences for each Internet library configuration. A value of 0 means to use the current configuration.                                                                                                                                                                  |
| <code>inetSettingRadioID</code>       | 64-bit radio ID. Read-only. Used for wireless connections only.                                                                                                                                                                                                                                                                                                          |
| <code>inetSettingBaseStationID</code> | Radio base station ID. Read-only. Used for wireless connections only.                                                                                                                                                                                                                                                                                                    |
| <code>inetSettingMaxRspSize</code>    | Maximum response size, in bytes. The default is 1024 bytes. Write-only.                                                                                                                                                                                                                                                                                                  |
| <code>inetSettingConvAlgorithm</code> | Content conversion desired. Write-only. Possible values include:<br><code>ctpConvCML</code> (use 5-bit compression scheme),<br><code>ctpConvCML8Bit</code> (use 5-bit compression scheme, but in 8-bit form for debugging),<br><code>ctpConvCMLLZ77</code> (use LZ77 compression scheme),<br><code>ctpConvNone</code> (no conversion; data is returned in native format) |
| <code>inetSettingContentWidth</code>  | Width of the display for content. The default setting is 160 (pixels). Write-only.                                                                                                                                                                                                                                                                                       |

|                                        |                                                                                                                                                                                                                                                                                                              |
|----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSettingContentVersion</code> | Content version (encoder version). Write-only. This setting is used to let the server know what encoder version it should use to encode content sent to the Palm client. Normally you don't need to set this value as it is initialized by <code>INetLibOpen</code> . The default encoder version is 0x8001. |
| <code>inetSettingNoPersonalInfo</code> | Send no device ID or zipcode information to the proxy server. This value is saved as part of the preferences for each Internet library configuration.                                                                                                                                                        |
| <code>inetSettingUserName</code>       | Not applicable.                                                                                                                                                                                                                                                                                              |

## **INetSockSettingEnum**

The `INetSockSettingEnum` enum specifies a socket setting to be returned or set by the [INetLibSockSettingGet](#) or [INetLibSockSettingSet](#) calls.

---

```
typedef enum {
inetSockSettingScheme, // (R) UInt32, INetSchemeEnum
inetSockSettingSockContext, // (RW) UInt32,
inetSockSettingCompressionType, // (R) Char[]
inetSockSettingCompressionTypeID, // (R) UInt32
//
(INetCompressionTypeEnum)
inetSockSettingContentType, // (R) Char[]
inetSockSettingContentTypeID, // (R) UInt32
(INetContentTypeEnum)
inetSockSettingData, // (R) UInt32, pointer to data
inetSockSettingDataHandle, // (R) UInt32, handle to data
inetSockSettingDataOffset, // (R) UInt32, offset to data from
handle
inetSockSettingTitle, // (W) Char[]
inetSockSettingURL, // (R) Char[]
inetSockSettingIndexURL, // (RW) Char[]
inetSockSettingFlags, // (RW) UInt16, one or more of
// inetOpenURLFlagXXX flags
inetSockSettingReadTimeout, // (RW) UInt32, read timeout in
ticks
inetSockSettingContentVersion, // (R) UInt32, content version
number
inetSockSettingLast
} INetSockSettingEnum;
```

---

#### Value Descriptions

|                                               |                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSockSettingScheme</code>            | Requested scheme; one of the <a href="#">INetSchemeEnum</a> values. Read-only.                                                                                                                                                                                                                                      |
| <code>inetSockSettingSockContext</code>       | Not used.                                                                                                                                                                                                                                                                                                           |
| <code>inetSockSettingCompressionType</code>   | Name of requested compression type. Read-only.                                                                                                                                                                                                                                                                      |
| <code>inetSockSettingCompressionTypeID</code> | Requested compression type; one of the <a href="#">INetCompressionTypeEnum</a> values. Read-only.                                                                                                                                                                                                                   |
| <code>inetSockSettingContentType</code>       | String containing the MIME type of the content. Used only on received raw data. Read-only.                                                                                                                                                                                                                          |
| <code>inetSockSettingContentTypeID</code>     | Content type of socket data; one of the <a href="#">INetContentTypeEnum</a> values. Read-only.                                                                                                                                                                                                                      |
| <code>inetSockSettingData</code>              | Pointer to socket data. Read-only.                                                                                                                                                                                                                                                                                  |
| <code>inetSockSettingDataHandle</code>        | Handle to socket data. Read-only.                                                                                                                                                                                                                                                                                   |
| <code>inetSockSettingDataOffset</code>        | Offset to socket data from handle. Read-only.                                                                                                                                                                                                                                                                       |
| <code>inetSockSettingTitle</code>             | Web page title. This value is written to the cache (and the Web Clipping Application Viewer uses it later in a history list of cache entries). Write-only.                                                                                                                                                          |
| <code>inetSockSettingURL</code>               | URL of requested data. Read-only.                                                                                                                                                                                                                                                                                   |
| <code>inetSockSettingIndexURL</code>          | Index (or master) URL of requested data (for cache indexing). This is the topmost web page in a group of hierarchical pages; it serves to group the pages together and to filter cache list results. The Web Clipping Application Viewer sets this to the URL of the active PQA, for all pages linked from the PQA. |

|                                            |                                                                                                                                                                                                                                                             |
|--------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetSockSettingFlags</code>          | URL request flags; one or more of <code>inetOpenURLFlag...</code> flags (see <a href="#">URL Open Constants</a> ).                                                                                                                                          |
| <code>inetSockSettingReadTimeout</code>    | The default timeout value for reads when the application uses the event mechanism. The time since last receiving data from a socket is monitored and a timeout error status event is returned from <code>INetLibGetEvent</code> if the timeout is exceeded. |
| <code>inetSockSettingContentVersion</code> | Content version number. Read-only.                                                                                                                                                                                                                          |

## INetStatusEnum

The `INetStatusEnum` enum specifies the status of the socket. The status is returned in the [inetSockStatusChangeEvent](#) event structure and by the call [INetLibSockStatus](#).

---

```
typedef enum {
inetStatusNew, // just opened
inetStatusResolvingName, // looking up host address
inetStatusNameResolved, // found host address
inetStatusConnecting, // connecting to host
inetStatusConnected, // connected to host
inetStatusSendingRequest, // sending request
inetStatusWaitingForResponse, // waiting for response
inetStatusReceivingResponse, // receiving response
inetStatusResponseReceived, // response received
inetStatusClosingConnection, // closing connection
inetStatusClosed, // closed
inetStatusAcquiringNetwork, // network temporarily
                                // unreachable; socket on
hold
inetStatusPrvInvalid = 30 // internal value, not returned by
                                // INetMgr. Should be
last.
} INetStatusEnum;
```

---

#### Value Descriptions

|                                           |                                                 |
|-------------------------------------------|-------------------------------------------------|
| <code>inetStatusNew</code>                | Just opened                                     |
| <code>inetStatusResolvingName</code>      | Looking up host address                         |
| <code>inetStatusNameResolved</code>       | Found host address                              |
| <code>inetStatusConnecting</code>         | Connecting to host                              |
| <code>inetStatusConnected</code>          | Connected to host                               |
| <code>inetStatusSendingRequest</code>     | Sending request                                 |
| <code>inetStatusWaitingForResponse</code> | Waiting for response                            |
| <code>inetStatusReceivingResponse</code>  | Receiving response                              |
| <code>inetStatusResponseReceived</code>   | Response received                               |
| <code>inetStatusClosingConnection</code>  | Closing connection                              |
| <code>inetStatusClosed</code>             | Connection closed                               |
| <code>inetStatusAcquiringNetwork</code>   | Network temporarily unreachable; socket on hold |
| <code>inetStatusPrvInvalid</code>         | Not used                                        |

## Internet Library Constants

### Configuration Aliases

The constants listed here specify Internet library network configuration alias names. Most of the Internet library API requires a configuration index rather than a name. Use [INetLibConfigIndexFromName](#) to obtain the alias's index from the name. For more information, see [INetConfigNameType](#).

The following aliases are defined for configuration names:

| <b>Alias</b>                        | <b>Name string</b>          | <b>Description</b>                                                                                                                                                                                                                          |
|-------------------------------------|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>inetCfgNameDefault</code>     | <code>".Default"</code>     | Initially points to a generic configuration with no proxy. This uses the configuration set by the user in the Network preferences panel.                                                                                                    |
| <code>inetCfgNameDefWireline</code> | <code>".DefWireline"</code> | Initially points to a generic configuration with no proxy. This uses the configuration set by the user in the Network preferences panel.                                                                                                    |
| <code>inetCfgNameDefWireless</code> | <code>".DefWireless"</code> | Initially points to a generic configuration with no proxy. This uses the configuration set by the user in the Network preferences panel.                                                                                                    |
| <code>inetCfgNameCTPDefault</code>  | <code>".CTPDefault"</code>  | Initially points to either <code>".CTPWireless"</code> (on Palm VII <sup>®</sup> units) or <code>".CTPWireline"</code> (on all other units). On the Palm VII unit, the Web Clipping Application Viewer application uses this configuration. |
| <code>inetCfgNameCTPWireline</code> | <code>".CTPWireline"</code> | Initially points to a wireline configuration that uses the Palm Web Clipping Proxy server.                                                                                                                                                  |
| <code>inetCfgNameCTPWireless</code> | <code>".CTPWireless"</code> | Initially points to a wireless configuration that uses the Palm.Net <sup>™</sup> wireless system and the Palm Web Clipping Proxy server.                                                                                                    |

---

## URL Info Constants

The `inetURLInfoFlag...` constants convey information about a URL and are returned by the function [INetLibURLGetInfo](#).

## Internet Library

### Internet Library Constants

---

| Constant                              | Value  | Description                     |
|---------------------------------------|--------|---------------------------------|
| <code>inetURLInfoFlagIsSecure</code>  | 0x0001 | URL was encrypted.              |
| <code>inetURLInfoFlagIsRemote</code>  | 0x0002 | URL was retrieved from the net. |
| <code>inetURLInfoFlagIsInCache</code> | 0x0004 | URL is stored in the cache.     |

---

### URL Open Constants

The `inetOpenURLFlag...` constants control how the [INetLibURLOpen](#) call operates with respect to caching and encryption. These flags are also used for the [inetSockSettingFlags](#) socket setting.

| Constant                                | Value  | Description                                                                        |
|-----------------------------------------|--------|------------------------------------------------------------------------------------|
| <code>inetOpenURLFlagLookInCache</code> | 0x0001 | Read data from the cache, if available.                                            |
| <code>inetOpenURLFlagKeepInCache</code> | 0x0002 | Store the item in the cache, overwriting any other entries with an equivalent URL. |
| <code>inetOpenURLFlagForceEncOn</code>  | 0x0008 | Use encryption even if scheme does not desire it.                                  |
| <code>inetOpenURLFlagForceEncOff</code> | 0x0010 | Do not use encryption even if scheme desires it.                                   |

---

## Internet Library Functions

### **INetLibCacheGetObject**

**Purpose** Returns information about an entry in the cache database, including a handle to the record. Either the URL or the unique ID can be used to find the cache entry.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibCacheGetObject (UInt16 libRefnum, MemHandle clientParamH, UInt8 *urlTextP, UInt32 uniqueID, INetCacheInfoPtr cacheInfoP)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `clientParamH` Inet handle allocated by `INetLibOpen`.
- > `urlTextP` Pointer to URL text string to find. If this parameter is `NULL`, then `uniqueID` is used to find the entry.
- > `uniqueID` Unique ID of the cache entry to find. This value can be obtained by calling [INetLibCacheList](#). This parameter is ignored if `urlTextP` is specified.
- <- `INetCacheInfoPtr` Pointer to a structure where information about the cache entry is returned. See the Comments section for details.

#### **Result**

|                                   |                                            |
|-----------------------------------|--------------------------------------------|
| <code>0</code>                    | No error                                   |
| <code>inetErrParamsInvalid</code> | One or more of the parameters are invalid. |

## Internet Library

### Internet Library Functions

---

**Comments** The `INetCacheInfoPtr` type returned from this function is defined as a pointer to an `INetCacheInfoType` structure, which has the following definition:

```
typedef struct {
    MemHandle recordH; // handle to the cache
    record
    INetContentTypeEnum contentType;
    INetCompressionTypeEnum encodingType;
    UInt32 uncompressedDataSize;
    UInt8 flags; // unused
    UInt8 reserved;
    UInt16 dataOffset; // offset to content
    UInt16 dataLength; // size of content
    UInt16 urlOffset; // offset to URL
    UInt32 viewTime; // time last viewed
    UInt32 createTime; // time entry was created
    UInt16 murlOffset; // offset to master URL
} INetCacheInfoType, *INetCacheInfoPtr;
```

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibCacheList

**Purpose** Returns an item from the cache list, based on its URL and index in the list.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibCacheList (UInt16 libRefnum, MemHandle inetH, UInt8 *cacheIndexURLP, UInt16 *indexP, UInt32 *uidP, INetCacheEntryP cacheP)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `inetH` Inet handle allocated by `INetLibOpen`.

|                                   |                                                                                                                                                                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; cacheIndexURLP</code> | Pointer to a master URL string. Cache entries indexed with this master URL are returned. The Web Clipping Application Viewer sets the master URL of a cache page to the URL of the active PQA, so all pages linked from the PQA have the same master URL.                   |
| <code>&lt;-&gt; indexP</code>     | Pointer to the index of the entry. Specify an index to find entries at this index or higher in the list. Specify <code>NULL</code> to search from the beginning, the first time you call this function. The index of the entry following the one found is returned on exit. |
| <code>&lt;- uidP</code>           | Pointer to a long value where the unique ID of the found cache entry is returned.                                                                                                                                                                                           |
| <code>&lt;- cacheP</code>         | Pointer to a structure where information about the found cache entry is returned. See the Comments section for details.                                                                                                                                                     |

### Result

|                                   |                                                                |
|-----------------------------------|----------------------------------------------------------------|
| <code>0</code>                    | No error                                                       |
| <code>inetErrTypeNotCached</code> | Cache entry under requested index not found                    |
| <code>inetErrParamsInvalid</code> | The <code>cacheIndexURLP</code> parameter is <code>NULL</code> |
| <code>inetErrCacheInvalid</code>  | The cache database doesn't exist                               |

### Comments

This function first sorts the list of cache entries by URL. Then it returns in `uidP` the unique ID of the first cache entry with an index equal to or greater than `indexP`. The `indexP` value is updated to point to the next entry upon return.

To generate a complete list of cache entries having the same master URL (as for a history list), call this function repeatedly, always specifying the updated `index`, until it returns the error `inetErrTypeNotCached`.

## Internet Library

### Internet Library Functions

---

Note that a URL can exist multiple times in the Web Clipping Application Viewer cache database, thus the need for the `uidP` value.

The `INetCacheEntryP` type returned from this function is defined as a pointer to an `INetCacheEntryType` structure, which has the following definition:

```
typedef struct {
    UInt8 *urlP; // ptr to URL string
    UInt16 urlLen; // length of URL string
    UInt8 *titleP; // ptr to title string
    UInt16 titleLen; // length of title string
    UInt32 lastViewed; // time last viewed
                    // seconds since 1/1/1904
    UInt32 firstViewed; // time first viewed
                    // seconds since 1/1/1904
} INetCacheEntryType, *INetCacheEntryP;
```

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibCheckAntennaState

**Purpose** Checks the antenna state and displays a dialog asking the user to raise it if it is down.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibCheckAntennaState(UInt16 refNum)`

**Parameters** `-> refNum` Refnum of the Internet library.

### Result

|                               |                                               |
|-------------------------------|-----------------------------------------------|
| <code>0</code>                | The user raised the antenna.                  |
| <code>netErrUserCancel</code> | The user closed the dialog by tapping Cancel. |

This call can also return data manager errors if it fails internally.

**Comments** Applications don't need to check the antenna state by using this call. If an application opens the Internet library, the Internet library checks the antenna state when needed and displays the dialog to prompt the user to raise the antenna.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## **INetLibClose**

**Purpose** Closes up and frees an inet handle. Closes or decrements the open count of the net library.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibClose (UInt16 libRefnum,  
MemHandle inetH)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `inetH` Inet handle allocated by `INetLibOpen`.

**Result**

0 No error

**Comments** This call must be made by an application when it's done with the Internet library. It closes any Internet sockets open by the application, disposes the memory referenced by the given inet handle, and calls `NetLibClose`, if necessary, to close the net Library or decrement its open count.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibOpen](#)

### INetLibConfigAliasGet

**Purpose** Determines to which configuration a built-in alias points.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigAliasGet (UInt16 refNum,  
UInt16 aliasIndex, UInt16 *indexP,  
Boolean *isAnotherAliasP)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `aliasIndex` Index of alias configuration to query. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by [INetLibConfigList](#), or the index returned by [INetLibConfigIndexFromName](#).
- <- `indexP` Pointer where the index of the configuration pointed to by `aliasIndex` is returned. 0 is returned if `aliasIndex` does not point to another configuration.
- <- `isAnotherAliasP` If `*indexP` is the index of another alias configuration, this Boolean is set to `true`.

#### Result

|                                    |                                                       |
|------------------------------------|-------------------------------------------------------|
| 0                                  | No error                                              |
| <code>inetErrParamsInvalid</code>  | <code>aliasIndex</code> is not valid                  |
| <code>inetErrConfigNotAlias</code> | <code>aliasIndex</code> is not an alias configuration |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibConfigAliasSet](#)

## INetLibConfigAliasSet

- Purpose** Points any of the built-in aliases (".DefWireline", ".DefWireless", etc.) to a given defined configuration.
- Declared In** `INetMgr.h`
- Prototype** `Err INetLibConfigAliasSet (UInt16 refNum, UInt16 configIndex, UInt16 aliasToIndex)`
- Parameters**
- > `libRefnum` Refnum of the Internet library.
  - > `configIndex` Index of configuration to set. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by [INetLibConfigList](#), or the index returned by [INetLibConfigIndexFromName](#).
  - > `aliasToIndex` Index of configuration that the alias identified by `configIndex` is to point to. Specify 0 to remove an existing alias assignment.
- Result**
- |                                            |                                                                    |
|--------------------------------------------|--------------------------------------------------------------------|
| 0                                          | No error                                                           |
| <code>inetErrConfigNotAlias</code>         | <code>configIndex</code> is not an alias configuration             |
| <code>inetErrParamsInvalid</code>          | <code>configIndex</code> or <code>aliasToIndex</code> is not valid |
| <code>inetErrConfigCantPointToAlias</code> | Alias doesn't point to a real entry                                |
- Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.
- See Also** [INetLibConfigAliasGet](#)

### INetLibConfigDelete

**Purpose** Deletes a configuration.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigDelete (UInt16 refNum,  
UInt16 index)`

**Parameters**

|           |                                                                                                                                                                                                                                                                                                                     |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> refnum | Refnum of the Internet library.                                                                                                                                                                                                                                                                                     |
| -> index  | Index of configuration to delete. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by <a href="#">INetLibConfigList</a> , or the index returned by <a href="#">INetLibConfigIndexFromName</a> . |

**Result**

|                                      |                                            |
|--------------------------------------|--------------------------------------------|
| 0                                    | No error                                   |
| <code>inetErrParamsInvalid</code>    | Index not valid                            |
| <code>inetErrConfigCantDelete</code> | Attempted to delete an alias configuration |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibConfigIndexFromName](#), [INetLibConfigList](#)

## INetLibConfigIndexFromName

- Purpose** Returns the index of a configuration given it's name.
- Declared In** `INetMgr.h`
- Prototype** `Err INetLibConfigIndexFromName (UInt16 refNum, INetConfigNamePtr nameP, UInt16 *indexP)`
- Parameters**
- |           |                                                                                                                      |
|-----------|----------------------------------------------------------------------------------------------------------------------|
| -> refnum | Refnum of the Internet library.                                                                                      |
| -> nameP  | Pointer to an <a href="#">INetConfigNameType</a> structure that names the configuration whose index you want to get. |
| <- indexP | Pointer where the index of the configuration identified in nameP is returned.                                        |
- Result**
- |                                    |                                             |
|------------------------------------|---------------------------------------------|
| 0                                  | No error                                    |
| <code>inetErrConfigNotFound</code> | Could not find requested configuration name |
- Comments** If you name an alias, this routine returns the index of the alias entry, not the configuration the alias points to. This way the alias can be pointed to a different configuration.
- Applications should store the index of the configuration they're using, rather than the name, so that they won't be confused if the user edits the name of the configuration from the Preferences panel.
- Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.
- See Also** [INetLibConfigList](#)

### INetLibConfigList

- Purpose** Returns an array containing a list of the available Internet library network configurations.
- Declared In** `INetMgr.h`
- Prototype**  
`Err INetLibConfigList (UInt16 refNum,  
INetConfigNameType nameArray[],  
UInt16 *arrayEntriesP)`
- Parameters**
- > `refnum` Refnum of the Internet library.
  - > `nameArray` Pointer to an array of [INetConfigNameType](#) structs that is to be filled in by this routine.
  - <-> `arrayEntriesP`  
On entry, a pointer to the number of entries available in `nameArray`; on exit, a pointer to the total number of entries in the system (which could exceed the size of the array you pass in).
- Result**
- 0 No error
- Comments** This routine can be used to obtain a list of available configurations for selection by the user.
- Note that the built-in alias configurations, which start with a period, should not be displayed to the user as selectable choices. They are designed for internal use by applications that need a predetermined type of service (like ".CTPWireless" for PQA applications.) Also, any configurations that start with an underscore, like "\_CTPRAM", should not be displayed. These typically are configurations created by the Internet library for internal use and cannot be edited using the Network preferences panel.
- Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.
- See Also** [INetLibConfigMakeActive](#)

## **INetLibConfigMakeActive**

- Purpose** Makes the given configuration active without having to close and reopen the Internet library by using `INetLibOpen`.
- Declared In** `INetMgr.h`
- Prototype** `Err INetLibConfigMakeActive (UInt16 refNum, MemHandle inetH, UInt16 configIndex)`
- Parameters**
- > `libRefnum` Refnum of the Internet library.
  - > `inetH` Inet handle allocated by `INetLibOpen`.
  - > `configIndex` Index of configuration to activate. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by [INetLibConfigList](#), or the index returned by [INetLibConfigIndexFromName](#).
- Result**
- 0 No error
- Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.
- See Also** [INetLibConfigSaveAs](#), [INetLibConfigList](#), [INetLibConfigIndexFromName](#)

### INetLibConfigRename

**Purpose** Renames a configuration.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigRename (UInt16 refNum,  
UInt16 index, INetConfigNamePtr newNameP)`

**Parameters**

|                           |                                                                                                                                                                                                                                                                                                                     |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>libRefnum</code> | Refnum of the Internet library.                                                                                                                                                                                                                                                                                     |
| -> <code>index</code>     | Index of configuration to rename. This is the index of the configuration in the internal array of configurations stored by the system. This is the same as the index of the item in the array returned by <a href="#">INetLibConfigList</a> , or the index returned by <a href="#">INetLibConfigIndexFromName</a> . |
| -> <code>newNameP</code>  | Pointer to an <a href="#">INetConfigNameType</a> structure holding the new name of the configuration. The name cannot start with a period or an underscore.                                                                                                                                                         |

#### Result

|                                      |                                                                                                      |
|--------------------------------------|------------------------------------------------------------------------------------------------------|
| 0                                    | No error                                                                                             |
| <code>inetErrConfigBadName</code>    | Trying to save as an alias (beginning with ".") or as a built-in configuration (beginning with "_"). |
| <code>inetErrParamsInvalid</code>    | Invalid index                                                                                        |
| <code>inetErrConfigCantDelete</code> | Configuration to be renamed is either an alias or a built-in configuration                           |

**Comments** After renaming, the configuration index stays the same so that applications that are set up to use that configuration will still work

correctly. Note that built-in configuration aliases (ones that start with a period) cannot be renamed.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## **INetLibConfigSaveAs**

**Purpose** Saves the current network configuration settings under the given name.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibConfigSaveAs (UInt16 refNum,  
MemHandle inetH, INetConfigNamePtr nameP)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `inetH` Inet handle allocated by `INetLibOpen`.
- > `nameP` Pointer to an [INetConfigNameType](#) structure holding the name of the configuration. The name cannot start with a period or an underscore.

### **Result**

|                                   |                                                                                                      |
|-----------------------------------|------------------------------------------------------------------------------------------------------|
| <code>0</code>                    | No error                                                                                             |
| <code>inetErrConfigBadName</code> | Trying to save as an alias (beginning with ".") or as a built-in configuration (beginning with "_"). |
| <code>inetErrConfigTooMany</code> | The internal configurations table is full. No more entries can be stored.                            |

**Comments** If the configuration name specified already exists, it is replaced with the new settings.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

### INetLibGetEvent

- Purpose** A replacement for `EvtGetEvent` that informs an application of status changes to Internet sockets as well as user interface events.
- Declared In** `INetMgr.h`
- Prototype**  
`void INetLibGetEvent (UInt16 libRefnum,  
MemHandle inetH, INetEventType *eventP,  
Int32 timeout)`
- Parameters**
- > `libRefnum` Refnum of the Internet library.
  - > `inetH` Inet handle allocated by `INetLibOpen`, or `NULL`.
  - <-> `eventP` The event structure is returned via this pointer.
  - > `timeout` Timeout in ticks. Specify `evtWaitForever` to wait forever.
- Result**
- 0 No error
- Comments** This call is designed to replace [EvtGetEvent](#) in applications which use the Internet library. For convenience, if `inetH` is `NULL`, `INetLibGetEvent` is equivalent to `EvtGetEvent`.
- `INetLibGetEvent` returns two additional events besides those returned by `EvtGetEvent`: [inetSockReadyEvent](#) and [inetSockStatusChangeEvent](#).
- Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.
- See Also** [INetLibSockStatus](#), [INetLibURLOpen](#), [INetLibSockOpen](#), [INetLibSockRead](#)

## INetLibOpen

**Purpose** Creates a new application inet handle structure. Opens or increments the open count of the net library.

**Declared In** INetMgr.h

**Prototype** Err INetLibOpen (UInt16 libRefnum, UInt16 config, UInt32 flags, DmOpenRef cacheRef, UInt32 cacheSize, MemHandle \*inetHP)

**Parameters**

- > libRefnum Refnum of the Internet library. Pass the value "INet.lib" to [SysLibFind](#) to return this refnum.
- > config Indicates the type of network service desired by the application. Returned by [INetLibConfigIndexFromName](#).
- > flags Currently unused; set to 0.
- > cacheRef Document cache database reference. Obtain this by using one of the [DmOpenDatabase...](#) calls. Pass NULL if you don't want to use a cache.
- > cacheSize Maximum size of the document cache (in bytes). This is ignored if you pass NULL for cacheRef.
- <- inetHP Pointer to a handle variable.

### **Result**

|                              |                                                                |
|------------------------------|----------------------------------------------------------------|
| 0                            | No error                                                       |
| inetErrTooManyClients        | Too many clients opened already                                |
| inetErrIncompatibleInterface | The net library is already open with an incompatible interface |

## Internet Library

### Internet Library Functions

---

**Comments** This call must be made by an application before it can use any other Internet library calls. This call opens the Internet library and returns a pointer to an inet handle, which is then passed to subsequent calls to the Internet library. Every application that opens the Internet library gets its own unique inet handle.

When an application is done using the Internet library, it must call [INetLibClose](#), which closes both the Internet library and the net library, if necessary.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibClose](#), [INetLibConfigIndexFromName](#)

## INetLibSettingGet

**Purpose** Retrieves current settings for an inet handle.

**Declared In** INetMgr.h

**Prototype** Err INetLibSettingGet (UInt16 libRefnum,  
MemHandle inetH, UInt16 setting, void \*bufP,  
UInt16 \*bufLenP)

**Parameters**

|              |                                                                                          |
|--------------|------------------------------------------------------------------------------------------|
| -> libRefnum | Refnum of the Internet library.                                                          |
| -> inetH     | Inet handle allocated by INetLibOpen.                                                    |
| -> setting   | The setting to get. Specify one of the <a href="#">INetSettingEnum</a> enumerated types. |
| <- bufP      | Pointer to buffer where the return value is to be put.                                   |
| <-> bufLenP  | Size of bufP on entry. Size of setting value on exit.                                    |

### Result

0 No error

|                                        |                                                          |
|----------------------------------------|----------------------------------------------------------|
| <code>inetErrParamsInvalid</code>      | Invalid setting requested                                |
| <code>inetErrSettingSizeInvalid</code> | *bufLenP is the incorrect size for the requested setting |

**Comments** This call can be used to retrieve the current settings of an inet handle. Some settings have default values that are stored in the system preferences database; see [INetSettingEnum](#) for details.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibOpen](#), [INetLibSettingSet](#), [INetSettingEnum](#)

## INetLibSettingSet

**Purpose** Changes a setting for an inet handle.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSettingSet (UInt16 libRefnum, MemHandle inetH, UInt16 setting, void *bufP, UInt16 bufLen)`

**Parameters**

|                           |                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------|
| -> <code>libRefnum</code> | Refnum of the Internet library.                                                          |
| -> <code>inetH</code>     | Inet handle allocated by <code>INetLibOpen</code> .                                      |
| -> <code>setting</code>   | The setting to set. Specify one of the <a href="#">INetSettingEnum</a> enumerated types. |
| -> <code>bufP</code>      | Pointer to the new setting value.                                                        |
| -> <code>bufLen</code>    | Size of the value in <code>bufP</code> .                                                 |

**Result**

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

## Internet Library

### Internet Library Functions

---

|                                        |                                                                     |
|----------------------------------------|---------------------------------------------------------------------|
| <code>inetErrParamsInvalid</code>      | Invalid setting specified                                           |
| <code>inetErrSettingSizeInvalid</code> | <code>bufLen</code> is the incorrect size for the specified setting |

**Comments** Any changes made to the settings last only as long as the `inetH` is around (until [INetLibClose](#) is called) and do not affect other applications that might be using the Internet library.

An important note is that settings made through this call essentially change the default values for any sockets subsequently created through [INetLibURLOpen](#) or [INetLibSockOpen](#).

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSettingGet](#), [INetSettingEnum](#)

## INetLibSockClose

**Purpose** Closes an inet socket handle.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockClose (UInt16 libRefnum, MemHandle socketH)`

**Parameters**

|                              |                                 |
|------------------------------|---------------------------------|
| <code>-&gt; libRefnum</code> | Refnum of the Internet library. |
| <code>-&gt; socketH</code>   | Handle of the socket to close.  |

**Result**

|   |          |
|---|----------|
| 0 | No error |
|---|----------|

**Comments** This call closes down and releases all memory associated with a socket created by [INetLibSockOpen](#) or [INetLibURLOpen](#).

## Internet Library

### Internet Library Functions

---

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockOpen](#), [INetLibSockStatus](#), [INetLibGetEvent](#)

## INetLibSockHTTPAttrGet

**Purpose** Queries HTTP request header formed by the local host, or the response header information returned by a remote host.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockHTTPAttrGet (UInt16 libRefnum, MemHandle sockH, UInt16 attr, UInt16 attrIndex, void *bufP, UInt32 *bufLenP)`

**Parameters**

|              |                                                                                                   |
|--------------|---------------------------------------------------------------------------------------------------|
| -> libRefnum | Refnum of the Internet library.                                                                   |
| -> sockH     | Handle (allocated by <code>INetLibSockOpen</code> or <code>INetLibURLOpen</code> ) of the socket. |
| -> attr      | The attribute to get. Specify one of the <a href="#">INetHTTPAttrEnum</a> values.                 |
| -> attrIndex | The attribute index (if any). Currently unused.                                                   |
| <- bufP      | Pointer to the address where the result is returned.                                              |
| <-> bufLenP  | Pointer to the size of bufP on entry; size of returned value on exit.                             |

### Result

|                                           |                                                        |
|-------------------------------------------|--------------------------------------------------------|
| 0                                         | No error                                               |
| <code>inetErrSettingNotImplemented</code> | Invalid setting specified                              |
| <code>inetErrSettingSizeInvalid</code>    | bufLen is the incorrect size for the specified setting |

**Comments** This call queries either the request header formed by `INetLibSockHTTPReqCreate` and `INetLibSockHTTPAttrSet`, or the response header returned by the remote host.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockHTTPReqCreate](#)

## **INetLibSockHTTPAttrSet**

**Purpose** Adds additional HTTP request headers to an HTTP request in a socket.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockHTTPAttrSet (UInt16 libRefnum, MemHandle sockH, UInt16 attr, UInt16 attrIndex, UInt8 *bufP, UInt16 bufLen, UInt16 flags)`

**Parameters**

|                           |                                                                                                   |
|---------------------------|---------------------------------------------------------------------------------------------------|
| -> <code>libRefnum</code> | Refnum of the Internet library.                                                                   |
| -> <code>sockH</code>     | Handle (allocated by <code>INetLibSockOpen</code> or <code>INetLibURLOpen</code> ) of the socket. |
| -> <code>attr</code>      | The attribute to set. Specify one of the <a href="#">INetHTTPAttrEnum</a> values.                 |
| -> <code>attrIndex</code> | The attribute index (if any). Currently unused.                                                   |
| -> <code>bufP</code>      | Pointer to additional header text to add.                                                         |
| -> <code>bufLen</code>    | Length of <code>bufP</code> .                                                                     |
| -> <code>flags</code>     | Flags that control the addition of new headers. Currently unused.                                 |

**Result**

0 No error

## Internet Library

### Internet Library Functions

---

|                                           |                                                                     |
|-------------------------------------------|---------------------------------------------------------------------|
| <code>inetErrSettingNotImplemented</code> | Invalid setting specified                                           |
| <code>inetErrSettingSizeInvalid</code>    | <code>bufLen</code> is the incorrect size for the specified setting |

**Comments** This call modifies attributes of an HTTP request formed by `INetLibSockHTTPReqCreate`. Generally, attributes are set only before calling `INetLibSockHTTPReqSend`.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockHTTPReqCreate](#), [INetLibSockHTTPReqSend](#)

## INetLibSockHTTPReqCreate

**Purpose** Forms an HTTP request for the socket.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockHTTPReqCreate (UInt16 libRefnum, MemHandle sockH, UInt8 *verbP, UInt8 *resNameP, UInt8 *refererP)`

**Parameters**

|                              |                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------|
| <code>-&gt; libRefnum</code> | Refnum of the Internet library.                                                                   |
| <code>-&gt; sockH</code>     | Handle (allocated by <code>INetLibSockOpen</code> or <code>INetLibURLOpen</code> ) of the socket. |
| <code>-&gt; verbP</code>     | Reserved for future use.                                                                          |
| <code>-&gt; resNameP</code>  | Pointer to a string holding the name of the resource to get or put.                               |
| <code>-&gt; refererP</code>  | Pointer to a string holding the name of the referring URL, or <code>NULL</code> if none.          |

### Result

|                                   |                    |
|-----------------------------------|--------------------|
| <code>0</code>                    | No error           |
| <code>inetErrParamsInvalid</code> | Not an HTTP socket |

**Comments** This call forms an HTTP request for the socket. The request is not actually sent to the remote host until [INetLibSockHTTPReqSend](#) is called. The HTTP verb used in the request is determined by the value of the `writeP` parameter passed to `INetLibSockHTTPReqSend`: if this parameter is NULL, "GET" is used. Otherwise, "POST" is used.

After a call to `INetLibSockHTTPReqCreate` but before a call to `INetLibSockHTTPReqSend`, the application can add additional HTTP request headers using [INetLibSockHTTPAttrSet](#).

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockHTTPAttrSet](#), [INetLibSockHTTPReqSend](#)

## INetLibSockHTTPReqSend

**Purpose** Sends an HTTP request to the remote host or looks for data in the cache.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockHTTPReqSend (UInt16 libRefnum, MemHandle sockH, void *writeP, UInt32 writeLen, Int32 timeout)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `sockH` Handle (allocated by `INetLibSockOpen` or `INetLibURLOpen`) of the socket.
- > `writeP` Pointer to additional data to send after the request headers. Usually used for POST and PUT operations.
- > `writeLen` Number of bytes in `writeP`.

## Internet Library

### Internet Library Functions

---

-> timeout      Timeout in ticks.

#### Result

|                                        |                                        |
|----------------------------------------|----------------------------------------|
| 0                                      | No error                               |
| <code>inetErrRequestTooLong</code>     | Request too big                        |
| <code>inetErrEncryptionNotAvail</code> | Encryption requested but not available |

#### Comments

This call sends an HTTP request created by `INetLibSockHTTPReqCreate` and `INetLibSockHTTPAttrSet` to the remote host. If this is an POST or PUT operation, the data to write can be specified in `writeP`.

`INetLibSockHTTPReqSend` doesn't always do network I/O. If the proper socket flag is set, it checks first to see if the requested data is already in the cache. If it is, then a pointer to the cached data is stored in the socket and the socket status is updated to show that data is ready to be read. This will trigger an [inetSockReadyEvent](#) event.

The socket flag (`inetOpenURLFlagLookInCache`) that causes the cache to be checked first can be set via the `flags` parameter to [INetLibURLOpen](#) or by calling [INetLibSockSettingSet](#) with the appropriate setting (`inetSockSettingFlags`).

After sending the request, the application can wait for the response to arrive by either polling `INetLibSockStatus` until the `inputReady` boolean is set (not recommended), or by waiting for an `inetSockReadyEvent` event from `INetLibGetEvent` (preferred).

**Compatibility**      Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also**      [INetLibSockHTTPReqCreate](#), [INetLibSockHTTPAttrSet](#), [INetLibGetEvent](#)

## INetLibSockOpen

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |              |                                 |                       |                                       |                           |                                                                                      |           |                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|---------------------------------|-----------------------|---------------------------------------|---------------------------|--------------------------------------------------------------------------------------|-----------|-------------------------------------------------------------|
| <b>Purpose</b>            | Creates and returns a new inet socket handle.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |              |                                 |                       |                                       |                           |                                                                                      |           |                                                             |
| <b>Declared In</b>        | INetMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |              |                                 |                       |                                       |                           |                                                                                      |           |                                                             |

| inetErrSchemeNotSupported | Requested URL scheme not supported                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                 |                       |                                       |                           |                                                                                      |           |                                                             |
| <b>Comments</b>           | <p>This call creates a new socket for the given scheme. No network I/O is performed. This is a relatively low level call that can be used in place of INetLibURLOpen when finer control over the socket settings is required.</p> <p>Using INetLibURLOpen, an HTTP request can be handled with the simple sequence: INetLibURLOpen, INetLibSockRead, and INetLibSockClose. When using INetLibSockOpen, the same HTTP request would be handled by replacing the INetLibURLOpen call with the sequence: INetLibSockOpen, INetLibSockSettingSet (optional), INetLibSockConnect, INetLibSockHTTPReqCreate, INetLibSockHTTPAttrSet (optional), and INetLibSockHTTPReqSend.</p> |              |                                 |                       |                                       |                           |                                                                                      |           |                                                             |

## Internet Library

### Internet Library Functions

---

The use of `INetLibSockOpen` allows an application finer control over the socket settings (by calling `INetLibSockSettingSet`) and the HTTP request headers (by calling `INetLibSockHTTPAttrSet`).

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibOpen](#), [INetLibURLOpen](#), [INetLibSockRead](#), [INetLibSockClose](#), [INetLibSockSettingSet](#), [INetLibSockHTTPAttrSet](#)

## INetLibSockRead

**Purpose** Reads data from a socket.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibSockRead (UInt16 libRefnum, MemHandle sockH, void *bufP, UInt32 reqBytes, UInt32 *actBytesP, Int32 timeout)`

**Parameters**

|              |                                                                        |
|--------------|------------------------------------------------------------------------|
| -> libRefnum | Refnum of the Internet library.                                        |
| -> sockH     | Inet handle allocated by <code>INetLibOpen</code> .                    |
| -> bufP      | Pointer to buffer where the data is placed.                            |
| -> reqBytes  | Requested number of bytes.                                             |
| <- actBytesP | Pointer to the actual number of bytes read.                            |
| -> timeout   | Timeout in ticks. Specify <code>evtWaitForever</code> to wait forever. |

### Result

0 No error

**Comments** This call attempts to read `reqBytes` bytes from the given socket. It returns the actual number of bytes read in `*actBytesP`. If the connection with the remote host has been closed, `*actBytesP` contains 0 on exit.

Note that it is normal for the actual bytes read to be less than the requested number of bytes. The application should be prepared to call this routine repeatedly until the desired number of bytes have been read or until `*actBytesP` contains 0, indicating the connection has been closed, or until an error is returned.

This call returns as much data as possible without blocking, however, if no data is available to be read, it does block until at least one byte is available.

Normally, applications will wait for an [inetSockReadyEvent](#) from [INetLibGetEvent](#) before calling `INetLibSockRead`. Alternatively, the application could call [INetLibSockStatus](#) to determine if the socket has any data ready (not recommended), or could simply rely on `INetLibSockRead` to block until at least one byte is available to read. If no data is available before the timeout expires, `inetErrReadTimeout` error is returned.

**Compatibility**    Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also**        [INetLibURLOpen](#), [INetLibSockOpen](#), [INetLibSockStatus](#),  
[INetLibSockClose](#), [INetLibGetEvent](#)

## **INetLibSockSettingGet**

**Purpose**         Retrieves a socket setting.

**Declared In**    `INetMgr.h`

**Prototype**

```
Err INetLibSockSettingGet (UInt16 libRefnum,
MemHandle socketH, UInt16 setting, void *bufP,
UInt16 *bufLenP)
```

**Parameters**

- > `libRefnum`    Refnum of the Internet library.
- > `socketH`        Handle (allocated by `INetLibSockOpen` or `INetLibURLOpen`) of the socket to get a setting from.
- > `setting`        The setting to get. Specify one of the [INetSockSettingEnum](#) values.

## Internet Library

### Internet Library Functions

---

|             |                                                            |
|-------------|------------------------------------------------------------|
| <- bufP     | Pointer to buffer where the setting value is to be placed. |
| <-> bufLenP | Size of bufP on entry; size of returned value on exit.     |

#### Result

|                           |                                                          |
|---------------------------|----------------------------------------------------------|
| 0                         | No error                                                 |
| inetErrParamsInvalid      | Invalid setting requested                                |
| inetErrSettingSizeInvalid | *bufLenP is the incorrect size for the requested setting |

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockSettingSet](#)

## INetLibSockSettingSet

**Purpose** Changes a setting of a socket.

**Declared In** INetMgr.h

**Prototype** Err INetLibSockSettingSet (UInt16 libRefnum, MemHandle socketH, UInt16 setting, void \*bufP, UInt16 bufLen)

**Parameters**

|              |                                                                                    |
|--------------|------------------------------------------------------------------------------------|
| -> libRefnum | Refnum of the Internet library.                                                    |
| -> socketH   | Handle (allocated by INetLibSockOpen or INetLibURLOpen) of the socket to set.      |
| -> setting   | The setting to set. Specify one of the <a href="#">INetSockSettingEnum</a> values. |
| -> bufP      | Pointer to buffer containing the new setting value.                                |

-> bufLen            Size of new setting in bufP.

**Result**

|                              |                                              |
|------------------------------|----------------------------------------------|
| 0                            | No error                                     |
| inetErrSettingNotImplemented | Invalid setting specified                    |
| inetErrSettingSizeInvalid    | bufLen is the incorrect size for the setting |

**Comments**      This call can be use to override a general setting for a particular socket.

**Compatibility**    Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also**        [INetLibSockSettingGet](#)

## **INetLibSockStatus**

**Purpose**            Retrieves the current status of a socket.

**Declared In**      INetMgr.h

**Prototype**        Err INetLibSockStatus (UInt16 libRefnum,  
MemHandle socketH, UInt16 \*statusP,  
Err \*sockErrP, Boolean \*inputReadyP,  
Boolean \*outputReadyP)

**Parameters**

|              |                                                                                                                           |
|--------------|---------------------------------------------------------------------------------------------------------------------------|
| -> libRefnum | Refnum of the Internet library.                                                                                           |
| -> socketH   | Handle (allocated by INetLibSockOpen or INetLibURLOpen) of the socket to get status on.                                   |
| <- statusP   | Pointer to the address where the status is returned. The status will be one of the <a href="#">INetStatusEnum</a> values. |
| <- sockErrP  | Currently unused.                                                                                                         |

## Internet Library

### Internet Library Functions

---

<- inputReadyP Pointer to a Boolean; true is returned if the socket has data available to read.

<- outputReadyP  
Pointer to a Boolean; true is returned if the socket can accept data for writing.

#### Result

0 No error

**Comments** Most applications that use `INetLibGetEvent` will rarely need to use this call since socket status changes are returned in the event structure.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibURLOpen](#), [INetLibSockOpen](#), [INetLibSockRead](#), [INetLibGetEvent](#)

## INetLibURLCrack

**Purpose** Cracks a URL text string into its components.

**Declared In** `INetMgr.h`

**Prototype** `Err INetLibURLCrack (UInt16 libRefnum, UInt8 *urlTextP, INetURLType *urlP)`

**Parameters**

- > `libRefnum` Refnum of the Internet library.
- > `urlTextP` Pointer to URL text string.

<-> urlP            Pointer to address where the URL information block is to be returned.

### Result

0                            No error

inetErrParamsInvalid      urlTextP is NULL or empty, or urlP is NULL

inetErrURLVersionInvalid urlP is wrong version

### Comments

If a pointer member of urlP is set to NULL on entry, then on exit it will point to the start of that component within the original urlTextP string; the associated member length is set to the length of that URL component. If a pointer member of urlP is not NULL on entry, then it must point to a buffer of sufficient size to hold the member data, and on exit the component string will be copied into this buffer and the associated member length will be updated with the actual size. Note that the returned strings are not null-terminated, so the length values are important.

It's easiest to initialize the InetURLType block to zeros and let this function fill in all the information about the URL components.

The InetURLType block returned from this function has the following structure:

```
typedef struct {
    UInt16 version; // 0, for future compatibility
    UInt8 *schemeP; // ptr to scheme portion
    UInt16 schemeLen; // size of scheme portion
    UInt16 schemeEnum; // INetSchemeEnum; the scheme
    UInt8 *usernameP; // ptr to username portion
    UInt16 usernameLen; // size of username
    UInt8 *passwordP; // ptr to password portion
    UInt16 passwordLen; // size of password
    UInt8 *hostnameP; // ptr to host name portion
    UInt16 hostnameLen; // size of host name
    UInt16 port; // port number
    UInt8 *pathP; // ptr to path portion
    UInt16 pathLen; // size of path
}
```

## Internet Library

### Internet Library Functions

---

```
    UInt8 *paramP; // ptr to param (;param)
    UInt16 paramLen; // size of param
    UInt8 *queryP; // ptr to query (?query)
    UInt16 queryLen; // size of query
    UInt8 *fragP; // ptr to fragment (#frag)
    UInt16 fragLen; // size of fragment
} INetURLType
```

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## INetLibURLGetInfo

**Purpose** Returns information about a URL.

**Declared In** INetMgr.h

**Prototype** Err INetLibURLGetInfo (UInt16 libRefnum,  
MemHandle inetH, UInt8 \*urlTextP,  
INetURLInfoType \*urlInfoP)

**Parameters**

|              |                                                                           |
|--------------|---------------------------------------------------------------------------|
| -> libRefnum | Refnum of the Internet library.                                           |
| -> inetH     | Inet handle allocated by INetLibOpen.                                     |
| -> urlTextP  | Pointer to URL text string.                                               |
| <-> urlInfoP | Pointer to address where the URL information structure is to be returned. |

### Result

|                      |                                       |
|----------------------|---------------------------------------|
| 0                    | No error                              |
| inetErrParamsInvalid | urlInfoP is NULL or incorrect version |

**Comments** The InetURLInfo block returned from this function has the following structure:

```
typedef struct {
    UInt16 version; // 0, for future compatibility
    UInt16 flags; // flags word
}
```

```
UInt32 undefined; // reserved for future use
} INetURLInfo
```

The flags word can consist of some combination of these values:

```
inetURLInfoFlagIsSecure // URL was encrypted
inetURLInfoFlagIsRemote // URL was retrieved
from the net
inetURLInfoFlagIsInCache // URL is stored in
the cache
```

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

## **INetLibURLOpen**

**Purpose** Accesses a URL on the Internet or in the cache.

**Declared In** INetMgr.h

**Prototype**

```
Err INetLibURLOpen (UInt16 libRefnum,
MemHandle inetH, UInt8 *urlP,
UInt8 *cacheIndexURLP, MemHandle *sockHP,
Int32 timeout, UInt16 flags)
```

**Parameters**

- > libRefnum Refnum of the Internet library.
- > inetH Inet handle allocated by INetLibOpen.
- > urlP Pointer to string containing the URL to access.
- > cacheIndexURLP  
Pointer to URL string under which the requested URL should be indexed in the cache. Specify NULL if you don't need to index the cache. If you are using the Web Clipping Application Viewer cache (not recommended), you must follow the Viewer convention, which is to pass the URL of the active PQA.
- <- sockHP Pointer to address where the socket handle is returned.

## Internet Library

### Internet Library Functions

---

- > `timeout` Timeout in ticks. Specify `evtWaitForever` to wait forever.
- > `flags` Flags indicating caching and encryption options desired. Specify zero, one, or more of the URL open flags (see [URL Open Constants](#)).

#### Result

- 0 No error
- `inetErrParamsInvalid` `urlP` is NULL

**Comments** This call sets up a connection to a resource on the Internet addressed by `urlP` and returns a socket handle. Note that if you specify that the cache should be searched first, and if the data is found in the cache, no network I/O occurs. The application can then read that socket resource through the [INetLibSockRead](#) call.

This call is a convenience routine that internally makes the following calls for http URLs: [INetLibSockOpen](#), [INetLibSockConnect](#), [INetLibSockHTTPReqCreate](#), and [INetLibSockHTTPReqSend](#).

This routine returns immediately before performing any required network I/O. It is then up to the caller to either block on [INetLibSockRead](#), or to use [INetLibGetEvent](#) to model asynchronous operation. Using [INetLibGetEvent](#) is the preferred way of performing network I/O since it maximizes battery life and user-interface responsiveness.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

**See Also** [INetLibSockOpen](#), [INetLibSockConnect](#), [INetLibSockRead](#), [INetLibSockClose](#)

## INetLibURLsAdd

**Purpose** Concatenates two URLs, resulting in one absolute URL.

**Declared In** `INetMgr.h`

### INetLibWiCmd

- Purpose** Invokes a command that operates on the wireless indicator.
- Declared In** `INetMgr.h`
- Prototype** `Boolean INetLibWiCmd (UInt16 refNum, UInt16 cmd, int enableOrX, int y)`
- Parameters**
- > `refNum` Refnum of the Internet library.
  - > `cmd` The command to invoke. Specify one of the `WiCmdEnum` values (see Comments section).
  - > `enableOrX` If `cmd` is `wiCmdSetEnabled`, specify 1 to enable the wireless indicator or 0 to disable it. If `cmd` is `wiCmdSetLocation`, this specifies the x coordinate of the location.
  - > `y` The y coordinate of the location. Used only if `cmd` is `wiCmdSetLocation`.
- Result** If `cmd` is `wiCmdEnabled`, this function returns `true` if the wireless indicator is enabled or `false` if it is not. For other command types, the return value is undefined.
- Comments** The wireless indicator is a 19x13 pixel image on the screen to indicate the current wireless signal strength. This shows as 0 - 5 bars. If the application is in a non-modal window with a title bar, the preferred location for the indicator is at (140,1).
- It automatically updates itself as long as you are calling `INetLibGetEvent`. It should be shown on screen while a wireless transaction is in progress. It may also be shown when the user has nothing useful to do next but initiate a wireless transaction, and there isn't much other useful information being displayed.
- The `WiCmdEnum` enum specifies a command that operates on the wireless indicator in the user interface. The definition of this type is found in `WirelessIndicator.h` and is as follows:

```
typedef enum {  
    wiCmdInit = 0,  
    ...  
};
```

```
wiCmdClear,  
wiCmdSetEnabled,  
wiCmdDraw,  
wiCmdEnabled,  
wiCmdSetLocation,  
wiCmdErase  
} WiCmdEnum;
```

### Value Descriptions

|                               |                                                                                                                                                                                             |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>wiCmdInit</code>        | Initializes the wireless indicator. You must invoke this command first, before using any of the others.                                                                                     |
| <code>wiCmdClear</code>       | Applications shouldn't use this command. To erase the indicator, disable it by using <code>wiCmdSetEnabled</code> and passing 0 for <code>enableOrX</code> .                                |
| <code>wiCmdSetEnabled</code>  | Enables or disables the wireless indicator.                                                                                                                                                 |
| <code>wiCmdDraw</code>        | Redraws the wireless indicator using the latest data. Applications don't need to use this command since the indicator is redrawn automatically by <code>INetLibGetEvent</code> .            |
| <code>wiCmdEnabled</code>     | Returns a Boolean indicating if the wireless indicator is enabled.                                                                                                                          |
| <code>wiCmdSetLocation</code> | Sets the location for the wireless indicator on the screen.                                                                                                                                 |
| <code>wiCmdErase</code>       | Erases the wireless indicator. Applications shouldn't use this command. To erase the indicator, disable it by using <code>wiCmdSetEnabled</code> and passing 0 for <code>enableOrX</code> . |

**Compatibility**    Implemented only if [Wireless Internet Feature Set](#) is present.

## **Internet Library**

*Internet Library Functions*

---

# PalmOSGlue Library

---

This chapter describes the API provided in the link library PalmOSGlue (PalmOSGlue.lib or libPalmOSGlue.a).

You use PalmOSGlue if you want to use the international and text manager features described in the chapter “[Localized Applications](#)” on page 363 in the *Palm OS Programmer’s Companion*, vol. I and you want to maintain backward compatibility with earlier releases of Palm OS®. If you link with PalmOSGlue, include the headers in the folder `Incs\Libraries\PalmOSGlue`, and make calls as they are listed in this chapter, then your code will run regardless of whether the device’s version of the operating system implements international support. The code in PalmOSGlue either uses the text manager or international manager on the ROM or, if the managers don’t exist, executes a simple Latin equivalent of the function.

---

**NOTE:** PalmOSGlue is a link library, not a shared library. Linking with this library increases your application’s code size. The amount by which your code size increases varies depending on the number of library functions you call. Use PalmOSGlue only on versions 2.0 and later of Palm OS.

---

In addition to covering the text and international manager API, PalmOSGlue adds some functions that are not included in any version of the Palm OS. This chapter describes the functions that are unique to PalmOSGlue and provides a mapping of PalmOSGlue calls to calls that exist in later versions of Palm OS.

## PalmOSGlue Functions

The following table shows the mapping between the functions declared in the glue headers and the international functions and macros. To learn more about a glue function, click the link in the right column.

This table lists only those functions that map to a function that exists in newer versions of the OS. The functions that are exclusive to PalmOSGlue are not listed. They are described following this table.

**Table 75.1 PalmOSGlue function mappings**

| <b>This PalmOSGlue function...</b> | <b>...is identical to...</b>        |
|------------------------------------|-------------------------------------|
| BmpGlueGetBitDepth                 | <a href="#">BmpGetBitDepth</a>      |
| BmpGlueGetDimensions               | <a href="#">BmpGetDimensions</a>    |
| BmpGlueGetNextBitmap               | <a href="#">BmpGetNextBitmap</a>    |
| DateGlueTemplateToAscii            | <a href="#">DateTemplateToAscii</a> |
| DateGlueToDOWDMFormat              | <a href="#">DateToDOWDMFormat</a>   |
| FntGlueWCharWidth                  | <a href="#">FntWCharWidth</a>       |
| FntGlueWidthToOffset               | <a href="#">FntWidthToOffset</a>    |
| LmGlueGetLocaleSetting             | <a href="#">LmGetLocaleSetting</a>  |
| LmGlueGetNumLocales                | <a href="#">LmGetNumLocales</a>     |
| LmGlueLocaleToIndex                | <a href="#">LmLocaleToIndex</a>     |
| LstGlueGetTopItem                  | <a href="#">LstGetTopItem</a>       |
| OmGlueGetCurrentLocale             | <a href="#">OmGetCurrentLocale</a>  |
| OmGlueGetSystemLocale              | <a href="#">OmGetSystemLocale</a>   |

---

## BmpGlueGetCompressionType

- Purpose** Returns the compression type used for a specified bitmap.
- Declared In** `BmpGlue.h`
- Prototype**

```
BitmapCompressionType BmpGlueGetCompressionType  
(const BitmapType *bitmapP)
```
- Parameters** `-> bitmapP` Pointer to the bitmap.
- Result** Returns a `BitmapCompressionType` enum value. If `bitmapP` is `NULL`, or the specified bitmap is not compressed, this function returns `BitmapCompressionTypeNone`. If the specified bitmap's encoding version is less than 2, this function returns `BitmapCompressionTypeScanLine`.
- See Also** `BmpCompress`

## BmpGlueGetTransparentValue

- Purpose** Indicates if a specified bitmap has transparency—if, when the bitmap is drawn, pixels of a certain value won't be drawn.
- Declared In** `BmpGlue.h`
- Prototype**

```
Boolean BmpGlueGetTransparentValue  
(const BitmapType *bitmapP,  
UInt32 *transparentValueP)
```
- Parameters** `-> bitmapP` Pointer to the bitmap.

`<- transparentValueP`

The pixel value that isn't drawn, if the bitmap has transparency. If the value returned by `BmpGlueGetTransparentValue` is false, `*transparentValueP` is left unchanged.

**Result** Returns `true` if, when drawing the specified bitmap, Palm OS doesn't draw pixels that have a value equal to that returned in `transparentValueP`. Returns `false` if all pixels are drawn.

**Comments** You can specify the transparent color when you create the bitmap using Constructor.

**See Also** [BmpGlueSetTransparentValue](#)

### **BmpGlueSetTransparentValue**

**Purpose** Causes pixels of a specified color not to be drawn when the bitmap is drawn.

**Declared In** `BmpGlue.h`

**Prototype** `void BmpGlueSetTransparentValue  
(BitmapType *bitmapP, UInt32 transparentValue)`

**Parameters** `-> bitmapP` Pointer to the bitmap.  
`-> transparentValueP` The pixel value that isn't drawn.

**Result** Returns nothing.

**Comments** Does nothing if `bitmapP` is `NULL`, if `bitmapP` is an off-screen bitmap, or if `transparentValue` is invalid given the bitmap's bit depth.

If the specified bitmap's encoding version is less than 2, this function updates it to 2.

**See Also** [BmpGlueGetTransparentValue](#)

## CtlGlueGetControlStyle

- Purpose** Return the type of the control, such as button, slider, and so on.
- Declared In** `CtlGlue.h`
- Prototype** `ControlStyleType CtlGlueGetControlStyle  
(const ControlType *ctlP)`
- Parameters** `-> ctlP` A pointer to a [ControlType](#) structure.
- Result** Returns one of the [ControlStyleType](#) constants.
- Compatibility** Implemented only in the PalmOSGlue library.

## CtlGlueGetFont

- Purpose** Gets the font used when drawing a specified control's label.
- Declared In** `CtlGlue.h`
- Prototype** `FontID CtlGlueGetFont (const ControlType *ctlP)`
- Parameters** `-> ctlP` Pointer to the control object.
- Result** Returns the ID of the font used to draw the control's label.
- See Also** [CtlGlueSetFont](#)

## **CtlGlueGetGraphics**

**Purpose** Gets the bitmaps displayed in place of a specified control's label.

**Declared In** `CtlGlue.h`

**Prototype** `void CtlGlueGetGraphics (const ControlType *ctlP,  
DmResID *bitmapID, DmResID *selectedBitmapID)`

**Parameters**

- > `ctlP` Pointer to the control.
- <- `bitmapID` Resource ID of the bitmap to display when the graphical control is not selected.
- <- `selectedBitmapID` Resource ID of the bitmap to display when the graphical control is selected, if, when selected, the graphical control should show a different bitmap.

**Result** Returns nothing.

**Comments** If the specified control is not a graphical control—one that displays a bitmap in place of the text label—`*bitmapID` and `*selectedBitmapID` are set to zero.

This function works with any graphical control, including sliders.

**Compatibility** Implemented only if 3.5 New Feature Set is present.

**See Also** [CtlGlueGetFont](#), [CtlSetGraphics](#)

## CtlGlueNewSliderControl

- Purpose** Create a new slider or feedback slider dynamically and install it in the specified form. The newly-created control is marked as a graphical control.
- Declared In** CtlGlue.h
- Prototype**

```
SliderControlType *CtlGlueNewSliderControl  
(void **formPP, UInt16 ID,  
ControlStyleType style, DmResID thumbID,  
DmResID backgroundID, Coord x, Coord y,  
Coord width, Coord height, UInt16 minValue,  
UInt16 maxValue, UInt16 pageSize, UInt16 value)
```
- Parameters**
- <-> formPP Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the formPP value may change if the object moves in memory. In subsequent calls, always use the new formPP value returned by this function.
  - > ID Symbolic ID of the slider.
  - > style Either sliderCtl or feedbackSliderCtl. See ControlStyleType.
  - > thumbID Resource ID of the bitmap to display as the slider thumb. The slider thumb is the knob that the user can drag to change the slider's value. To use the default thumb bitmap, pass NULL for this parameter.
  - > backgroundID Resource ID of the bitmap to display as the slider background. To use the default background bitmap, pass NULL for this parameter.
  - > x Horizontal coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.

## PalmOSGlue Library

### *PalmOSGlue Functions*

---

|                          |                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------|
| -> <code>y</code>        | Vertical coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears. |
| -> <code>width</code>    | Width of the slider, expressed in pixels. Valid values are 1–160.                                                    |
| -> <code>height</code>   | Height of the slider, expressed in pixels. Valid values are 1–160.                                                   |
| -> <code>minValue</code> | Value of the slider when its thumb is all the way to the left.                                                       |
| -> <code>maxValue</code> | Value of the slider when its thumb is all the way to the right.                                                      |
| -> <code>pageSize</code> | Amount by which to increase or decrease the slider's value when the user clicks to the right or left of the thumb.   |
| -> <code>value</code>    | The initial value to display in the slider.                                                                          |

**Result** Returns a pointer to the new slider control. See `SliderControlType`.

**Compatibility** Implemented only if 3.5 New Feature Set is present.

**See Also** `CtlNewSliderControl`, `CtlNewGraphicControl`, `CtlNewControl`, `CtlValidatePointer`, `FrmRemoveObject`

## **CtlGlueSetFont**

**Purpose** Sets the font to use when drawing the control's label.

**Declared In** `CtlGlue.h`

**Prototype** `void CtlGlueSetFont (ControlType *ctlP, FontID fontID)`

**Parameters** -> `ctlP` Pointer to the control object.

-> fontID            The ID of the font to use when drawing the control's label.

**Result**            Returns nothing.

**See Also**          [CtlGlueGetFont](#)

## **CtlGlueSetLeftAnchor**

**Purpose**            Causes a control's left bound to be fixed or to float.

**Declared In**      CtlGlue.h

**Prototype**        void CtlGlueSetLeftAnchor (ControlType \*ctlP,  
                              Boolean leftAnchor)

**Parameters**      -> ctlP            Pointer to the control.  
                     -> leftAnchor    A value of true causes the left bound of the control to be fixed.

**Result**            Returns nothing.

**Comments**        Used by controls that expand and shrink their width when the label is changed.

## **FldGlueGetLineInfo**

**Purpose**            Retrieve the word-wrapping information for a visible line within a field.

**Declared In**      FldGlue.h

**Prototype**        Boolean FldGlueGetLineInfo  
                     (const FieldType \*fldP, UInt16 lineNum,  
                     UInt16 \*startP, UInt16 \*lengthP)

**Parameters**      -> fldP            A pointer to a [FieldType](#) structure.

## PalmOSGlue Library

### PalmOSGlue Functions

---

|                         |                                                                                                                                                                                                          |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>lineNum</code> | The number of the visible line in the field about which you want to retrieve information. Lines are numbered starting at 0.                                                                              |
| <- <code>startP</code>  | The byte offset into the <code>FieldType</code> 's text field of the first character displayed by this line. If the line is blank, <code>start</code> is equal to the length of the field's text string. |
| <- <code>lengthP</code> | The length in bytes of the portion of the string displayed on this line. If the line is blank, the length is 0.                                                                                          |

**Result** Returns `true` if `startP` and `endP` contain valid values, or `false` if the field is a single-line field or does not contain a line numbered `lineNum`.

**Compatibility** Implemented only in the PalmOSGlue library.

## FntGlueGetDefaultFontID

**Purpose** Return the font ID of a default font.

**Declared In** `FntGlue.h`

**Prototype** `FontID FntGlueGetDefaultFontID (FontDefaultType inFontType)`

**Parameters** -> `inFontType` A `FontDefaultType` constant specifying one of the system default fonts. This value can be one of the following:

`defaultSystemFont`  
The default font for the system.

`defaultLargeFont`  
The default large font.

`defaultSmallFont`  
The default small font.

`defaultBoldFont`  
The default bold font.

**Result** Returns the ID of `inFontType`.

**Comments** Use this function whenever you need to obtain a font ID for one of the system default fonts. The default fonts (and thus, the IDs for the default fonts) vary depending on the system's locale. For example, Japanese systems have a different set of default fonts than systems using the Latin character encoding.

Use this function in place of the constants that specify the IDs of default fonts, as shown in the following table.

---

| In place of this... | ...use <code>FntGlueGetDefaultFontID</code> with this constant... |
|---------------------|-------------------------------------------------------------------|
|---------------------|-------------------------------------------------------------------|

---

|                            |                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <code>stdFont</code>       | <code>defaultSystemFont</code> (best for displaying text) or:<br><code>defaultSmallFont</code> (if you want a smaller font) |
| <code>largeFont</code>     | <code>defaultLargeFont</code>                                                                                               |
| <code>largeBoldFont</code> | <code>defaultLargeFont</code>                                                                                               |
| <code>boldFont</code>      | <code>defaultBoldFont</code>                                                                                                |

---

Note that `defaultSystemFont` and `defaultSmallFont` might return the same font ID or different font IDs, depending on the system locale.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [FontSelect](#), [FntGetFont](#), [FntSetFont](#)

## **FrmGlueGetActiveField**

- Purpose** Return the active field for a form.
- Declared In** FrmGlue.h
- Prototype** extern FieldType \*FrmGlueGetActiveField  
(const FormType \*formP)
- Parameters** -> formP            Pointer to the form, or NULL to use the active form.
- Result** Returns a pointer to the active field. Returns NULL if there is no active form or field.

## **FrmGlueGetDefaultButtonID**

- Purpose** Gets the resource ID of the object on the form defined as the default button.
- Declared In** FrmGlue.h
- Prototype** UInt16 FrmGlueGetDefaultButtonID  
(const FormType \*formP)
- Parameters** -> formP            Pointer to the form.
- Result** Returns the resource ID of the object defined as the default button.
- See Also** FrmDoDialog, [FrmGlueSetDefaultButtonID](#)

## FrmGlueGetHelpID

- Purpose** Gets the resource ID number of the form's help resource.
- Declared In** `FrmGlue.h`
- Prototype** `UInt16 FrmGlueGetHelpID (const FormType *formP)`
- Parameters** `-> formP` Pointer to the form.
- Result** Returns the resource ID number of the form's help resource. The help resource is a String resource (type 'tSTR').
- See Also** [FrmGlueSetHelpID](#)

## FrmGlueGetLabelFont

- Purpose** Gets the font used for a particular label that appears on a form.
- Declared In** `FrmGlue.h`
- Prototype** `FontID FrmGlueGetLabelFont (const FormType *formP, UInt16 labelID)`
- Parameters** `-> formP` Pointer to the form.  
`-> labelID` ID of a label object in the form (the object's type must be `frmLabelObj`).
- Result** Returns a `FontID` value of 0 if either `labelID` is invalid or if the object indicated by `labelID` has a type other than `frmLabelObj`. Otherwise, this function returns the ID of the font used for the label.
- See Also** `FrmGetObjectType`, [FrmGlueSetLabelFont](#)

## **FrmGlueGetMenuBarID**

- Purpose** Gets the ID number of the form's menu bar.
- Declared In** `FrmGlue.h`
- Prototype**  
`UInt16 FrmGlueGetMenuBarID  
(const FormType *formP)`
- Parameters** `-> formP` Pointer to the form.
- Result** Returns the ID number of the form's menu bar, or zero if the form doesn't have a menu bar.
- See Also** `FrmSetMenu`

## **FrmGlueGetObjectUsable**

- Purpose** Returns whether an object in a form has been hidden.
- Declared In** `FrmGlue.h`
- Prototype**  
`Boolean  
FrmGlueGetObjectUsable (const FormType *formP,  
UInt16 objIndex)`
- Parameters** `-> formP` A pointer to a [FormType](#) structure.  
`-> objIndex` The index of the object on the form.
- Result** Returns `true` if the object is usable, meaning that it is considered part of the user interface. Returns `false` if the object is not usable. Objects that are not usable never appear on the screen. The function [FrmHideObject](#) clears an object's usable bit to hide that the object.
- Comments** Implemented only in the PalmOSGlue library.

## FrmGlueSetDefaultButtonID

- Purpose** Designates the object on the form that is to act as the default button.
- Declared In** FrmGlue.h
- Prototype** void FrmGlueSetDefaultButtonID (FormType \*formP,  
UInt16 defaultButton)
- Parameters**
- > formP Pointer to the form.
  - > defaultButton The resource ID of the object on the form that is to be the default button.
- Result** Returns nothing.
- See Also** FrmDoDialog, [FrmGlueGetDefaultButtonID](#)

## FrmGlueSetHelpID

- Purpose** Designates the String resource that is to act as the form's help resource.
- Declared In** FrmGlue.h
- Prototype** void FrmGlueSetHelpID (FormType \*formP,  
UInt16 helpRscID)
- Parameters**
- > formP Pointer to the form.
  - > helpRscID The resource ID of the String resource that is to be the form's help resource.
- Result** Returns nothing.
- See Also** [FrmGlueGetHelpID](#)

## **FrmGlueSetLabelFont**

- Purpose** Sets the font used for a particular label that appears on a form.
- Declared In** FrmGlue.h
- Prototype** void FrmGlueSetLabelFont (FormType \*formP,  
UInt16 labelID, FontID fontID)
- Parameters**
- > formP Pointer to the form.
  - > labelID ID of a label object in the form (the object's type must be frmLabelObj).
  - > fontID ID of the font to be used for the label.
- Result** Returns nothing.
- Comments** This function does nothing if either labelID is invalid or if the object indicated by labelID has a type other than frmLabelObj.
- See Also** FrmGetObjectType, [FrmGlueGetLabelFont](#)

## **IntlGlueGetRoutineAddress**

- Purpose** Return the address of a Text Manager function or of its PalmOSGlue equivalent.
- Declared In** IntlGlue.h
- Prototype** void \*IntlGlueGetRoutineAddress  
(IntlSelector selector, const void \*latinSymbol)
- Parameters**
- > selector One of the routine selectors defined in IntlMgr.h.

-> latinSymbol    The corresponding *TxtLatinfunc* symbol defined in *IntlGlue.h*.

**Result**    Returns the address of the native Palm OS function if it is defined. If the function is not defined, it returns the address of the corresponding PalmOSGlue function.

**Comments**    Use *IntlGlueGetRoutineAddress* for performance reasons. You can use the address that it returns to call the function at that address without having to go through the International Manager's trap dispatch table. *IntlGlueGetRoutineAddress* is mostly useful for optimizing the performance of Text Manager functions that are called in a tight loop.

To call *IntlGlueGetRoutineAddress*, you must pass both the international trap for the function and the corresponding symbol. For example, to obtain the address of the *TxtGetNextChar* function or of its PalmOSGlue equivalent, you would make this call:

```
myTxtGetNextChar =  
    IntlGlueGetRoutineAddress (intlTxtGetNextChar,  
                               TxtLatinGetNextChar);
```

The returned address is only valid while your application stays locked in memory. For this reason, you should only use the returned address up to the point where your application terminates. When the application starts up again, you should call *IntlGlueGetRoutineAddress* again.

**Compatibility**    Implemented only in the PalmOSGlue library.

**See Also**    [\*IntlGetRoutineAddress\*](#)

## **LstGlueGetFont**

**Purpose** Get the font used to draw a list's text strings.

**Declared In** `LstGlue.h`

**Prototype** `FontID LstGlueGetFont (const ListType *listP)`

**Parameters** `-> listP` Pointer to the list.

**Result** Returns the ID of the font used to draw all list text strings.

**See Also** [LstGlueSetFont](#)

## **LstGlueGetItemsText**

**Purpose** Get the text strings that represent the items in a list.

**Declared In** `LstGlue.h`

**Prototype** `Char **LstGlueGetItemsText  
(const ListType *listP)`

**Parameters** `-> listP` Pointer to the list.

**Result** Returns a pointer to an array of pointers to the text of the list choices.

**See Also** `LstGetSelectionText`, `LstSetListChoices`

## LstGlueSetFont

- Purpose** Specify the font to be used to draw a list's text strings.
- Declared In** `LstGlue.h`
- Prototype**  
`void LstGlueSetFont (ListType *listP,  
FontID fontID)`
- Parameters**
- > `listP` Pointer to the list.
  - > `fontID` ID of the font to be used to draw all list text strings.
- Result** Returns nothing.
- See Also** [LstGlueGetFont](#)

## LstGlueSetIncrementalSearch

- Purpose** Enables or disables incremental search for a sorted popup list.
- Declared In** `LstGlue.h`
- Prototype**  
`void LstGlueSetIncrementalSearch  
(ListType *listP, Boolean incrementalSearch)`
- Parameters**
- > `listP` Pointer to the list.
  - > `incrementalSearch` Set to true to enable incremental search, false to disable it.
- Result** Returns nothing.
- Comments** If incremental search is enabled, when the list is displayed the user can navigate the list by entering up to five characters. The list will scroll to present the first list item that matches the entered characters. This feature only works for popup lists, and only works

if the list is sorted and the list items are available to the List Manager (that is, you don't pass `NULL` to `LstSetListChoices`).

## **SysGlueTrapExists**

**Purpose** Macro that indicates if a given trap exists on the current system.

**Declared In** `SysGlue.h`

**Prototype** `SysGlueTrapExists (trapNum)`

**Parameters** `-> trapNum` One of the system trap constants.

**Result** Returns `true` if the current operating system defines the system trap `trapNum`, or `false` if the trap does not exist on that version of the operating system.

**Compatibility** Implemented only in the PalmOSGlue library.

## **TblGlueGetColumnMasked**

**Purpose** Determines whether a particular table column is masked.

**Declared In** `TblGlue.h`

**Prototype** `Boolean TblGlueGetColumnMasked  
(const TableType *tableP, Int16 column)`

**Parameters** `-> tableP` Pointer to the table.  
`-> column` Column number (zero-based).

**Result** Returns `true` if the column is masked, `false` otherwise.

**Comments** If a table cell's column is masked and the cell's row is also masked, the table cell is drawn on the screen but is shaded to obscure the information that it contains.

**See Also** `TblSetColumnMasked`

## **TxtGlueCharIsVirtual**

**Purpose** Return whether a character is a virtual character or not.

**Declared In** `TxtGlue.h`

**Prototype** `Boolean TxtGlueCharIsVirtual (UInt16 inModifiers, WChar inChar)`

**Parameters**

- > `inModifiers` The value passed in the `modifiers` field of the [keyDownEvent](#).
- > `inChar` A character.

**Result** Returns `true` if the character `inChar` is a virtual character, `false` otherwise.

**Comments** Virtual characters are nondisplayable characters that trigger special events in the operating system, such as displaying low battery warnings or displaying the keyboard dialog. Virtual characters should never occur in any data and should never appear on the screen.

Starting in Palm OS 3.1, the command modifier bit is always set in the `keyDownEvent` for a virtual character because the range for virtual characters overlaps the range for "real" characters that should appear on the screen. Earlier releases of the operating system did not always set the command modifier for virtual characters.

You can use this function to test whether a character is virtual or not. Pass the `chr` and `modifiers` fields exactly as you received them in the [keyDownEvent](#), and this function performs the appropriate check based on the operating system version.

**Compatibility** Implemented only in the PalmOSGlue library.

### **TxtGlueFindString**

**Purpose** Perform a case-insensitive search for a string in another string.

**Declared In** `TextMgr.h`

**Prototype**

```
Boolean TxtGlueFindString
(const Char *inSourceStr,
const Char *inTargetStr, UInt32 *outPos,
UInt16 *outLength)
```

**Parameters**

- > `inSourceStr` Pointer to the string to be searched.
- > `inTargetStr` Prepared version of the string to be found. This string should either be passed directly from the `strToFind` field in the [sysAppLaunchCmdFind](#) launch code's parameter block or it should be prepared using [TxtGluePrepFindString](#).
- <- `outPos` Pointer to the offset of the match in `inSourceStr`.
- <- `outLength` Pointer to the length in bytes of the matching text.

**Result** Returns `true` if the function finds `inTargetStr` within `inSourceStr`; `false` otherwise.

If found, the values pointed to by the `outPos` and `outLength` parameters are set to the starting offset and the length of the matching text. Unlike [TxtFindString](#), if the target string is not found, the values pointed to by `outPos` and `outLength` are not necessarily set to 0.

The search that `TxtGlueFindString` performs is locale-dependent. On most ROMs with Latin-based encodings, `TxtGlueFindString` returns `true` only if the string is at the beginning of a word. On Shift-JIS encoded ROMs,

`TxtGlueFindString` returns `true` if the string is located anywhere in the word.

**Comments** Use this function instead of [FindStrInStr](#) to support the global system find facility. This function contains an extra parameter, `outLength`, to specify the length of the text that matched. Pass this value to [FindSaveMatch](#) in the `appCustom` parameter. Then when your application receives `sysAppLaunchCmdGoTo`, the `matchCustom` field contains the length of the matching text. You use the length of matching text to highlight the match within the selected record.

You must make sure that the parameters `inSourceStr` and `inTargetStr` point to the start of a valid character. That is, they must point to the first byte of a multi-byte character, or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [TxtFindString](#), [TxtCaselessCompare](#)

## **TxtGlueGetHorizEllipsisChar**

**Purpose** Return the horizontal ellipsis character.

**Declared In** `TxtGlue.h`

**Prototype** `WChar TxtGlueGetHorizEllipsisChar (void)`

**Parameters** None.

**Result** Returns the character code for horizontal ellipsis.

**Comments** Versions 3.1 and higher of the Palm OS use different character codes for the horizontal ellipsis character and the numeric space character than earlier versions did. Use `TxtGlueGetHorizEllipsisChar` to return the appropriate code for horizontal ellipsis regardless of which version of Palm OS your application is run on.

## PalmOSGlue Library

### *PalmOSGlue Functions*

---

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [ChrHorizEllipsis](#), [TxtGlueGetNumericSpaceChar](#)

## **TxtGlueGetNumericSpaceChar**

**Purpose** Return the numeric space character.

**Declared In** `TxtGlue.h`

**Prototype** `WChar TxtGlueGetNumericSpaceChar (void)`

**Parameters** None.

**Result** Returns the character code for numeric space.

**Comments** Versions 3.1 and higher of the Palm OS use different character codes for the horizontal ellipsis character and the numeric space character than earlier versions did. Use `TxtGlueGetNumericSpaceChar` to return the appropriate code for numeric space regardless of which version of Palm OS your application is run on.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [ChrNumericSpace](#), [TxtGlueGetHorizEllipsisChar](#)

## **TxtGlueLowerChar**

**Purpose** Convert a character to lowercase.

**Declared In** `TxtGlue.h`

**Prototype** `WChar TxtGlueLowerChar (WChar inChar)`

**Parameters** `-> inChar` A character.

**Result** Returns the character as a lowercase letter.

**Comments** This function does not handle the case in which the lowercase version of a character is represented by two or more characters. If you need to handle this situation, call the [TxtGlueLowerStr](#) function instead of this one.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [TxtGlueUpperChar](#), [TxtGlueLowerStr](#), [TxtGlueUpperStr](#), [TxtGlueTransliterate](#), [TxtTransliterate](#), [StrToLower](#)

## **TxtGlueLowerStr**

**Purpose** Convert a string to all lowercase letters.

**Declared In** `TxtGlue.h`

**Prototype** `void TxtGlueLowerStr (Char* ioString,  
UInt16 inMaxLength)`

**Parameters**

|                                 |                                                                                            |
|---------------------------------|--------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; ioString</code> | The string to be converted.                                                                |
| <code>-&gt; inMaxLength</code>  | The size of the buffer that contains the string, excluding the terminating null character. |

**Result** Returns in `ioString` the input string with its letters converted to lowercase.

**Comments** Converting a string from uppercase to lowercase letters or vice versa may change the size of the string. For this reason, you should always check the size of the `ioString` after this call returns.

You must make sure that the parameter `ioString` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.

This function can only handle characters in the ISO Latin 1 character encoding unless the [International Feature Set](#) is present.

## PalmOSGlue Library

### *PalmOSGlue Functions*

---

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [TxtGlueUpperStr](#), [TxtGlueLowerChar](#), [TxtGlueUpperChar](#), [StrToLower](#) [TxtGlueTransliterate](#), [TxtTransliterate](#)

## TxtGluePrepFindString

**Purpose** Set up for [TxtFindString](#) or [FindStrInStr](#).

**Declared In** `TxtGlue.h`

**Prototype** `void TxtGluePrepFindString (const Char* inSource, CharPtr outDest, UInt16 inDstSize)`

**Parameters**

|              |                                                                                                                                  |
|--------------|----------------------------------------------------------------------------------------------------------------------------------|
| -> inSource  | Pointer to the text to be searched for. Must not be NULL.                                                                        |
| <- outDest   | The same text as in inSource but converted to a suitable format for searching. outDest must not be the same address as inSource. |
| -> inDstSize | The length in bytes of the area pointed to by outDest.                                                                           |

**Result** Returns in outDest an appropriately converted string.

**Comments** Use this function to normalize the string to search for before using `TxtGlueFindString`, `TxtFindString`, or `FindStrInStr` to perform a search that is internal to your application. If you use any of these three search routines in response to the [sysAppLaunchCmdFind](#) launch code, the string that the launch code passes in is already properly normalized for the search.

This function normalizes the string to be searched for. The method by which a search string is normalized varies depending on the version of Palm OS and the character encoding supported by the device.

Only inDstSize bytes of inSource are written to outDest. If necessary to prevent overflow of the destination buffer, not all of inSource is converted.

You must make sure that the parameter `inSource` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.

**Compatibility** Implemented only in the PalmOSGlue library.

## **TxtGlueStripSpaces**

**Purpose** Strip trailing and/or leading spaces from a string.

**Declared In** `TxtGlue.h`

**Prototype** `Char* TxtGlueStripSpaces (Char* ioStr, Boolean leading, Boolean trailing)`

**Parameters**

|                              |                                                                   |
|------------------------------|-------------------------------------------------------------------|
| <code>&lt;-&gt; ioStr</code> | Any string.                                                       |
| <code>-&gt; leading</code>   | If <code>true</code> , strip the leading spaces from the string.  |
| <code>-&gt; trailing</code>  | If <code>true</code> , strip the trailing spaces from the string. |

**Result** Returns `ioStr` with the specified spaces stripped from it. Note that this function both changes the `ioStr` buffer parameter and returns a pointer to it.

**Comments** You must make sure that the parameter `ioStr` points to the start of a a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.

**Compatibility** Implemented only in the PalmOSGlue library.

## **TxtGlueTruncateString**

**Purpose** Determine if a string can be displayed in a given number of pixels. If not, truncate the string.

**Declared In** `TxtGlue.h`

**Prototype** `Boolean TxtGlueTruncateString (Char *ioStringP, UInt16 inMaxWidth)`

**Parameters**

|                                  |                                                                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; ioStringP</code> | A null-terminated string. Upon return, the string is truncated if necessary so that it can be displayed in <code>inMaxWidth</code> pixels. |
| <code>-&gt; inMaxWidth</code>    | The maximum width in pixels.                                                                                                               |

**Result** Returns `true` if the string was truncated, or `false` if the string can fit without truncation.

**Comments** This function determines whether `ioStringP` can be displayed in the specified width without being truncated. If it can, `TxtGlueTruncateString` returns `false`. If the string must be truncated, this function truncates the string to one less than the number of characters that can fit in `inMaxWidth` and then appends an ellipsis (...) character. (If the boundary characters are narrower than the ellipsis, more than one character may be dropped to make room). If `inMaxWidth` is narrower than the width of an ellipsis, the string is set to the empty string.

**Compatibility** Implemented only in the PalmOSGlue library.

**See Also** [FntWidthToOffset](#), [WinDrawTruncChars](#), [TxtGetTruncationOffset](#)

## TxtGlueUpperChar

|                      |                                                                                                                                                                                                                                             |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Convert a character to uppercase.                                                                                                                                                                                                           |
| <b>Declared In</b>   | <code>TxtGlue.h</code>                                                                                                                                                                                                                      |
| <b>Prototype</b>     | <code>WChar TxtGlueUpperChar (WChar inChar)</code>                                                                                                                                                                                          |
| <b>Parameters</b>    | -> <code>inChar</code> Any character.                                                                                                                                                                                                       |
| <b>Result</b>        | Returns the character as an uppercase letter.                                                                                                                                                                                               |
| <b>Comments</b>      | This function does not handle the case in which the uppercase version of a character is represented by two or more characters. If you need to handle this situation, call the <a href="#">TxtGlueUpperStr</a> function instead of this one. |
| <b>Compatibility</b> | Implemented only in the PalmOSGlue library.                                                                                                                                                                                                 |
| <b>See Also</b>      | <a href="#">TxtGlueLowerChar</a> , <a href="#">TxtGlueUpperStr</a> <a href="#">TxtGlueLowerStr</a> , <a href="#">TxtGlueTransliterate</a> , <a href="#">TxtTransliterate StrToLower</a>                                                     |

## **TxtGlueUpperStr**

- Purpose** Convert a string to all uppercase letters.
- Declared In** `TxtGlue.h`
- Prototype** `void TxtGlueUpperStr (Char* ioString, UInt16 inMaxLength)`
- Parameters**
- `<-> ioString` The string to be converted.
  - `-> inMaxLength` The size of the buffer that contains the string, excluding the terminating null character.
- Result** Returns in `ioString` the input string with its letters converted to uppercase.
- Comments**
- Converting a string from uppercase to lowercase letters or vice versa may change the size of the string. For this reason, you should always check the size of the `ioString` after this call returns.
- You must make sure that the parameter `ioString` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character. If it doesn't, results are unpredictable.
- This function can only handle characters in the ISO Latin 1 character encoding unless the [International Feature Set](#) is present.
- Compatibility** Implemented only in the PalmOSGlue library.
- See Also** [TxtGlueLowerStr](#), [TxtGlueUpperChar](#), [TxtGlueLowerChar](#), [TxtGlueTransliterate](#), [TxtTransliterate StrToLower](#)

## WinGlueGetFrameType

- Purpose** Gets the frame type for a specified window.
- Declared In** WinGlue.h
- Prototype** `FrameType WinGlueGetFrameType  
(const WinHandle winH)`
- Parameters** -> winH            The window's handle.
- Result** Returns a FrameType value indicating the window's frame style.
- See Also** [WinGlueSetFrameType](#)

## WinGlueSetFrameType

- Purpose** Sets the type of frame to be used for a specified window.
- Declared In** WinGlue.h
- Prototype** `void WinGlueSetFrameType (WinHandle winH,  
FrameType frame)`
- Parameters** -> winH            The window's handle.  
              -> frame            The style of frame to be used.
- Result** Returns nothing.
- See Also** [WinGlueGetFrameType](#)

## **PalmOSGlue Library**

*PalmOSGlue Functions*

---

# Bluetooth Library: General Functions

---

The Bluetooth library is a shared library that provides a direct interface to the Bluetooth communication capability of the Palm OS. This chapter presents reference material for the security and utility functions of the Bluetooth library API:

[Security Functions](#) Describes security functions that allow the application to manage a database of trusted devices. Trusted devices don't need to undergo authentication when they reconnect with the local device.

[Utility Functions](#) Describes utility functions and macros that are useful when working with the Bluetooth library. They perform such tasks as converting between host and network byte ordering, and converting between device addresses and strings.

The header file `BtLib.h` declares the Bluetooth library functions and macros. The header file `BtLibTypes.h` declares the data structures that you use with those functions and macros. For more information about using the Bluetooth library, see the *Palm OS Programmer's Companion Supplement: Bluetooth*.

## Security Functions

The Bluetooth security functions allow the application to manage a database of devices that have been bonded or paired. To understand this database, it is important to understand the difference between pairing and bonding.

Typically, devices must authenticate with each other every time they connect to each other. This process is called *pairing*. However, the

## Bluetooth Library: General Functions

### Security Functions

---

devices can *bond* instead. Bonding is similar to pairing except that both devices remember the link key for the connection. If the two devices ever want to connect to each other again, they don't need to repeat the pairing process.

Information about paired and bonded devices is stored in a device database on the local device. If a remote device has bonded with the local device, its record remains in the database until it is explicitly deleted. If the remote device has paired with the local device but not bonded with it, the record is removed when the connection to the remote device terminates.

Remote devices that have bonded with the local device are also called *trusted devices*.

**New**

---

### BtLibSecurityFindTrustedDeviceRecord

**Purpose** Search the device database for the device with the specified Bluetooth address. Return the index of the corresponding device record in the database.

**Declared In** BtLib.h

**Prototype** `Err BtLibSecurityFindTrustedDeviceRecord  
(UInt16 btLibRefNum,  
BtLibDeviceAddressTypePtr addrP, UInt16 *index)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `addrP` Bluetooth address of remote device.
- <- `index` Index of the record.

**Result** Returns `btLibErrNoError` if successful. Returns `btLibErrNotFound` if a record with the specified remote device address could not be found.

**See Also** [BtLibSecurityRemoveTrustedDeviceRecord](#),  
[BtLibSecurityGetTrustedDeviceRecordInfo](#)

## **BtLibSecurityGetTrustedDeviceInfo**

**Purpose** Get information from a device record in the device database.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSecurityGetTrustedDeviceInfo
(UInt16 btLibRefNum, UInt16 index,
BtLibDeviceAddressTypePtr addrP,
Char *nameBuffer, UInt8 *nameBufferSize,
BtLibClassOfDeviceType *cod, Boolean *persistent)
```

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `index` Index of the record.
- <- `addrP` Bluetooth address of remote device.
- <- `nameBuffer` Pointer to buffer to store user-friendly name of remote device. You must allocate this buffer. Provide a NULL pointer if the user-friendly name is not needed.
- <-> `nameBufferSize` Size of the `nameBuffer` buffer on entry. On exit, the size of the name.
- <- `cod` Pointer to a [BtLibClassOfDeviceType](#) representing the class of the device. You must allocate this structure. Provide a NULL pointer if the device class is not needed.
- <- `lastConnected` The date since the device last connected. This date is measured in seconds since midnight January 1, 1904. Provide a NULL pointer if the date of last connection is not needed.

## Bluetooth Library: General Functions

### Security Functions

---

`<- persistent` If true, the device is bonded and can connect to the local device without authentication. If false, the device is paired but not bonded—it will need to reauthenticate if it connects again. Provide a NULL pointer if this information is not needed.

**Result** Returns `btLibErrNoError` if successful. Returns `dmErrIndexOutOfRange` if a record with the specified index could not be found.

**See Also** [BtLibSecurityFindTrustedDeviceRecord](#)

**New**

---

## BtLibSecurityNumTrustedDeviceRecords

**Purpose** Return the number of bonded devices in the device database or return the total number of devices in the device database.

**Declared In** `BtLib.h`

**Prototype** `UInt16 BtLibSecurityNumTrustedDeviceRecords (UInt16 btLibRefNum, Boolean persistentOnly)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `persistentOnly`
  - `true` to obtain the total number of bonded devices in the database. These are the same devices that appear in the trusted devices list.
  - `false` to obtain the total number of devices in the device database. This includes the devices that are bonded and the devices that are paired but not bonded.

**Result** Returns the requested number of device records.

**See Also** [BtLibSecurityFindTrustedDeviceRecord](#),  
[BtLibSecurityGetTrustedDeviceRecordInfo](#)

**New** **BtLibSecurityRemoveTrustedDeviceRecord**

**Purpose** Remove a device record from the device database.

**Declared In** BtLib.h

**Prototype** Err BtLibSecurityRemoveTrustedDeviceRecord  
(UInt16 btLibRefNum, UInt16 index)

**Parameters** -> btLibRefNum Reference number for the Bluetooth library.  
-> index Index of the record to remove.

**Result** Returns btLibErrNoError if successful. Returns dmErrIndexOutOfRange if a record with the specified index could not be found.

**See Also** [BtLibSecurityFindTrustedDeviceRecord](#)

## Utility Functions

This section describes functions and macros that are useful when working with the Bluetooth library.

## Bluetooth Library: General Functions

### Utility Functions

---

#### **New** **BtLibAddrAToBtd**

---

**Purpose** Convert an ASCII string a Bluetooth device address in colon-separated form to a 48-bit [BtLibDeviceAddressType](#).

**Declared In** `BtLib.h`

**Prototype** `Err BtLibAddrAToBtd (UInt16 btLibRefNum,  
const Char *addressString,  
BtLibDeviceAddressType *btDevP)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `addressString` String containing ASCII colon-separated Bluetooth device address.
- <- `btDevP` Pointer to a [BtLibDeviceAddressType](#) to store the converted device address.

**Result** Returns `btLibErrNoError` to indicate that the conversion was successful.

**See Also** [BtLibAddrBtdToA](#)

---

## **BtLibAddrBtdToA**

**Purpose** Convert 48-bit [BtLibDeviceAddressType](#) to an ASCII string in colon-separated form.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibAddrBtdToA (UInt16 btLibRefNum,  
BtLibDeviceAddressType *btDevP, Char *spaceP,  
UInt16 spaceSize)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `btDevP` Address of a Bluetooth device. This parameter must not be NULL.
- <- `spaceP` Pointer to a buffer to store the ASCII formatted Bluetooth devices address upon return. This parameter must not be NULL.
- > `spaceSize` Size of the `spaceP` buffer, in bytes. Must be at least 18.

**Result** Returns `btLibErrNoError` if successful. Returns `btLibErrParamErr` if

- `btDevP` is NULL
- `spaceP` is NULL
- `spaceSize` is less than 18, the number of bytes required to store the ASCII formatted address

**See Also** [BtLibAddrAToBtd](#)

## Bluetooth Library: General Functions

### Utility Functions

---

#### **New** **BtLibL2CapHToNL**

---

**Purpose** Macro that converts a 32-bit value from host to L2CAP byte order. L2CAP byte order is little endian.

**Declared In** BtLib.h

**Prototype** BtLibL2CapHToNL (value)

**Parameters** -> value            32-bit value to convert.

**Result** Returns value in L2CAP byte order.

**See Also** [BtLibL2CapHToNS](#), [BtLibL2CapNToHL](#), [BtLibL2CapNToHS](#)

#### **New** **BtLibL2CapHToNS**

---

**Purpose** Macro that converts a 16-bit value from host to L2CAP byte order. L2CAP byte order is little endian.

**Declared In** BtLib.h

**Prototype** BtLibL2CapHToNS (value)

**Parameters** -> value            16-bit value to convert.

**Result** Returns value in L2CAP byte order.

**See Also** [BtLibL2CapHToNL](#), [BtLibL2CapNToHS](#), [BtLibSdpNToHL](#)

  
**New**

---

## **BtLibL2CapNToHL**

**Purpose** Macro that converts a 32-bit value from L2CAP to host byte order. L2CAP byte order is little endian.

**Declared In** BtLib.h

**Prototype** BtLibL2CapNToHL (value)

**Parameters** -> value            32-bit value to convert.

**Result** Returns value in host byte order.

**See Also** [BtLibL2CapNToHS](#), [BtLibL2CapHToNL](#), [BtLibL2CapHToNS](#)

  
**New**

---

## **BtLibL2CapNToHS**

**Purpose** Macro that converts a 16-bit value from L2CAP to host byte order. L2CAP byte order is little endian.

**Declared In** BtLib.h

**Prototype** BtLibL2CapNToHS (value)

**Parameters** -> value            16-bit value to convert.

**Result** Returns value in host byte order.

**See Also** [BtLibL2CapNToHL](#), [BtLibL2CapHToNS](#), [BtLibL2CapHToNL](#)

## Bluetooth Library: General Functions

### Utility Functions

---

#### **New** **BtLibRfCommHToNL**

---

**Purpose** Macro that converts a 32-bit value from host to RFCOMM byte order. RFCOMM byte order is big endian.

**Declared In** `BtLib.h`

**Prototype** `BtLibRfCommHToNL (value)`

**Parameters** `->value`            32-bit value to convertx

**Result** Returns value in RFCOMM byte order.

**See Also** [BtLibRfCommHToNS](#), [BtLibRfCommNToHL](#), [BtLibRfCommNToHS](#)

#### **New** **BtLibRfCommHToNS**

---

**Purpose** Macro that converts a 16-bit value from host to RFCOMM byte order. RFCOMM byte order is big endian.

**Declared In** `BtLib.h`

**Prototype** `BtLibRfCommHToNS (value)`

**Parameters** `->value`            16-bit value to convertx

**Result** Returns value in RFCOMM byte order.

**See Also** [BtLibRfCommHToNL](#), [BtLibRfCommHToNS](#), [BtLibRfCommNToHL](#)

  
**New**

---

## **BtLibRfCommNToHL**

**Purpose** Macro that converts a 32-bit value from RFCOMM to host byte order. RFCOMM byte order is big endian.

**Declared In** `BtLib.h`

**Prototype** `BtLibRfCommNToHL (value)`

**Parameters** `->value` 32-bit value to convertx

**Result** Returns value in host byte order.

**See Also** [BtLibRfCommNToHS](#), [BtLibRfCommHToNL](#), [BtLibRfCommHToNS](#)

  
**New**

---

## **BtLibRfCommNToHS**

**Purpose** Macro that converts a 16-bit value from RFCOMM to host byte order. RFCOMM byte order is big endian.

**Declared In** `BtLib.h`

**Prototype** `BtLibRfCommNToHS (value)`

**Parameters** `->value` 16-bit value to convertx

**Result** Returns value in host byte order.

**See Also** [BtLibRfCommNToHL](#), [BtLibRfCommHToNS](#), [BtLibRfCommHToNL](#)

## Bluetooth Library: General Functions

### Utility Functions

---

#### **New** **BtLibSdpHToNL**

---

**Purpose** Macro that converts a 32-bit value from host to Service Discovery Protocol (SDP) byte order. SDP byte order is big endian.

**Declared In** BtLib.h

**Prototype** BtLibSdpHToNL (value)

**Parameters** ->value            32-bit value to convertx

**Result** Returns value in SDP byte order.

**See Also** [BtLibSdpHToNS](#), [BtLibSdpNToHL](#), [BtLibSdpNToHS](#)

#### **New** **BtLibSdpHToNS**

---

**Purpose** Macro that converts a 16-bit value from host to Service Discovery Protocol (SDP) byte order. SDP byte order is big endian.

**Declared In** BtLib.h

**Prototype** BtLibSdpHToNS (value)

**Parameters** ->value            16-bit value to convertx

**Result** Returns value in SDP byte order.

**See Also** [BtLibSdpHToNL](#), [BtLibSdpNToHS](#), [BtLibSdpNToHL](#)

---

## **BtLibSdpNToHL**

**Purpose** Macro that converts a 32-bit value from Service Discovery Protocol (SDP) to host byte order. SDP byte order is big endian.

**Declared In** BtLib.h

**Prototype** BtLibSdpNToHL (value)

**Parameters** -> value            32-bit value to convertx

**Result** Returns value in host byte order.

**See Also** [BtLibSdpNToHS](#), [BtLibSdpHToNL](#), [BtLibSdpHToNS](#)

---

## **BtLibSdpNToHS**

**Purpose** Macro that converts a 16-bit value from Service Discovery Protocol (SDP) to host byte order. SDP byte order is big endian.

**Declared In** BtLib.h

**Prototype** BtLibSdpNToHS (value)

**Parameters** ->value            16-bit value to convertx

**Result** Returns value in host byte order.

**See Also** [BtLibSdpNToHL](#), [BtLibSdpHToNS](#), [BtLibSdpHToNL](#)

## **Bluetooth Library: General Functions**

### *Utility Functions*

---

# Bluetooth Library: Management

---

The management API of the Bluetooth library supports the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. This chapter presents reference material for the management API:

## [Bluetooth Management Data Structures](#)

This section lists some of the more important types used by the Bluetooth library management functions.

## [Management Callback Events](#)

This section lists the management callback events. Most of the management functions are asynchronous. In other words, they start operations and return before the operations complete. To signal the application that management operations have completed, the Bluetooth library generates *management callback events* by calling a callback function.

## [Management Event Status Codes](#)

When a management event is generated, the `status` field of the associated [BtLibManagementEventType](#) provides information about why the event occurred. This section explains what these codes mean.

## [Library Management Functions](#)

This section describes the functions that open and close the shared library.

## Bluetooth Library: Management

### Bluetooth Management Data Structures

---

#### Management Functions

The management functions handle the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. These functions perform tasks that include discovering devices, working with Asynchronous Connectionless (ACL) links and piconets, and maintaining global settings for the Bluetooth library.

#### Application-Defined Functions

This section describes the callback functions that handle management events.

The header file `BtLib.h` declares the Bluetooth library functions and macros. The header file `BtLibTypes.h` declares the data structures that you use with those functions and macros. For more information about using the Bluetooth library, see the *Palm OS Programmer's Companion Supplement: Bluetooth*.

## Bluetooth Management Data Structures

This section lists some of the more important types used by the Bluetooth library management functions.

**New**

---

### **BtLibAccessibleModeEnum**

The `BtLibAccessibleModeEnum` enum specifies a device's accessibility modes. See the "Generic Access Profile" chapter of the *Specification of the Bluetooth System* for more information about accessibility.

```
typedef enum {
    btLibNotAccessible = 0x00,
    btLibConnectableOnly = 0x02,
    btLibDiscoverableAndConnectable = 0x03
} BtLibAccessibleModeEnum;
```

### Value Descriptions

`btLibConnectableOnly`

The device responds to a page but not an inquiry.

`btLibDiscoverableAndConnectable`

The device responds to both a page and an inquiry.

`btLibNotAccessible`

The device does not respond to a page or an inquiry.

**New**

---

## **BtLibClassOfDeviceType**

The `BtLibClassOfDeviceType` type represents the class of the device and the services it supports.

```
typedef UInt32 BtLibClassOfDeviceType;
```

A device can support multiple services but only belongs to a single class. The class is specified in two parts: the major class, which broadly classifies the type of device, and the minor class, which together with the major class specifies the type of device in more detail.

An example is a simple cellular telephone. It provides Telephony services. Its major device class is `Phone`, and its minor device class is `Cellular`.

The *Bluetooth Assigned Numbers* specification defines a device class as having three bit fields. One field specifies the major service classes supported by the device. Another field specifies the major device class. The third field specifies the minor device class.

The constants provided here allow you to construct a device class that conforms to the Bluetooth specification. You simply perform a logical OR of the constants representing the service classes the device supports, the constant representing the device's major class, and the constant representing the device's minor class.

For example, device class of the simple cellular telephone can be computed as follows:

## Bluetooth Library: Management

### Bluetooth Management Data Structures

---

```
cellPhoneCOD = btLibCOD_Telephony |  
               btLibCOD_Major_Phone |  
               BtLibCOD_Minor_Phone_Cellular;
```

Constants are also provided to mask the individual bit fields in a device class.

### Major Service Classes

These constants define the Bluetooth major service classes. The service classes are described in the *Specification of the Bluetooth System*.

```
btLibCOD_LimitedDiscoverableMode  
btLibCOD_Networking  
btLibCOD_Rendering  
btLibCOD_Capturing  
btLibCOD_ObjectTransfer  
btLibCOD_Audio  
btLibCOD_Telephony  
btLibCOD_Information
```

### Major Device Classes

These constants define the Bluetooth major device classes. The major device classes are described in the *Specification of the Bluetooth System*.

```
btLibCOD_Major_Misc  
btLibCOD_Major_Computer  
btLibCOD_Major_Phone  
btLibCOD_Major_Lan_Access_Point  
btLibCOD_Major_Audio  
btLibCOD_Major_Peripheral  
btLibCOD_Major_Unclassified
```

### Computer Minor Device Classes

These constants define the minor device classes associated with the computer major class. They are described in the *Bluetooth Assigned Numbers* specification.

```
btLibCOD_Minor_Comp_Unclassified  
btLibCOD_Minor_Comp_Desktop  
btLibCOD_Minor_Comp_Server
```

```
btLibCOD_Minor_Comp_Laptop  
btLibCOD_Minor_Comp_Handheld  
btLibCOD_Minor_Comp_Palm
```

### **Phone Minor Device Classes**

These constants define the minor device classes are associated with the computer major class. They are described in the *Bluetooth Assigned Numbers* specification.

```
btLibCOD_Minor_Phone_Unclassified  
btLibCOD_Minor_Phone_Cellular  
btLibCOD_Minor_Phone_Cordless  
btLibCOD_Minor_Phone_Smart  
btLibCOD_Minor_Phone_Modem
```

### **LAN Access Point Minor Device Classes**

These constants define load factors for the LAN access point major device class. LAN access point load factors are described in more detail in the *Bluetooth Assigned Numbers* specification.

```
btLibCOD_Minor_Lan_0  
Fully available  
  
btLibCOD_Minor_Lan_17  
1-17% utilized  
  
btLibCOD_Minor_Lan_33  
17-33% utilized  
  
btLibCOD_Minor_Lan_50  
33-50% utilized  
  
btLibCOD_Minor_Lan_67  
50-67% utilized  
  
btLibCOD_Minor_Lan_83  
67-83% utilized  
  
btLibCOD_Minor_Lan_99  
83-99% utilized  
  
btLibCOD_Minor_Lan_NoService  
Fully utilized
```

## Bluetooth Library: Management

### Bluetooth Management Data Structures

---

#### Audio Minor Device Classes

These constants define the minor classes associated with the audio major class. They are described in more detail in the *Bluetooth Assigned Numbers* specification.

```
btLibCOD_Minor_Audio_Unclassified  
btLibCOD_Minor_Audio_Headset
```

#### Masks

These constants define bit masks to isolate certain fields of the device class.

```
btLibCOD_Service_Mask  
    A mask to isolate the major service class field  
    from the other fields of the device class.
```

```
btLibCOD_Major_Mask  
    A mask to isolate the major device class field  
    from the other fields of the device class.
```

```
btLibCOD_Minor_Mask  
    A mask to isolate the minor device class field  
    from the other fields of the device class.
```

```
btLibCOD_ServiceAny  
    Used as a device filter for the  
    BtLibDiscoverMultipleDevices and  
    BtLibDiscoverSingleDevice functions.  
    With this filter, devices providing any service  
    appear in the device list. Same as  
    btLibCOD_Service_Mask.
```

```
btLibCOD_Major_Any  
    Used as a device filter for the  
    BtLibDiscoverMultipleDevices and  
    BtLibDiscoverSingleDevice functions.  
    With this filter, devices in any major device  
    class appear in the device list. Same as  
    btLibCOD_Major_Mask.
```

`btLibCOD_Minor_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices](#) and [BtLibDiscoverSingleDevice](#) functions. With this filter, devices in any minor device class appear in the device list. Same as `btLibCOD_Minor_Mask`.

`btLibCOD_Minor_Comp_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices](#) and [BtLibDiscoverSingleDevice](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Computer`, all devices broadcasting themselves as computers appear in the device list. Same as `btLibCOD_Minor_Any`.

`btLibCOD_Minor_Phone_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices](#) and [BtLibDiscoverSingleDevice](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Phone`, all devices broadcasting themselves as phones appear in the device list. Same as `btLibCOD_Minor_Any`.

`btLibCOD_Minor_LAN_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices](#) and [BtLibDiscoverSingleDevice](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Lan_Access_Point`, all devices broadcasting themselves as LAN access points appear in the device list. Same as `btLibCOD_Minor_Any`.

## Bluetooth Library: Management

### Bluetooth Management Data Structures

---

`btLibCOD_Minor_Audio_Any`

Used as a device filter for the [BtLibDiscoverMultipleDevices](#) and [BtLibDiscoverSingleDevice](#) functions. When this filter is used in conjunction with `btLibCOD_Major_Audio`, all devices broadcasting themselves as audio devices appear in the device list. Same as `btLibCOD_Minor_Any`.

**New**

---

## BtLibConnectionRoleEnum

The `BtLibConnectionRoleEnum` enum specifies all the connection roles a device can have. A device can either be a master or a slave.

```
typedef enum {
    btLibMasterRole,
    btLibSlaveRole
} BtLibConnectionRoleEnum;
```

### Value Descriptions

`btLibMasterRole`

The device is a master.

`btLibSlaveRole` The device is a slave.

**New**

---

## BtLibDeviceAddressType

The `BtLibDeviceAddressType` structure represents a 48-bit Bluetooth device address.

```
#define btLibDeviceAddressSize 6

typedef struct BtLibDeviceAddressType {
    UInt8 address[btLibDeviceAddressSize];
} BtLibDeviceAddressType;
```

---

## BtLibFriendlyNameType

The `BtLibFriendlyNameType` structure contains the user-friendly name of a device.

```
typedef struct BtLibFriendlyNameType {
    UInt8  *name;
    UInt8  nameLength;
} BtLibFriendlyNameType,
*BtLibFriendlyNameTypePtr;
```

### Field Descriptions

|                         |                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>name</code>       | Array of characters, encoded according to the UTF-8 standard, containing the user-friendly name of the device. This array is not null-terminated. |
| <code>nameLength</code> | The number of characters in the user-friendly name. The maximum size is 249 characters.                                                           |

---

## BtLibManagementEventType

The `BtLibManagementEventType` structure contains detailed information regarding a management callback event. All management events have some common data. Most management events have data specific to those events. The specific data uses a union that is part of the `BtLibManagementEvent` data structure.

```
typedef struct _BtLibManagementEventType {
    BtLibManagementEventEnum event;
    Err status;
    union {
        ...
    } eventData;
} BtLibManagementEventType;
```

## Bluetooth Library: Management

### Management Callback Events

---

#### Field Descriptions

|           |                                                                                                                                                                   |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| event     | A <code>BtLibManagementEventEnum</code> enum member that indicates which management event has occurred. See <a href="#">Management Callback Events</a> .          |
| status    | Status of the event. The <a href="#">Management Callback Events</a> section gives more details about how to interpret this field for specific events.             |
| eventData | Data associated with the event. The member of this union that is valid depends on the event. See <a href="#">Management Callback Events</a> for more information. |

A `BtLibManagementEventType` object is passed as the first argument of the [BtLibManagementCallback](#) callback function.

## Management Callback Events

The management functions of the Bluetooth library support the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. Most of the management functions are asynchronous. In other words, they start operations and return before the operations complete. To signal the application that management operations have completed, the Bluetooth library generates *management callback events* by calling a callback function.

You specify the callback function using the [BtLibRegisterManagementNotification](#) function. When an event occurs, the callback function is called with two parameters: a pointer to a [BtLibManagementEventType](#) structure and a pointer to a user-defined structure.

The `BtLibManagementEventType` structure contains an event field, which indicates the reason the callback is called, a status field, which contains status information associated with the event, and a union of several structures. The member of the union that is valid depends on the event. The meaning of the events is described in the following sections.

For more information about the status field, see [Management Event Status Codes](#).

## **btLibManagementEventAccessibilityChange**

The accessibility mode of the local device has changed.

For this event, the eventData field contains the following field:

```
BtLibAccessibleModeEnum accessible;
```

This [BtLibAccessibleModeEnum](#) represents the new accessibility mode of the local device.

This event can result from calling [BtLibOpen](#), [BtLibPiconetCreate](#), or [BtLibSetGeneralPreference](#).

## **btLibManagementEventAclConnectInbound**

A remote device has established an ACL link to the local device.

For this event, the eventData field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

## **btLibManagementEventAclConnectOutbound**

An ACL link has been established with a remote device.

If the status field contains `btLibErrNoError`, the ACL link is connected, and the remote device address can be found in the eventData field. Otherwise the connection failed and the status field indicates the reason for the failure. See [Management Event Status Codes](#) for more information.

For this event, the eventData field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

This event can result from calling [BtLibLinkConnect](#).

#### **btLibManagementEventAclDisconnect**

An ACL link has been disconnected. The `status` field indicates the reason the link was disconnected. See [Management Event Status Codes](#).

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contain the address of the disconnected device.

This event can result from calling [BtLibLinkDisconnect](#) or [BtLibPiconetDestroy](#).

#### **btLibManagementEventAuthentication Complete**

The authentication of a remote device has completed.

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

If the authentication is successful, the `status` field contains `btLibErrNoError`. If the user cancels the passkey request, the `status` field contains `btLibErrCanceled`. Otherwise, the `status` field indicates the reason the authentication failed. See [Management Event Status Codes](#).

This event can result from calling [BtLibLinkSetState](#).

#### **btLibManagementEventEncryptionChange**

Encryption for a link has been enabled or disabled.

For this event, the `eventData` field contains the following structure:

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    Boolean enabled;  
} encryptionChange;
```

### Field Descriptions

|         |                                                                                       |
|---------|---------------------------------------------------------------------------------------|
| bdAddr  | A <a href="#">BtLibDeviceAddressType</a> containing the address of the remote device. |
| enabled | true when encryption for the link has been enabled; false otherwise.                  |

This event can result from calling [BtLibLinkSetState](#).

### **btLibManagementEventInquiryCanceled**

The device inquiry has been canceled because the application called [BtLibCancelInquiry](#).

### **btLibManagementEventInquiryComplete**

The device inquiry started with the [BtLibStartInquiry](#) function has completed.

### **btLibManagementEventInquiryResult**

A remote device has responded to an inquiry that was started with the [BtLibStartInquiry](#) function.

For this event, the eventData field contains the following structure:

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibClassOfDeviceType classOfDevice;  
} inquiryResult;
```

### Field Descriptions

|               |                                                                                       |
|---------------|---------------------------------------------------------------------------------------|
| bdAddr        | A <a href="#">BtLibDeviceAddressType</a> containing the address of the remote device. |
| classOfDevice | A <a href="#">BtLibClassOfDeviceType</a> representing the class of the remote device. |

### **btLibManagementEventLocalNameChange**

The user-friendly name of the local device has changed.

## Bluetooth Library: Management

### Management Callback Events

---

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibDeviceAddressType bdAddr;
    BtLibFriendlyNameType name;
} nameResult;
```

#### Field Descriptions

`bdAddr` A [BtLibDeviceAddressType](#) containing the address of the local device.

`name` A [BtLibFriendlyNameType](#) containing the new name.

This event can result from calling [BtLibOpen](#).

## btLibManagementEventModeChange

A slave has changed its mode. A slave can be in active, sniff, hold, or park mode.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibDeviceAddressType bdAddr;
    BtLibLinkModeEnum curMode;
    UInt16 interval;
} modeChange;
```

#### Field Descriptions

`bdAddr` A [BtLibDeviceAddressType](#) containing the address of the remote device.

`curMode` A [BtLibLinkModeEnum](#) indicating the new mode of remote device

`interval` The time in units of 0.625 ms the remote device will stay in the new mode, if applicable. The time period is a standard time period in the Bluetooth specification.

### **BtLibLinkModeEnum**

The `BtLibLinkModeEnum` enum specifies the modes a slave can have. According to the *Specification of the Bluetooth System*, a slave can be in active, sniff, hold, or park mode. However, the Bluetooth library only supports the hold and active modes.

```
typedef enum {
    btLibSniffMode,
    btLibHoldMode,
    btLibParkMode,
    btLibActiveMode
} BtLibLinkModeEnum;
```

### **Value Descriptions**

|                              |                                                                   |
|------------------------------|-------------------------------------------------------------------|
| <code>btLibActiveMode</code> | The slave is active.                                              |
| <code>btLibHoldMode</code>   | The slave is in hold mode.                                        |
| <code>btLibParkMode</code>   | The slave is in park mode. This mode is not currently supported.  |
| <code>btLibSniffMode</code>  | The slave is in sniff mode. This mode is not currently supported. |

### **btLibManagementEventNameResult**

A remote device name request has completed. If the `status` field is `btLibErrNoError`, the name is available. Otherwise, the name request failed, and the `status` field indicates the reason for the failure. See [Management Event Status Codes](#).

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibDeviceAddressType bdAddr;
    BtLibFriendlyNameType name;
} nameResult;
```

### **Field Descriptions**

|                     |                                                                                       |
|---------------------|---------------------------------------------------------------------------------------|
| <code>bdAddr</code> | A <a href="#">BtLibDeviceAddressType</a> containing the address of the remote device. |
|---------------------|---------------------------------------------------------------------------------------|

## Bluetooth Library: Management

### Management Callback Events

---

name                    A [BtLibFriendlyNameType](#) containing the name of the remote device.

The [BtLibGetRemoteDeviceName](#) function is used to start a remote device name request.

### **btLibManagementEventPasskeyRequest**

A remote device has requested a passkey. Your application does not have to respond to this request—the Bluetooth library automatically handles it.

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType bdAddr;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device.

Because a passkey can be requested during or after a link is established, consider disabling any failure timers while the passkey dialog is up. The [btLibManagementEventPasskeyRequestComplete](#) event signals the completion of the passkey entry.

### **btLibManagementEventPasskeyRequestComplete**

A passkey request has been processed. The status code for this event is set to `btLibErrNoError` if the passkey was entered or `btLibErrCanceled` if passkey entry was cancelled. Note that this event does **not** tell you that the authentication completed.

### **btLibManagementEventPiconetCreated**

The piconet has been created. This event can result from calling [BtLibPiconetCreate](#).

### **btLibManagementEventPiconetDestroyed**

The piconet has been destroyed. This event can result from calling [BtLibPiconetDestroy](#).

## **btLibManagementEventRadioState**

This event is generated when the Bluetooth radio changes state. The radio changes state when the radio is disconnected, the power is turned on or off, the radio resets, or the radio fails to initialize. The status code for this event explains why the event gets generated.

### **Status Codes**

`btLibErrRadioInitialized`

The Bluetooth radio has initialized successfully. You can now call management functions.

`btLibErrRadioInitFailed`

The Bluetooth radio failed to initialize. The application can assume all pending Bluetooth operations have failed. However, some pending operations will still generate events and modify memory supplied by the application.

To try to initialize the radio again, you need to close the library and reopen it.

## Bluetooth Library: Management

### *Management Callback Events*

---

#### `btLibErrRadioFatal`

A fatal radio error occurred. This usually signifies that the host has lost contact with the radio, for example, when the user disconnects the radio, or the device turns off. The application can assume that all pending operations have failed. However, some pending operations will still generate events and modify memory supplied by the application.

When a fatal radio error occurs, the Bluetooth stack resets the radio and tries once to reinitialize it, which generates another `btLibManagementEventRadioState` event with a status code of `btLibErrRadioInitialized`, or `btLibErrRadioInitFailed` depending on whether or not the initialization succeeded.

#### `btLibErrRadioSleepWake`

The radio was reset because the device went to sleep. The application can assume all pending operations have failed. However, some pending operations will still generate events and modify memory supplied by the application.

The Bluetooth stack resets the radio and tries once to reinitialize it, which generates another `btLibManagementEventRadioState` event with a status code of `btLibErrRadioInitialized`, or `btLibErrRadioInitFailed` depending on whether or not the initialization succeeded.

This event can result from calling [BtLibOpen](#).

### **btLibManagementEventRoleChange**

The master and slave devices for a link have switched roles.

For this event, the `eventData` field contains the following structure:

```
struct {  
    BtLibDeviceAddressType bdAddr;  
    BtLibConnectionRoleEnum newRole;  
} roleChange;
```

**Field Descriptions**

|                      |                                                                                          |
|----------------------|------------------------------------------------------------------------------------------|
| <code>bdAddr</code>  | A <a href="#">BtLibDeviceAddressType</a> containing the address of the remote device.    |
| <code>newRole</code> | A <a href="#">BtLibConnectionRoleEnum</a> representing the new role of the local device. |

## Management Event Status Codes

When a management event is generated, the `status` field of the associated [BtLibManagementEventType](#) provides information about why the event occurred. The following status codes can occur with a management event.

|                                               |                                |
|-----------------------------------------------|--------------------------------|
| <code>btLibErrNoError</code>                  | Success.                       |
| <code>btLibMeStatusAuthenticateFailure</code> | Authentication failure         |
| <code>btLibMeStatusCommandDisallowed</code>   | Command disallowed             |
| <code>btLibMeStatusConnectionTimeout</code>   | Connection timeout             |
| <code>btLibMeStatusHardwareFailure</code>     | Hardware Failure               |
| <code>btLibMeStatusHostTimeout</code>         | Host timeout                   |
| <code>btLibMeStatusInvalidHciParam</code>     | Invalid HCI command parameters |
| <code>btLibMeStatusInvalidLmpParam</code>     | Invalid LMP Parameters         |

## Bluetooth Library: Management

### Management Event Status Codes

---

|                                              |                                           |
|----------------------------------------------|-------------------------------------------|
| <code>btLibMeStatusLimitedResources</code>   | Host rejected due to limited resources    |
| <code>btLibMeStatusLmpResponseTimeout</code> |                                           |
| <code>btLibMeStatusLmpTransdCollision</code> |                                           |
| <code>btLibMeStatusLmpPduNotAllowed</code>   |                                           |
| <code>btLibMeStatusLocalTerminated</code>    | Terminated by local host                  |
| <code>btLibMeStatusLowResources</code>       | Other end terminated due to low resources |
| <code>btLibMeStatusMaxAclConnections</code>  | Max number of ACL connections to a device |
| <code>btLibMeStatusMaxConnections</code>     | Max number of connections                 |
| <code>btLibMeStatusMaxScoConnections</code>  | Max number of SCO connections to a device |
| <code>btLibMeStatusMemoryFull</code>         | Memory full                               |
| <code>btLibMeStatusMissingKey</code>         | Missing key                               |
| <code>btLibMeStatusNoConnection</code>       | No connection                             |
| <code>btLibMeStatusPageTimeout</code>        | Page timeout                              |
| <code>btLibMeStatusPairingNotAllowed</code>  | Pairing not allowed                       |
| <code>btLibMeStatusPersonalDevice</code>     | Host rejected (remote is personal device) |
| <code>btLibMeStatusPowerOff</code>           | Other end terminated (about to power off) |

|                                                |                                        |
|------------------------------------------------|----------------------------------------|
| <code>btLibMeStatusRepeatedAttempts</code>     | Repeated attempts                      |
| <code>btLibMeStatusRoleChangeNotAllowed</code> | Change not allowed                     |
| <code>btLibMeStatusScoAirModeRejected</code>   | SCO Air Mode Rejected                  |
| <code>btLibMeStatusScoIntervalRejected</code>  | SCO Interval Rejected                  |
| <code>btLibMeStatusScoOffsetRejected</code>    | SCO Offset Rejected                    |
| <code>btLibMeStatusSecurityError</code>        | Host rejected due to security reasons  |
| <code>btLibMeStatusUnknownHciCommand</code>    | Unknown HCI Command                    |
| <code>btLibMeStatusUnknownLmpPDU</code>        | Unknown LMP PDU                        |
| <code>btLibMeStatusUnspecifiedError</code>     | Unspecified Error                      |
| <code>btLibMeStatusUnsupportedFeature</code>   | Unsupported feature or parameter value |
| <code>btLibMeStatusUnsupportedLmpParam</code>  | Unsupported LMP Parameter Value        |
| <code>btLibMeStatusUnsupportedRemote</code>    | Unsupported Remote Feature             |
| <code>btLibMeStatusUserTerminated</code>       | Other end terminated (user)            |

## Library Management Functions

This section describes the general Bluetooth library management functions.

## Bluetooth Library: Management

### Library Management Functions

---

#### **New** BtLibClose

---

**Purpose** Close the Bluetooth library.

**Declared In** BtLib.h

**Prototype** Err BtLibClose (UInt16 btLibRefNum)

**Parameters** -> btLibRefNum Reference number for the Bluetooth library.

**Result** Returns btLibErrNoError if the library successfully closes.  
Returns btLibErrNotOpen if the referenced Bluetooth library was not open.

**Comments** Applications must call this function when they no longer need the Bluetooth library. If the Bluetooth library open count is one, this function closes existing connections, saves the current accessibility mode, sets the accessible mode according to the preferences panel, and shuts down the library. If the Bluetooth library open count is greater than one, this function decrements the open count.

**See Also** [BtLibOpen](#)

#### **New** BtLibOpen

---

**Purpose** Open and initialize the Bluetooth library.

**Declared In** BtLib.h

**Prototype** Err BtLibOpen (UInt16 btLibRefNum,  
Boolean allowStackToFail)

**Parameters** -> btLibRefNum Reference number for the Bluetooth library.

-> `allowStackToFail`

If true, opens the library even if the stack or radio fails to initialize. Otherwise, does not open the library if the stack or radio fails to initialize.

**Result** Returns one of the following values:

`btLibErrNoError`

Success.

`btLibErrAlreadyOpen`

This status code is not really an error. It is returned if the library was already open. In this case, the open count is incremented.

`btLibErrInUseByService`

The library is currently in use by a Bluetooth service.

`btLibErrOutOfMemory`

Not enough memory available to open the library.

`btLibErrRadioInitFailed`

The Bluetooth stack or radio could not be initialized. If `allowStackToFail` is true, the library still opens after this error occurs.

Applications must call this function before using the Bluetooth library. If the Bluetooth library is not already open, `BtLibOpen` opens the library, initializes it, and starts up the protocol stack component of the library. Otherwise it increments its open count.

The `allowStackToFail` parameter allows the library to be opened even if the Bluetooth stack or radio fails to initialize. It is useful for applications that only want to use the Bluetooth library's utility functions but not the radio. However, any application that needs to communicate with the radio must set `allowStackToFail` to false.

This function generates three events: a

[`btLibManagementEventRadioState`](#) event with a status of `btLibErrRadioInitialized`, a

[`btLibManagementEventLocalNameChange`](#) event indicating the

## Bluetooth Library: Management

### Management Functions

---

local name of the device, and a [btLibManagementEventAccessibilityChange](#) event indicating the accessibility of the device.

**See Also** [BtLibClose](#)

## Management Functions

The management functions handle the lower levels of the Bluetooth specification, specifically the radio, baseband, and Link Manager Protocol specifications. These functions perform tasks that include discovering devices, working with Asynchronous Connectionless (ACL) links and piconets, and maintaining global settings for the Bluetooth library.

---

### **New** BtLibCancelInquiry

**Purpose** Cancel a Bluetooth inquiry in process.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibCancelInquiry (UInt16 btLibRefNum)`

**Parameters** `-> btLibRefNum` Reference number for the Bluetooth library.

**Result** Returns one of the following values:

`btLibErrNoError`

The inquiry process was canceled before it started.

`btLibErrPending`

The cancellation is pending. When it succeeds, notification will be provided through a management callback event.

`btLibErrInProgress`

The inquiry is already being canceled.

`btLibErrNotInProgress`

No inquiry is in progress to be canceled.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** The function cancels inquiries initiated by [BtLibStartInquiry](#). The [btLibManagementEventInquiryCanceled](#) callback event indicates that the cancellation has completed.

A Bluetooth discovery initiated using either [BtLibDiscoverSingleDevice](#) or [BtLibDiscoverMultipleDevices](#) cannot be canceled with this function. Only the user can cancel these inquiries by tapping the Cancel button.

**See Also** [BtLibStartInquiry](#)

**New**

---

## **BtLibDiscoverMultipleDevices**

**Purpose** Discover all available devices, present them in the user interface, and allow the user to select one or more of these devices.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibDiscoverMultipleDevices
(UInt16 btLibRefNum, Char *instructionTxt,
Char *buttonTxt,
BtLibClassOfDeviceType *deviceFilterList,
UInt8 deviceFilterListLen,
UInt8 *numDevicesSelected, Boolean addressAsName,
Boolean showLastList)
```

**Parameters** -> `btLibRefNum` Reference number for the Bluetooth library.

## Bluetooth Library: Management

### Management Functions

---

- > `instructionTxt`  
Text displayed at the top of the selection box. Pass NULL to display the default text. The default text is "Select one or more devices:"
- > `buttonTxt` Text for the OK button. Pass NULL to display the default text. The default button text is "OK"
- > `deviceFilterList`  
Array of [BtLibClassOfDeviceTypes](#). This function presents to the user only the remote devices whose class matches a class in this list. If `deviceFilterList` is NULL, this function presents to the user all discovered devices.
- > `deviceFilterListLen`  
Number of elements in `deviceFilterList`.
- <- `numDevicesSelected`  
Number of selected devices. To obtain the actual device list, use the `BtLibGetSelectedDevices` function.
- > `addressAsName`  
If true, display the Bluetooth addresses of the remote devices instead of their names. This option is available for debugging purposes.
- > `showLastList`  
If true, causes all other parameters to be ignored and displays the same list as the previous call to `BtLibDiscoverMultipleDevices`.

**Result** Returns one of the following values:

- `btLibErrNoError`  
Success
- `btLibErrCanceled`  
User canceled discovery.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This blocking call performs a full discovery for an application, including name and feature retrieval and testing. This function takes over the UI and presents a choice box to the user, allowing the user to select multiple devices from the list of devices that were discovered. This function does not return until the user chooses one or more devices, or cancels.

Setting the `showLastList` parameter to `true` allows you to present to the user the list of devices displayed in the previous call to `BtLibDiscoverMultipleDevices` or [BtLibDiscoverSingleDevice](#). This feature can be useful because a full discovery process takes approximately ten seconds. The cached device list remains valid even after you close the library, allowing other Bluetooth applications to use it.

Note that [BtLibStartInquiry](#) overwrites the cached device list. If you are using the `showLastList` feature, you should avoid calling `BtLibStartInquiry` between calls to `BtLibDiscoverMultipleDevices` or `BtLibDiscoverSingleDevice`.

Use [BtLibGetSelectedDevices](#) to retrieve the list of devices that the user selected.

**See Also** [BtLibGetSelectedDevices](#), [BtLibDiscoverSingleDevice](#)

## **New** BtLibDiscoverSingleDevice

**Purpose** Discover all available devices, present them in the user interface, and allow the user to select one of these devices.

**Declared In** BtLib.h

**Prototype**

```
Err BtLibDiscoverSingleDevice
(UInt16 btLibRefNum, Char *instructionTxt,
BtLibClassOfDeviceType *deviceFilterList,
UInt8 deviceFilterListLen,
BtLibDeviceAddressType *selectedDeviceP,
Boolean addressAsName, Boolean showLastList)
```

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > instructionTxt  
Text displayed at the top of the selection box. Pass NULL to display the default text. The default text is "Select a device:"
- > deviceFilterList  
Array of [BtLibClassOfDeviceTypes](#). This function displays only the remote devices whose class matches a class in this list. If deviceFilterList is NULL, this function displays all discovered devices.
- > deviceFilterListLen  
Number of elements in deviceFilterList.
- <- selectedDeviceP  
Pointer to a [BtLibDeviceAddressType](#) where this function stores the address of the device the user selects. You need to allocate this space before calling this function.
- > addressAsName  
If true, display the Bluetooth addresses of the remote devices instead of their names. This option is available for debugging purposes.

-> `showLastList`

If `true`, causes all other parameters to be ignored and displays the same list as the previous call to `BtLibDiscoverSingleDevice`.

**Result** Returns one of the following values:

`btLibErrNoError`

Success

`btLibErrCanceled`

User canceled the discovery.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This blocking call performs a full discovery for an application, including name and feature retrieval and testing. This function takes over the UI and presents a choice box to the user, allowing the user to select a device from the list of devices that were discovered. This function does not return until the user chooses a device or cancels.

Setting the `showLastList` parameter to `true` allows you to present to the user the list of devices displayed in the previous call to `BtLibDiscoverSingleDevice` or [BtLibDiscoverMultipleDevices](#). This feature can be useful because a full discovery process takes approximately ten seconds. The cached device list remains valid even after you close the library, allowing other Bluetooth applications to use it.

Note that [BtLibStartInquiry](#) overwrites the cached device list. If you are using the `showLastList` feature, you should avoid calling `BtLibStartInquiry` between calls to `BtLibDiscoverSingleDevice` or `BtLibDiscoverMultipleDevices`.

**See Also** [BtLibDiscoverMultipleDevices](#)

## **New** BtLibGetGeneralPreference

---

**Purpose** Get one of the general management preferences.

**Declared In** BtLib.h

**Prototype** `Err BtLibGetGeneralPreference  
(UInt16 btLibRefNum, BtLibGeneralPrefEnum pref,  
void *prefValue, UInt16 prefValueSize)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `pref` General preference to get.
- <- `prefValue` Pointer to a buffer to hold the value of the preference. You must allocate this buffer. This parameter must not be NULL.
- > `prefValueSize` Size, in bytes, of the `prefValue` buffer. You must set this size so it matches the size of the retrieved preference.

**Result** Returns one of the following values:

`btLibErrNoError`

Success.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrParamError`

One or more parameters is invalid. Be sure that the `prefValueSize` parameter matches the size of the preference value.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** Specify the preference with a member of the `BtLibGeneralPreferenceEnum`.

### **BtLibGeneralPreferenceEnum**

The `BtLibGeneralPreferenceEnum` enum specifies the general preferences that can be accessed using the [BtLibSetGeneralPreference](#) and [BtLibGetGeneralPreference](#) functions.

```
typedef enum {
    btLibPref_Name,
    btLibPref_UnconnectedAccessible,
    btLibPref_CurrentAccessible,
    btLibPref_LocalClassOfDevice,
    btLibPref_LocalDeviceAddress
} BtLibGeneralPrefEnum;
```

### **Value Descriptions**

`btLibPref_CurrentAccessible`

This preference is a [BtLibAccessibleModeEnum](#) indicating the current accessibility mode of the local device.

`btLibPref_LocalClassOfDevice`

This preference is a [BtLibClassOfDeviceType](#) indicating the class of the local device. You should never set this preference.

`btLibPref_Name`

This preference is a [BtLibFriendlyNameType](#) containing the user-friendly name of the local device. If you retrieve this preference, you also need to allocate a buffer and set the `BtLibFriendlyNameType`'s `name` and `nameLength` fields to the buffer pointer and buffer length, respectively.

You should never set this preference.

## Bluetooth Library: Management

### Management Functions

---

`btLibPref_UnconnectedAccessible`

This preference is a [BtLibAccessibleModeEnum](#) indicating the accessibility mode of the local device when it is unconnected. You should never set this preference.

**See Also** [BtLibSetGeneralPreference](#)

---

### **New** **BtLibGetRemoteDeviceName**

**Purpose** Get the name of the remote device with the specified address.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibGetRemoteDeviceName (UInt16 btLibRefNum,  
BtLibDeviceAddressTypePtr remoteDeviceP,  
BtLibFriendlyNameType *nameP,  
BtLibGetNameEnum retrievalMethod)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `remoteDeviceP`  
Pointer to a [BtLibDeviceAddressType](#) containing the address of the device whose name is desired.
- <-> `nameP`  
Pointer to a [BtLibFriendlyNameType](#) structure in which to store the results of the lookup. You must allocate this structure and the name buffer it points to. You also must specify the size of the buffer in the `nameLength` field of the structure. When the function returns, the `nameLength` field contains the actual length of the name. This parameter must not be NULL.

-> retrievalMethod

Method used to retrieve the user-friendly remote device name. See [BtLibGetNameEnum](#).

**Result** Returns one of the following values:

btLibErrNoError

The name structure was successfully retrieved from the cache. No notification event will be generated.

btLibErrBusy There is already a name request pending.

btLibErrNotOpen

The referenced Bluetooth library is not open.

btLibErrPending

The results will be returned through a notification.

btLibErrStackNotOpen

The Bluetooth stack failed to initialize when the library was opened.

**Comments** The Bluetooth library maintains a cache of 50 device names. If the retrievalMethod parameter is btLibCachedThenRemote, this function first checks the cache for a name. If the name is in the cache, the value is returned immediately in the nameP parameter. If the name is not in the cache, the function queries the remote device for its name, forming a temporary ACL connection if one is not already in place. In this case, the function returns btLibErrPending and generates a [btLibManagementEventNameResult](#) event when the name is available.

Other values of the retrievalMethod parameter can instruct this function to look for the name only in the cache or only on the remote device. See [BtLibGetNameEnum](#) for more information.

### **BtLibGetNameEnum**

The BtLibGetNameEnum enum specifies whether to retrieve a device name from the cache, the remote device, or both.

## Bluetooth Library: Management

### Management Functions

---

```
typedef enum {  
    btLibCachedThenRemote,  
    btLibCachedOnly,  
    btLibRemoteOnly  
} BtLibGetNameEnum;
```

#### **Value Descriptions**

btLibCachedOnly

Look for a name in the cache. If the name is not in the cache, fail.

btLibCachedThenRemote

Look for a name in the cache. If the name is not in the cache, ask the remote device.

btLibRemoteOnly

Ignore any cached names and ask the remote device for its name.

**New**

---

### **BtLibGetSelectedDevices**

#### **Purpose**

Get the list of devices selected during the last call to [BtLibDiscoverMultipleDevices](#).

#### **Declared In**

BtLib.h

#### **Prototype**

```
Err BtLibGetSelectedDevices (UInt16 btLibRefNum,  
    BtLibDeviceAddressType *selectedDeviceArray,  
    UInt8 arraySize, UInt8 *numDevicesReturned)
```

#### **Parameters**

-> btLibRefNum Reference number for the Bluetooth library.

<->selectedDeviceArray  
Array into which the results of the [BtLibDiscoverMultipleDevices](#) function should be placed. You must allocate this array of [BtLibDeviceAddressTypes](#).

-> arraySize Number of elements in the selectedDeviceArray you allocated.

```
<- numDevicesReturned
    Number of results placed in
    selectedDeviceArray.
```

**Result** Returns `btLibErrNoError` if the query is successful. Returns `btLibErrNotOpen` if the referenced Bluetooth library is not open or `btLibErrStackNotOpen` if the Bluetooth stack failed to initialize when the library was opened.

**Comments** No callback events.

**See Also** [BtLibDiscoverMultipleDevices](#)

---

## **New** **BtLibLinkConnect**

**Purpose** Create a Bluetooth Asynchronous Connectionless (ACL) link.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibLinkConnect (UInt16 btLibRefNum, BtLibDeviceAddressTypePtr remoteDeviceP)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `remoteDeviceP` Pointer to the a [BtLibDeviceAddressType](#) containing the address of the remote device.

**Result** Returns one of the following values:

- `btLibErrPending`  
The results will be returned through a callback event.
- `btLibErrAlreadyConnected`  
The device is already in a pre-existing connection and cannot create a new connection.

## Bluetooth Library: Management

### Management Functions

---

|                                   |                                                                                                             |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>btLibErrBluetoothOff</code> | The Bluetooth radio is off. The user can turn the radio on and off with a setting in the preferences panel. |
| <code>btLibErrBusy</code>         | A piconet is currently being created or destroyed.                                                          |
| <code>btLibErrNotOpen</code>      | The referenced Bluetooth library is not open.                                                               |
| <code>btLibErrStackNotOpen</code> | The Bluetooth stack failed to initialize when the library was opened.                                       |
| <code>btLibErrTooMany</code>      | Cannot create another ACL link because the maximum allowed number has already been reached.                 |

**Comments** An ACL link is a packet-switched physical level connection between two devices that is needed before the devices can form a RFCOMM or L2CAP connection.

When the connection is established or if it fails to be established, the [btLibManagementEventAclConnectOutbound](#) event is generated.

**See Also** [BtLibLinkDisconnect](#)

---

### **New** BtLibLinkDisconnect

**Purpose** Disconnect an existing ACL Link.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibLinkDisconnect (UInt16 btLibRefNum, BtLibDeviceAddressTypePtr remoteDeviceP)`

**Parameters** `-> btLibRefNum` Reference number for the Bluetooth library.

-> remoteDeviceP  
Pointer to a [BtLibDeviceAddressType](#) containing the address of the remote device.

**Result** Returns one of the following values:

btLibErrNoError  
The connection attempt was canceled before it started. No event is generated.

btLibErrPending  
When the link actually disconnects, a [btLibManagementEventAcldisconnect](#) callback event is generated.

btLibErrBusy  
Can't disconnect the link because the piconet is being destroyed.

btLibErrNoConnection  
No link to the specified device exists.

btLibErrNotOpen  
The referenced Bluetooth library is not open.

btLibErrStackNotOpen  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** When the link disconnects, a [btLibManagementEventAcldisconnect](#) event is generated.

**See Also** [BtLibLinkConnect](#)

## Bluetooth Library: Management

### Management Functions

---

## **New** BtLibLinkGetState

**Purpose** Get the state of an ACL link.

**Declared In** BtLib.h

**Prototype** Err BtLibLinkGetState(UInt16 btLibRefNum,  
BtLibDeviceAddressTypePtr remoteDeviceP,  
BtLibLinkPrefsEnum pref, void \*linkState,  
UInt16 linkStateSize)

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > remoteDeviceP  
Pointer to a [BtLibDeviceAddressType](#) containing the address of the remote device. This address identifies the ACL link.
- > pref Link preference to retrieve. See [BtLibLinkPrefsEnum](#).
- <- linkState Pointer to a buffer to store the value of the preference. You must allocate this buffer. This parameter must not be NULL. See [BtLibLinkPrefsEnum](#) for more information.
- > linkStateSize  
Size, in bytes, of linkState buffer. This size must match the size of the retrieved preference.

**Result** Returns one of the following values:

btLibErrNoError

Success. The linkState variable has been filled in.

btLibErrNoAclLink

No link to the specified remote device exists.

btLibErrNotOpen

The referenced Bluetooth library is not open.

`btLibErrParamError`

The `linkStateSize` parameter is not same as the size of the preference value.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** See the [BtLibLinkSetState](#) function description for a list of the link states preferences.

**See Also** [BtLibLinkSetState](#)

---

## ***New*** **BtLibLinkSetState**

**Purpose** Set the state of an ACL link

**Declared In** `BtLib.h`

**Prototype** `Err BtLibLinkSetState (UInt16 btLibRefNum, BtLibDeviceAddressTypePtr remoteDeviceP, BtLibLinkPrefsEnum pref, void *linkState, UInt16 linkStateSize)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `remoteDeviceP`  
The address of the remote device. This address identifies the ACL link.
- > `pref` Link preference to set. See [BtLibLinkPrefsEnum](#).
- > `linkState` Pointer to the value of the preference. This parameter must not be NULL. See [BtLibLinkPrefsEnum](#).

## Bluetooth Library: Management

### Management Functions

---

-> linkStateSize  
Size, in bytes, of the linkState value.

**Result** Returns one of the following values:

btLibErrPending  
The results will be returned through a callback event.

btLibErrFailed An attempt was made to encrypt a link before authenticating it.

btLibErrNoAclLink  
No link to the specified remote device exists.

btLibErrNotOpen  
The referenced Bluetooth library is not open.

btLibErrParamError  
The preference cannot be set or linkStateSize is invalid.

btLibErrStackNotOpen  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** Applications use this function to set the state of an ACL link. This function may generate events depending on the preference you change. The [btLibManagementEventAuthenticationComplete](#) event indicates the link authentication has completed. The [btLibManagementEventEncryptionChange](#) indicates that the encryption has been enabled or disabled.

#### BtLibLinkPrefsEnum

The BtLibLinkPrefsEnum enum specifies the link state preferences that can be accessed with the [BtLibLinkSetState](#) and [BtLibLinkGetState](#) functions.

```
typedef enum {  
    btLibLinkPref_Authenticated,  
    btLibLinkPref_Encrypted,  
    btLibLinkPref_LinkRole  
} BtLibLinkPrefsEnum;
```

### **Value Descriptions**

`btLibLinkPref_Authenticated`

This preference is a Boolean and indicates whether the link has been authenticated or not.

`btLibLinkPref_Encrypted`

This preference is a Boolean and indicates whether the link is encrypted or not.

`btLibLinkPref_LinkRole`

This preference is a [BtLibConnectionRoleEnum](#) and indicates whether the remote device is a master or a slave. You cannot set this preference but you can get its value.

**See Also** [BtLibLinkGetState](#)

---

## **New BtLibPiconetCreate**

**Purpose** Create a piconet or reconfigure an existing piconet so the local device is the master.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibPiconetCreate (UInt16 btLibRefNum, Boolean unlockInbound, Boolean discoverable)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `unlockInbound`  
If true, the piconet accepts inbound connections. Otherwise, the piconet only allows outbound connections.

## Bluetooth Library: Management

### Management Functions

---

-> discoverable

If `true`, configures the radio to be discoverable. In other words, the radio responds to inquiries. If `false`, configures the radio to be only connectable. In other words, only devices that know the radio's Bluetooth device address can connect to it. This parameter is ignored if `unlockInbound` is `false`.

**Result** Returns one of the following values:

`btLibErrNoError`

Successfully created the piconet with the local device as the master. No callback event is generated.

`btLibErrPending`

An existing ACL link needs to switch roles before this operation can complete.

`btLibErrFailed` A piconet already exists.

`btLibErrInProgress`

Another piconet is currently being created.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the accessibility of the radio changes due to this operation, a [btLibManagementEventAccessibilityChange](#) event is generated. When the piconet is created, or if the piconet fails to be created, a [btLibManagementEventPiconetCreated](#) event is generated. The `status` field of the [BtLibManagementEventType](#) structure accompanying the event indicates whether the piconet was created or not.

**See Also** [BtLibPiconetDestroy](#), [BtLibPiconetUnlockInbound](#), [BtLibPiconetLockInbound](#)

## **New** **BtLibPiconetDestroy**

**Purpose** Destroy the piconet by disconnecting links to all devices and removing all restrictions on whether the local device is a master or a slave.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibPiconetDestroy (UInt16 btLibRefNum)`

**Parameters** `-> btLibRefNum` Reference number for the Bluetooth library.

**Result** Returns one of the following values:

`btLibErrNoError`

Successfully destroyed the piconet. A [btLibManagementEventPiconetDestroyed](#) event is not generated.

`btLibErrPending`

The piconet is being destroyed, and a [btLibManagementEventPiconetDestroyed](#) event will be generated when the operation succeeds or fails.

`btLibErrBusy`

The piconet is already in the process of being destroyed.

`btLibErrNoPiconet`

No piconet exists to be destroyed.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** A [btLibManagementEventAcLDisconnect](#) event is generated for each ACL link that is disconnected. When the piconet is successfully destroyed or fails to be destroyed, a

## Bluetooth Library: Management

### Management Functions

---

[btLibManagementEventPiconetDestroyed](#) is generated. The `status` field of the [BtLibManagementEventType](#) structure accompanying the event indicates whether the piconet was destroyed or not.

**See Also** [BtLibPiconetCreate](#)

---

### **New** **BtLibPiconetLockInbound**

**Purpose** Prevent remote devices from creating ACL links into the piconet.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibPiconetLockInbound (UInt16 btLibRefNum)`

**Parameters** `-> btLibRefNum` Reference number for the Bluetooth library.

**Result** Returns one of the following values:

`btLibErrNoError`

Success.

`btLibErrBusy`

The piconet is in the process of being destroyed.

`btLibErrNoPiconet`

No piconet exists.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** After locking inbound connections, outbound connections are still allowed. Locking inbound connections maximizes the bandwidth for members of the piconet to transmit data to each other.

**See Also** [BtLibPiconetUnlockInbound](#)

---

## **BtLibPiconetUnlockInbound**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Allow remote devices to create ACL links into the piconet.                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Prototype</b>   | <code>Err BtLibPiconetUnlockInbound</code><br><code>(UInt16 btLibRefNum, Boolean discoverable)</code>                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <code>-&gt; btLibRefNum</code> Reference number for the Bluetooth library.<br><code>-&gt; discoverable</code><br>If <code>true</code> , configures the radio to be discoverable. In other words, the radio responds to inquiries. If <code>false</code> , configures the radio to be only connectable. In other words, only devices that know the radio's Bluetooth device address can connect to it.      |
| <b>Result</b>      | Returns one of the following values:<br><code>btLibErrNoError</code> Success.<br><code>btLibErrBusy</code> The piconet is in the process of being destroyed.<br><code>btLibErrNoPiconet</code> No piconet exists.<br><code>btLibErrNotOpen</code> The referenced Bluetooth library is not open.<br><code>btLibErrStackNotOpen</code> The Bluetooth stack failed to initialize when the library was opened. |

## Bluetooth Library: Management

### Management Functions

---

**Comments** Allowing inbound connections lowers the bandwidth available to transmit data between members of the piconet because the radio must periodically scan for incoming links.

**See Also** [BtLibPiconetLockInbound](#)

**New**

## BtLibRegisterManagementNotification

**Purpose** Register a callback function to process events generated by management functions.

**Declared In** BtLib.h

**Prototype** Err BtLibRegisterManagementNotification  
(UInt16 btLibRefNum,  
BtLibManagementProcPtr callbackP, UInt32 refCon)

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > callbackP Pointer to a callback procedure to register. This pointer must not be NULL. See [BtLibManagementCallback](#) for more information.
- > refCon Application-defined data to pass to the event handler.

**Result** Returns one of the following values:

btLibErrNoError  
Success.

btLibErrAlreadyRegistered  
The callback has already been registered with the management entity.

btLibErrNotOpen  
The referenced Bluetooth library is not open.

btLibErrParamError  
One or more parameters is invalid.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

`btLibErrTooMany`

There is no space available to store the callback. The management entity allows a maximum of 16 callbacks to be registered at a time.

**Comments** The management functions are asynchronous. That is, they return immediately and generate events when the task actually completes at a later time. To handle these events, you need to define a callback function with the same prototype as [BtLibManagementCallback](#). Then you need to register your callback function using `BtLibRegisterManagementNotification`. For examples of the callback events your callback function needs to handle, see the [Management Callback Events](#) section.

Applications should unregister their management callbacks before closing the Bluetooth library to prevent the callback table from overflowing. The callback table holds a maximum of 16 entries.

**See Also** [BtLibUnregisterManagementNotification](#)

**New**

---

## **BtLibSetGeneralPreference**

**Purpose** Set one of the general management preferences.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSetGeneralPreference  
(UInt16 btLibRefNum, BtLibGeneralPrefEnum pref,  
void *prefValue, UInt16 prefValueSize)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `pref` General preference to set. See [BtLibGeneralPreferenceEnum](#).

## Bluetooth Library: Management

### Management Functions

---

- > `prefValue` Pointer to the value of the preference. This parameter must not be NULL. See [BtLibGeneralPreferenceEnum](#).
- > `prefValueSize` Size, in bytes, of `prefValue`.

**Result** Returns one of the following values:

- `btLibErrNoError`  
Success.
- `btLibErrPending`  
The results will be returned through a notification.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrParamError`  
One or more parameters is invalid. Be sure that `prefValueSize` matches the size of the preference value.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** See the [BtLibGetGeneralPreference](#) function description for a list of the preferences.

This function may generate events depending on the preference you change. The [btLibManagementEventAccessibilityChange](#) event indicates that the accessibility of the local device has changed.

| -> btLibRefNum       | Reference number for the Bluetooth library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                                                       |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                             |
| -> timeout           | Time, in seconds, this inquiry is allowed to take. If the inquiry does not complete within this time, it is canceled. The actual time is rounded to the nearest multiple of 1.28 seconds. If you specify a timeout period larger than 60 seconds, this function acts as if you specified a timeout period of 60 seconds. If this parameter is 0, the timeout period defaults to 10.24 seconds as specified in the Generic Access Profile.                                                                                                                                                                                                                                                                                  |                 |                                                       |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                             |
| -> maxResp           | Maximum number of responses the inquiry accepts. | btLibErrBluetoothOff | The Bluetooth radio is off. The user can turn the radio on and off with a setting in the preferences panel.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                                                       |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                             |
| btLibErrInProgress   | Another inquiry is already in progress.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                 |                                                       |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |                    |                                                                                             |

## Bluetooth Library: Management

### Management Functions

---

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** The function performs a low-level Bluetooth inquiry, as opposed to a full device discovery. Specifically, inquiries started with this function only return the Bluetooth address and the class of the discovered device. This function does not have a user interface.

Every time a device is discovered, a [btLibManagementEventInquiryResult](#) callback event is generated. When the inquiry is complete, a [btLibManagementEventInquiryComplete](#) callback event is generated. If the application calls [BtLibCancelInquiry](#), a [btLibManagementEventInquiryCanceled](#) callback event is generated.

**See Also** [BtLibCancelInquiry](#)

**New**

---

## BtLibUnregisterManagementNotification

**Purpose** Unregister a previously registered management callback.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibUnregisterManagementNotification  
(UInt16 btLibRefNum,  
BtLibManagementProcPtr callbackP)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `callbackP` Pointer to the callback procedure to unregister. This pointer must not be NULL.

**Result** Returns one of the following values:

`btLibErrNoError` Success.

`btLibErrError` The callback referenced by `callbackP` has not been registered.

`btLibErrNotOpen` The referenced Bluetooth library is not open.

`btLibErrParamError` One or more parameters are invalid.

`btLibErrStackNotOpen` The Bluetooth stack failed to initialize when the library was opened.

**Comments** Applications should unregister their management callbacks before closing the library to prevent the callback table from overflowing. The callback table holds a maximum of 16 entries.

**See Also** [BtLibRegisterManagementNotification](#)

## Application-Defined Functions

This section describes the callback functions that handle management events. These functions are supplied by the developer and can be named anything.

## Bluetooth Library: Management

### Application-Defined Functions

---

## **New** BtLibManagementCallback

---

**Purpose** Signal the result of a Bluetooth management event. When the event takes place, this callback function is called.

**Declared In** BtLibTypes.h

**Prototype** void (\*BtLibManagementProcPtr)  
(BtLibManagementEventType \*mEvent, UInt32 refCon)

**Parameters**

- > mEvent [BtLibManagementEventType](#) structure containing the event parameters.
- > refCon General purpose integer which you can use to hold application-specific information. When you register the callback with the [BtLibRegisterManagementNotification](#) function, you can specify a value to pass to this parameter.

**Result** Returns nothing.

**Comments** The event and status of the event are in the mEvent structure. See [Management Callback Events](#) for more information.

You must register this function using the [BtLibRegisterManagementNotification](#) function before it starts receiving events.

# Bluetooth Library: Sockets and Service Discovery

---

The Bluetooth library uses sockets to represent L2CAP, RFCOMM, and SDP connections. This chapter presents reference material for the socket and SDP support provided by the Bluetooth library API:

## [Socket-Related Data Structures](#)

This section lists some of the more important types used by the Bluetooth library.

## [Socket Callback Events](#)

The Bluetooth library socket API supports L2CAP, RFCOMM, and SDP, the upper protocols of the Bluetooth specification. As with the management functions, the socket functions are mostly asynchronous. To signal to the application that socket operations have completed, the Bluetooth library generates *socket callback events* by calling a callback function.

## [Socket Disconnection Error Codes](#)

In addition to the standard error codes that can accompany socket events, the status codes accompanying the disconnection and connection events can have the additional values enumerated in this section.

## [Socket Functions](#)

The functions in this section perform general socket tasks and tasks related to L2CAP and RFCOMM sockets. The functions specific to SDP sockets are in the next section.

## Bluetooth Library: Sockets and Service Discovery

### Socket-Related Data Structures

---

#### [Service Discovery Protocol Functions](#)

This section describes functions and macros specific to the Bluetooth Service Discovery Protocol (SDP).

#### [Application-Defined Functions](#)

This section describes the callback functions that handle socket events.

The header file `BtLib.h` declares the Bluetooth library functions and macros. The header file `BtLibTypes.h` declares the data structures that you use with those functions and macros. For more information about using the Bluetooth library, see the *Palm OS Programmer's Companion Supplement: Bluetooth*.

## Socket-Related Data Structures

This section lists some of the more important types used by the Bluetooth library.

**New**

---

### **BtLibL2CapPsmType**

The `BtLibL2CapPsmType` type represents a Protocol and Server Multiplexer (PSM) value. See the “Logical Link and Adaptation Protocol Specification” chapter of the *Specification of the Bluetooth System* for more information about PSM values. The Bluetooth library only supports two-byte PSM values.

```
typedef UInt16 BtLibL2CapPsmType;
```

**New**

---

### **BtLibLanguageBaseTripletType**

The `BtLibLanguageBaseTripletType` structure represents a language base attribute identifier list attribute. See the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* for more information.

```
typedef struct BtLibLanguageBaseTripletType {  
    UInt16 naturalLanguageIdentifier;
```

```
    UInt16 characterEncoding;  
    UInt16 baseAttributeID;  
} BtLibLanguageBaseTripletType;
```

### Field Descriptions

naturalLanguageIdentifier

A UInt16 representing a natural language. See [Language Constants](#) for a set of constants that can be used in this field.

characterEncoding

A UInt16 representing a character set encoding. See [Character Encoding Constants](#) for a set of constants that can be used in this field.

baseAttributeID

Base attribute identifiers for attributes represented in this language. See [Attribute Identifier Offsets](#) for offsets that are added to this value to get the attribute identifiers for specific attributes represented in this language.

### Language Constants

These constants are used in the naturalLanguageIdentifier field of the BtLibLanguageBaseTripletType and are defined in the ISO 639:1988 specification.

### **Attribute Identifier Offsets**

`btLibServiceNameOffset`

The offset from the `baseAttributeID` to get the attribute identifier of the service name.

`btLibServiceDescriptionOffset`

The offset from the `baseAttributeID` to get the attribute identifier of the service description.

`btLibProviderNameOffset`

The offset from the `baseAttributeID` to get the attribute identifier of the provider name.

**New**

---

## **BtLibProfileDescriptorListEntryType**

The `BtLibProfileDescriptorListEntryType` structure represents an entry in a profile descriptor list attribute. See the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* for more information about profile descriptor list attributes.

```
typedef struct
    BtLibProfileDescriptorListEntryType {

        BtLibSdpUuidType profUUID;
        UInt16 version;
    } BtLibProfileDescriptorListEntryType;
```

### **Field Descriptions**

`profUUID`            The UUID of the profile.  
`version`             The version of the profile.

**New**

## BtLibProtocolDescriptorListEntryType

The `BtLibProtocolDescriptorListEntryType` structure represents an entry in a protocol descriptor list attribute. See the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* for more information.

```
typedef struct
    BtLibProtocolDescriptorListEntryType {

    BtLibSdpUuidType protoUUID;
    union {
        BtLibL2CapPsmType psm;
        BtLibRfCommServerIdType channel;
    } param;
} BtLibProtocolDescriptorListEntryType;
```

### Field Descriptions

|                        |                                                                                                                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>protoUUID</code> | The UUID of the protocol.                                                                                                                                                                                                                                                                           |
| <code>param</code>     | A union containing two members: <code>psm</code> and <code>channel</code> . <code>psm</code> is applicable for a L2CAP protocol descriptor and specifies the Protocol and Service Multiplexor. <code>channel</code> is applicable to a RFCOMM protocol descriptor and specifies the server channel. |

**New**

## BtLibRfCommServerIdType

The `BtLibRfCommServerIdType` type represents a RFCOMM server channel. See the “RFCOMM with TS 07.10” chapter of the *Specification of the Bluetooth System* for more information about server channels.

```
typedef UInt8 BtLibRfCommServerIdType;
```

**New**

---

## **BtLibSdpAttributeDataType**

The `BtLibSdpAttributeDataType` union is used to encapsulate an SDP attribute or a list entry in an SDP attribute. The [BtLibSdpServiceRecordGetAttribute](#) function gets an attribute or a list entry and return its contents in a `BtLibSdpAttributeDataType`. The [BtLibSdpServiceRecordSetAttribute](#) function sets an attribute or list entry according to the contents of a `BtLibSdpAttributeDataType`. This type supports the universal attributes defined in the *Specification of the Bluetooth System*.

```
typedef union BtLibSdpAttributeDataType {
    BtLibSdpUuidType serviceClassUuid;
    UInt32 serviceRecordState;
    BtLibSdpUuidType serviceIdUuid;
    BtLibProtocolDescriptorListEntryType
        protocolDescriptorListEntry;
    BtLibSdpUuidType browseGroupUuid;
    BtLibLanguageBaseTripletType
        languageBaseTripletListEntry;
    UInt32 timeToLive;
    UInt8 availability;
    BtLibProfileDescriptorListEntryType
        profileDescriptorListEntry;
    BtLibUrlType documentationUrl;
    BtLibUrlType clientExecutableUrl;
    BtLibUrlType iconUrl;
    BtLibStringType serviceName;
    BtLibStringType providerName;
} BtLibSdpAttributeDataType;
```

Note that if you're retrieving a string or a URL using the [BtLibSdpServiceRecordGetAttribute](#) function, you first need to allocate a buffer in addition to this union. This buffer must be large enough to contain the anticipated size of the string or URL. You must also initialize the string pointer and string length fields of the appropriate `BtLibAttributeDataType` union member. For

## Bluetooth Library: Sockets and Service Discovery

### Socket-Related Data Structures

---

example, if you're retrieving an icon URL, you need to set `iconURL.url` to point to the buffer. You also need to set `iconURL.urlLen` to the length of the buffer.

**See Also** [BtLibSdpUuidType](#),  
[BtLibProtocolDescriptorListEntryType](#),  
[BtLibProfileDescriptorListEntryType](#),  
[BtLibLanguageBaseTripletType](#), [BtLibUrlType](#),  
[BtLibStringType](#)

---

### **New** BtLibSdpAttributeIdType

The `BtLibSdpAttributeIdType` type represents a SDP attribute identifier.

```
typedef UInt16 BtLibSdpAttributeIdType;
```

The following constants are defined by the Bluetooth library. They represent the universal attributes in the *Specification of the Bluetooth System*.

#### **Universal Attribute IDs**

```
btLibServiceClassIdList  
btLibServiceRecordState  
btLibServiceId  
btLibProtocolDescriptorList  
btLibBrowseGroupList  
btLibLanguageBaseAttributeIdList  
btLibTimeToLive  
btLibAvailability  
btLibProfileDescriptorList  
btLibDocumentationUrl  
btLibClientExecutableUrl  
btLibIconUrl
```

## **BtLibSdpRecordHandle**

The `BtLibSdpRecordHandle` type, also called an *SDP memory handle*, provides a memory handle to an *SDP memory record*.

```
typedef MemHandle BtLibSdpRecordHandle;
```

A SDP memory record can have two roles: it can contain a local SDP service record or it can refer to an SDP service record on a remote device. In the latter role, the SDP memory record is said to be *mapped* to a service record on the remote device. The [BtLibSdpServiceRecordMapRemote](#) function performs this mapping.

## **BtLibSdpRemoteServiceRecordHandle**

The `BtLibSdpRemoteServiceRecordHandle` type represents a SDP service record handle on a remote device as defined in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*. The documentation refers to this type as a *remote service record handle*.

```
typedef UInt32  
    BtLibSdpRemoteServiceRecordHandle;
```

Note that this type is different from the [BtLibSdpRecordHandle](#) type, which refers to a memory chunk containing an SDP service record.

## **BtLibSdpUuidSizeEnum**

The `BtLibSdpUuidSizeEnum` enum specifies the sizes that a UUID can have. See [BtLibSdpUuidType](#) for more information.

```
typedef enum {  
    btLibUuidSize16 = 2,  
    btLibUuidSize32 = 4,  
    btLibUuidSize128 = 16  
} BtLibSdpUuidSizeEnum;
```

#### Value Descriptions

|                               |                        |
|-------------------------------|------------------------|
| <code>btLibUuidSize16</code>  | 16-bit UUID            |
| <code>btLibUuidSize32</code>  | 32-bit UUID            |
| <code>btLibUuidSize128</code> | Full size 128-bit UUID |

---

### BtLibSdpUuidType

The `BtLibSdpUuidType` structure represents a Universally Unique Identifier (UUID). A UUID is a 128-bit value that is generated in a manner that guarantees that it is different from every other UUID.

The “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System* reserves a set of UUIDs for common Bluetooth services and protocols. You can specify these with 32 bits—the remaining 96 bits have a fixed value. A subset of these can be specified with 16 bits zero-extended to 32 bits. Therefore you can specify a UUID using 16, 32, or 128 bits.

You generally don’t set this type directly. Instead, you use the [BtLibSdpUuidInitialize](#) macro.

```
typedef struct BtLibSdpUuidType {
    BtLibSdpUuidSizeEnum size;
    UInt8 UUID[16];
} BtLibSdpUuidType;
```

#### Field Descriptions

|                   |                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>size</code> | The number of bits used to specify the UUID. See <a href="#">BtLibSdpUuidSizeEnum</a> .                                 |
| <code>UUID</code> | The value of the UUID. If you’re setting the value of this field, use the <a href="#">BtLibSdpUuidInitialize</a> macro. |

### **Predefined UUIDs**

```
btLibSdpUUID_SC_SERVICE_DISCOVERY_SERVER
btLibSdpUUID_SC_BROWSE_GROUP_DESC
btLibSdpUUID_SC_PUBLIC_BROWSE_GROUP

```

## **New** BtLibSocketEventType

---

The `BtLibSocketEventType` structure contains detailed information regarding a socket callback event. All socket events have some common data. Most socket events have additional data specific to those events. The specific data is stored in a union that is part of the `BtLibSocketEvent` data structure.

```
typedef struct _BtLibSocketEventType {
    BtLibSocketEventEnum event;
    BtLibSocketRef socket;
    Err status;
    union
    {
        ...
    } eventData;
} BtLibSocketEventType,
*BtLibSocketEventTypePtr;
```

### Field Descriptions

|                        |                                                                                                                                                               |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>event</code>     | <code>BtLibSocketEventEnum</code> enum member that indicates which socket event has occurred. See <a href="#">Socket Callback Events</a> .                    |
| <code>socket</code>    | Socket associated with the event.                                                                                                                             |
| <code>status</code>    | Status of the event. The <a href="#">Socket Callback Events</a> section gives more details about how to interpret this field for specific events.             |
| <code>eventData</code> | Data associated with the event. The member of this union that is valid depends on the event. See <a href="#">Socket Callback Events</a> for more information. |

## **New** BtLibSocketRef

---

The `BtLibSocketRef` type identifies a socket.

```
typedef Int16 BtLibSocketRef;
```

  
**New**

---

### BtLibStringType

The `BtLibStringType` structure represents a string in an SDP attribute.

```
typedef struct BtLibStringType {
    Char *str;
    UInt16 strLen;
} BtLibStringType;
```

#### Field Descriptions

|                     |                                                                                    |
|---------------------|------------------------------------------------------------------------------------|
| <code>str</code>    | An array of characters representing the string. This array is not null-terminated. |
| <code>strLen</code> | The length of the string.                                                          |

  
**New**

---

### BtLibUrlType

The `BtLibUrlType` structure represents a uniform resource locator in an SDP attribute.

```
typedef struct BtLibUrlType {
    Char *url;
    UInt16 urlLen;
} BtLibUrlType;
```

#### Field Descriptions

|                     |                                                                                 |
|---------------------|---------------------------------------------------------------------------------|
| <code>url</code>    | An array of characters representing the URL. This array is not null-terminated. |
| <code>urlLen</code> | The length of the string.                                                       |

## Socket Callback Events

The Bluetooth library socket API supports L2CAP, RFCOMM, and SDP, the upper protocols of the Bluetooth specification. As with the

## Bluetooth Library: Sockets and Service Discovery

### Socket Callback Events

---

management functions, the socket functions are mostly asynchronous. To signal to the application that socket operations have completed, the Bluetooth library generates a *socket callback events* by calling a callback function.

You specify the callback function when you create a socket. When an event occurs, the callback function is called with two parameters: a pointer to a [BtLibSocketEventType](#) structure and a pointer to a user-defined structure.

The `BtLibSocketEventType` structure contains an event field, which indicates the reason the callback is called, a status field, which indicates status information associated with the event, a socket field, which indicates the socket associated with the event, and a union of several structures. The member of the union that is valid depends on the event. The meaning of the events is described in the following sections.

### **btLibSocketEventConnectedInbound**

A remote connection has been accepted because the application has called [BtLibSocketRespondToConnection](#).

For this event, the `eventData` field contains the following field:

```
BtLibSocketRef newSocket;
```

This [BtLibSocketRef](#) contains the reference to the new socket.

If the remote device requests a L2CAP connection, this event is sent to the L2CAP listener socket with a PSM that matches the PSM of the requested connection. The Bluetooth library creates a new socket that exchanges data with the remote device.

If the remote device requests an RFCOMM connection, this event is sent to the RFCOMM listener socket with a server channel that matches the server channel of the requested connection. The Bluetooth library converts the listener socket into socket that exchanges data with the remote device.

### **btLibSocketEventConnectedOutbound**

An outbound connection initiated by a call to [BtLibSocketConnect](#) has completed. The status field is

`btLibErrNoError` if the connection has completed successfully. Otherwise, the `status` field indicates why the connection failed.

### **btLibSocketEventConnectRequest**

A remote device has requested a connection.

You must respond to this event with a call to [BtLibSocketRespondToConnection](#).

For this event, the `eventData` field contains the following field:

```
BtLibDeviceAddressType requestingDevice;
```

This [BtLibDeviceAddressType](#) contains the address of the remote device requesting the connection.

If the remote device requests a L2CAP connection, this event is sent to the L2CAP listener socket with a PSM that matches the PSM of the request.

If the remote device requests an RFCOMM connection, this event is sent to the RFCOMM listener socket with a server channel that matches the server channel of the request.

To convert a socket into a listener socket use the [BtLibSocketListen](#) function.

### **btLibSocketEventData**

Data has been received on a socket.

For this event, the `eventData` field contains the following structure:

```
struct {
    UInt16 dataLen;
    UInt8 *data;
} data;
```

#### **Value Descriptions**

`dataLen`            The size, in bytes, of the received data.

`data`                A pointer to the received data.

## btLibSocketEventDisconnected

The connection has been lost or one of the devices has disconnected. The socket is now invalid. The `status` field indicates the reason for the disconnection.

## btLibSocketEventSdpServiceRecordHandle

A request for remote service records matching a list of service classes has completed. The application initiated this request by calling the [BtLibSdpServiceRecordsGetByServiceClass](#) function.

If the `status` field is `btLibErrNoError`, the SDP operation completed successfully, and the `eventData` field contains valid information. Otherwise the SDP operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    UInt16 numSrvRec;
    BtLibSdpRemoteServiceRecordHandle
        *serviceRecordList;
} sdpServiceRecordHandles;
```

### Value Descriptions

`numSrvRec`            Number of remote service record handles in the returned array.

`serviceRecordList`  
An array of [BtLibSdpRemoteServiceRecordHandles](#) for the service records matching the service class list.

## btLibSocketEventSdpGetAttribute

An attribute request has completed. The application initiated this request by calling the [BtLibSdpServiceRecordGetAttribute](#) function.

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the `eventData` field contains valid data. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

### Value Descriptions

|                          |                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------|
| <code>attributeID</code> | The attribute identifier of the attribute.                                                 |
| <code>recordH</code>     | A handle identifying the SDP memory record from which the attribute is retrieved.          |
| <code>info</code>        | A union containing information specific to the event. See <a href="#">The info Field</a> . |

### The info Field

For this event, the `info` field contains the following structure:

```
struct {
    BtLibSdpAttributeDataType *attributeValues;
    UInt16 listNumber;
    UInt16 listEntry;
} data;
```

### Value Descriptions

|                              |                                                                                                                                                   |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>attributeValues</code> | A <a href="#">BtLibSdpAttributeDataType</a> containing the value of the attribute or list entry.                                                  |
| <code>listNumber</code>      | The index of the list in which this list entry appears or 0 if the attribute is not a protocol descriptor list. The index of the first list is 0. |

## Bluetooth Library: Sockets and Service Discovery

### Socket Callback Events

---

`listEntry`

The index of the list entry within the list or 0 if the attribute is not a list. The index of the first entry is 0.

### **btLibSocketEventSdpGetStringLen**

A string or URL length request has completed. The application initiated this request by calling

[BtLibSdpServiceRecordGetStringOrUrlLength](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and `length` can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

#### **Value Descriptions**

`attributeID` The attribute identifier of the attribute.

`recordH` A handle identifying the SDP memory record from which the string length is retrieved.

`info` A union containing information specific to the event. See [The info Field](#).

#### **The info Field**

For this event, the `info` field contains the following field:

```
UInt16 strLength;
```

This field contains the length of the string or URL represented by the attribute. Bluetooth strings and URLs are not null-terminated.

## **btLibSocketEventSdpGetNumListEntries**

A number of list entries request has completed. The application initiated this request by calling

[BtLibSdpServiceRecordGetNumListEntries](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the number of list entries can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

### **Value Descriptions**

|                          |                                                                                                |
|--------------------------|------------------------------------------------------------------------------------------------|
| <code>attributeID</code> | The attribute identifier of the attribute.                                                     |
| <code>recordH</code>     | A handle identifying the SDP memory record from which the number of list entries is retrieved. |
| <code>info</code>        | A union containing information specific to the event. See <a href="#">The info Field</a> .     |

### **The info Field**

For this event, the `info` field contains the following field:

```
UInt16 numItems;
```

This field contains the number of entries in the list attribute.

## **btLibSocketEventSdpGetNumLists**

A number of lists request has completed. The application initiated this request by calling [BtLibSdpServiceRecordGetNumLists](#).

## Bluetooth Library: Sockets and Service Discovery

### Socket Callback Events

---

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the number of lists can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

#### Value Descriptions

|                          |                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------|
| <code>attributeID</code> | The attribute identifier of the attribute.                                                 |
| <code>recordH</code>     | A handle identifying the SDP memory record from which the number of lists is retrieved.    |
| <code>info</code>        | A union containing information specific to the event. See <a href="#">The info Field</a> . |

#### The info Field

For this event, the `info` field contains the following field:

```
UInt16 numItems;
```

This field contains the number of lists in the protocol list descriptor attribute.

### btLibSocketEventSdpGetRawAttribute

A get raw attribute request has completed. The application initiated the request by calling [BtLibSdpServiceRecordGetRawAttribute](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the raw attribute can be found in the `eventData` field. Otherwise the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

### Value Descriptions

|                          |                                                                                            |
|--------------------------|--------------------------------------------------------------------------------------------|
| <code>attributeID</code> | The attribute identifier of the attribute.                                                 |
| <code>recordH</code>     | A handle identifying the SDP memory record from which the raw attribute is retrieved.      |
| <code>info</code>        | A union containing information specific to the event. See <a href="#">The info Field</a> . |

### The info Field

For this event, the `info` field contains the following structure:

```
struct {
    UInt16 valSize;
    UInt8 *value;
} rawData;
```

### Value Descriptions

|                      |                                                       |
|----------------------|-------------------------------------------------------|
| <code>valSize</code> | Number of size, in bytes, of the raw attribute value. |
| <code>value</code>   | Byte array containing the raw attribute value.        |

## **btLibSocketEventSdpGetRawAttributeSize**

A get raw attribute size request has completed. The application initiated this request by calling

[BtLibSdpServiceRecordGetSizeOfRaw Attribute](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the size of the attribute can be found in the

## Bluetooth Library: Sockets and Service Discovery

### Socket Callback Events

---

eventData field. Otherwise the operation failed, and the status field indicates the reason for the failure.

For this event, the eventData field contains the following structure:

```
struct {
    BtLibSdpAttributeIdType attributeID;
    BtLibSdpRecordHandle recordH;
    union {
        ...
    } info;
} sdpAttribute;
```

#### Value Descriptions

|             |                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------|
| attributeID | The attribute identifier of the attribute.                                                        |
| recordH     | A handle identifying the SDP memory record from which the size of the raw attribute is retrieved. |
| info        | A union containing information specific to the event. See <a href="#">The info Field</a> .        |

#### The info Field

For this event, the info field contains the following field:

```
UInt16 valSize;
```

This field contains the size, in bytes, of the raw attribute value.

### **btLibSocketEventSdpGetServerChannelByUuid**

A get server channel request has completed. The application initiated this request by calling [BtLibSdpGetServerChannelByUuid](#).

If the status field is `btLibErrNoError`, the operation completed successfully, and the server channel can be found in the eventData field. Otherwise, the operation failed, and the status field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpRemoteServiceRecordHandle
        remoteHandle;
    union {
        ...
    } param;
} sdpByUuid;
```

### Value Descriptions

|                           |                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------|
| <code>remoteHandle</code> | The handle for the remote SDP service record.                                                   |
| <code>param</code>        | A union containing information that depends on the event. See <a href="#">The param Field</a> . |

### The param Field

For this event, the `param` field contains the following field:

```
BtLibRfCommServerIdType channel;
```

This [BtLibRfCommServerIdType](#) contains the RFCOMM server channel represented by the SDP service record.

## btLibSocketEventSdpGetPsmByUuid

A get PSM request has completed. The application initiated this request by calling [BtLibSdpGetPSMByUuid](#).

If the `status` field is `btLibErrNoError`, the operation completed successfully, and the server channel can be found in the `eventData` field. Otherwise, the operation failed, and the `status` field indicates the reason for the failure.

For this event, the `eventData` field contains the following structure:

```
struct {
    BtLibSdpRemoteServiceRecordHandle
        remoteHandle;
    union {
        ...
    } param;
}
```

## Bluetooth Library: Sockets and Service Discovery

### Socket Callback Events

---

```
    } sdpByUuid;
```

#### Value Descriptions

`remoteHandle` The handle for the remote SDP service record.

`param` A union containing information that depends on the event. See [The param Field](#).

#### The param Field

For this event, the `param` field contains the following field:

```
BtLibL2CapPsmType psm;
```

This [BtLibL2CapPsmType](#) contains the PSM value of the L2CAP channel represented by the SDP service record.

## btLibSocketEventSendComplete

A send request has completed. The application initiated this request by calling [BtLibSocketSend](#).

For this event, the `eventData` field contains the following structure:

```
struct {
    UInt16 dataLen;
    UInt8 *data;
} data;
```

#### Value Descriptions

`dataLen` The number of bytes of data that were actually sent.

`data` Not used. This variable does not contain any valid information.

#### Error Conditions

`btLibErrNoError` Success.

`btLibErrNoAclLink` No ACL Link.

## Socket Disconnection Error Codes

In addition to the standard error codes that can accompany socket events, the status codes accompanying the [btLibSocketEventConnectedInbound](#), [btLibSocketEventConnectedOutbound](#), and [btLibSocketEventDisconnected](#) events can have the following additional values:

- `btLibL2DiscConfigOptions`  
Configuration failed due to an unrecognized configuration option.
- `btLibL2DiscConfigReject`  
Configuration was rejected (unknown reason).
- `btLibL2DiscConfigUnacceptable`  
Configuration failed due to unacceptable parameters.
- `btLibL2DiscConnNoResources`  
The remote device is out of resources.
- `btLibL2DiscConnPsmUnsupported`  
The remote device does not support the requested protocol service (PSM).
- `btLibL2DiscConnSecurityBlock`  
The remote device's security system denied the connection.
- `btLibL2DiscLinkDisc`  
The underlying ACL Link was disconnected.
- `btLibL2DiscQosViolation`  
The connection was terminated due to a Quality of Service (QOS) violation.
- `btLibL2DiscReasonUnknown`  
Disconnection occurred for an unknown reason.
- `btLibL2DiscRequestTimeout`  
An L2CAP request timed out.

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

`btLibL2DiscSecurityBlock`

The local security manager refused the connection attempt.

`btLibL2DiscUserRequest`

Disconnection was requested by either the local or remote device.

## Socket Functions

The Bluetooth library uses sockets to represent L2CAP, RFCOMM, and SDP connections. The functions in this section perform general socket tasks and tasks related to L2CAP and RFCOMM sockets. The functions specific to SDP sockets are in the [Service Discovery Protocol Functions](#) section.

**New**

---

### BtLibSocketAdvanceCredit

**Purpose** Advance credit to a given RFCOMM connection socket.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSocketAdvanceCredit (UInt16 btLibRefNum, BtLibSocketRef socket, UInt8 credit)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` RFCOMM socket reference number.
- > `credit` Number credits to add to the total number of credits for this socket. The total number of credits represents the number of packets the remote device can send before data flow stops.

**Result** Returns one of the following values:

`btLibErrNoError`

Success

`btLibErrFailed` Too many credits advanced.

`btLibErrSocket` The specified socket is invalid.

`btLibErrSocketProtocol`

The specified socket is not an RFCOMM socket.

`btLibErrSocketRole`

The specified socket is not connected.

**Comments** RFCOMM uses a credit based flow control mechanism. For each credit the connection has, one packet of data can be sent. When the credits are spent, data flow stops until you advance more credits using this function.

Multiple calls to this function have a cumulative effect.

**New**

---

## BtLibSocketClose

**Purpose** Close a socket, free associated resources, and kill all associated socket connections.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSocketClose (UInt16 btLibRefNum, BtLibSocketRef socket)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number of socket to close.

**Result** Returns one of the following values:

`btLibErrNoError`

Success.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrSocket`

The specified socket is invalid.

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** No callback events are generated when closing a socket.

**See Also** [BtLibSocketCreate](#), [BtLibSocketListen](#),  
[BtLibSocketConnect](#), [BtLibSocketRespondToConnection](#)

---

### **New** BtLibSocketConnect

**Purpose** Create an outbound L2CAP or RFCOMM connection.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSocketConnect (UInt16 btLibRefNum,  
BtLibSocketRef socket,  
BtLibSocketConnectInfoType *connectInfo)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number of socket to connect.
- > `connectInfo` [BtLibSocketConnectInfoType](#) containing Bluetooth device address and protocol-specific connection information.

**Result** Returns one of the following values:

`btLibErrPending`

The results will be returned through a callback event.

`btLibErrNoAclLink`

An ACL link for the remote device does not exist

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrSocket` The specified socket is invalid.

`btLibErrSocketProtocol`

The protocol of the specified socket is not supported. This function only supports the L2CAP and RFCOMM protocols.

`btLibErrSocketRole`

The specified socket is already connected or listening.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

### Comments

If the connection succeeds, the `btLibSocketEventConnectedOutbound` event is generated and its `status` field is set to `btLibErrNoError`. If connection fails, the same event is generated with a non-zero `status` field, or a `btLibSocketEventDisconnected` is generated. In both cases, the `status` field indicates the reason for the failure.

If the connection succeeds, the `btLibSocketEventData` event is generated whenever data is received from the remote device. When the channel disconnects, a `btLibSocketEventDisconnected` event is generated.

### BtLibSocketConnectInfoType

The `BtLibSocketConnectInfoType` structure allows you to specify the address of the remote device and data specific to the protocol of the socket. The protocol-specific data is stored as a union; the member of the union that is valid depends on the protocol.

```
typedef struct BtLibSocketConnectInfoType {
    BtLibDeviceAddressTypePtr remoteDeviceP;
    union {
        ...
    } data;
} BtLibSocketConnectInfoType;
```

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

#### Field Description

|               |                                                                                                                                    |
|---------------|------------------------------------------------------------------------------------------------------------------------------------|
| remoteDeviceP | A pointer to a <a href="#">BtLibDeviceAddressType</a> that contains the address of the remote device.                              |
| data          | A union containing protocol-specific information. This union has two members: <a href="#">L2Cap</a> , and <a href="#">RfComm</a> . |

#### L2Cap

Use the L2Cap union member if you're setting up a L2CAP socket. This member contains the following structure:

```
struct {
    BtLibL2CapPsmType remotePsm;
    UInt16 minRemoteMtu;
    UInt16 localMtu;
} L2Cap;
```

#### Field Descriptions

|              |                                                                                                                                                                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| remotePsm    | A <a href="#">BtLibL2CapPsmType</a> representing the protocol and service multiplexer (PSM) identifier of the protocol to which this socket should connect. This identifier is obtained using the Service Discovery Protocol (SDP). |
| minRemoteMtu | The minimum MTU, or packet size, that your application can support.                                                                                                                                                                 |
| localMtu     | The MTU, or packet size, of the local device.                                                                                                                                                                                       |

#### RfComm

Use the RfComm union member if you're setting up a RFCOMM socket. This member contains the following structure:

```
struct {
    BtLibRfCommServerIdType remoteService;
    UInt16 maxFrameSize;
    UInt8 advancedCredit;
} RfComm;
```

#### Field Descriptions

|                             |                                                                                                                                                                                                                                                              |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>remoteService</code>  | A <a href="#">BtLibRfCommServerIdType</a> representing the RFCOMM service channel on the remote device to which this socket should connect. This identifier is obtained using the Service Discovery Protocol (SDP).                                          |
| <code>maxFrameSize</code>   | The maximum frame size your application can handle. This value must be between <code>BT_RF_MINFRAMESIZE</code> and <code>BT_RF_MAXFRAMESIZE</code> . If your application can handle any frame size, set this value to <code>BT_RF_DEFAULT_FRAMESIZE</code> . |
| <code>advancedCredit</code> | An amount of credit the socket advances to the remote device when it successfully connects. Additional credit can be advanced using the <a href="#">BtLibSocketAdvanceCredit</a> function once the connection has been established.                          |

**See Also** [BtLibSocketSend](#), [BtLibSocketClose](#)

---

## **New** BtLibSocketCreate

**Purpose** Create a socket with foreground notification. The Bluetooth library supports a maximum of 16 socket connections.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSocketCreate (UInt16 btLibRefNum,
BtLibSocketRef *socketRefP,
BtLibSocketProcPtr callbackP, UInt32 refCon,
BtLibProtocolEnum socketProtocol)
```

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- <- `socketRefP` Pointer to an allocated [BtLibSocketRef](#) that contains the socket value upon return. This pointer must not be NULL.

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

- > `callbackP`      Callback procedure used to respond to socket events. This value must not be NULL.
- > `refCon`          Caller-defined data to pass to the callback procedure.
- > `socketProtocol`      Protocol (L2CAP, RFCOMM, or SDP) to use with this socket.

**Result**      Returns one of the following values:

- `btLibErrNoError`  
Success.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrParamError`  
Either `socketRefP` or `callbackP` is NULL.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.
- `btLibErrTooMany`  
The maximum number of sockets allocated for the system has already been reached. The Bluetooth library supports a maximum of 16 socket connections.

**Comments**      No callback events are generated when creating a socket.  
Before terminating, applications should close all of the sockets that they have created.

**See Also**      [BtLibSocketConnect](#), [BtLibSocketListen](#),  
[BtLibSocketClose](#)

## **New** BtLibSocketGetInfo

---

**Purpose** Retrieve information for a currently open socket.

**Declared In** BtLib.h

**Prototype** `Err BtLibSocketGetInfo (UInt16 btLibRefNum,  
BtLibSocketRef socket,  
BtLibSocketInfoEnum infoType, void *valueP,  
UInt32 valueSize)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number for the socket to query.
- > `infoType` Type of information to retrieve. See [BtLibSocketInfoEnum](#).
- <- `valueP` Buffer into which this function stores the result. You must allocate this buffer.
- > `valueSize` Size, in bytes, of the `valueP` buffer. This size must match the size of the retrieved information.

**Result** Returns one of the following values:

`btLibErrNoError`  
Success.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrParamError`  
One or more parameters is invalid. Be sure that the `valueSize` parameter matches the size of the information you're retrieving.

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

- `btLibErrSdpNotMapped`  
The SDP socket has not been mapped to a remote SDP service record. This error occurs when you try to obtain the SDP service record handle before you map socket to a remote service record using [BtLibSdpServiceRecordMapRemote](#).
- `btLibErrSocket` The specified socket is invalid or not in use.
- `btLibErrSocketRole`  
The specified socket is not connected or has the wrong role for the request.
- `btLibErrSocketProtocol`  
The specified socket has the wrong protocol for the request.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

#### Comments **BtLibSocketInfoEnum**

The `BtLibSocketInfoEnum` enum allows you to specify which information you want to retrieve using the [BtLibSocketGetInfo](#) function.

```
typedef enum {
    btLibSocketInfo_Protocol = 0,
    btLibSocketInfo_RemoteDeviceAddress,
    btLibSocketInfo_SendPending = 100,
    btLibSocketInfo_MaxTxSize,
    btLibSocketInfo_MaxRxSize,
    btLibSocketInfo_L2CapPsm = 200,
    btLibSocketInfo_L2CapChannel,
    btLibSocketInfo_RfCommServerId = 300,
    btLibSocketInfo_RfCommOutstandingCredits,
    btLibSocketInfo_SdpServiceRecordHandle = 400
} BtLibSocketInfoEnum;
```

### Value Descriptions

`btLibSocketInfo_L2CapChannel`

`BtLibSocketGetInfo` returns a `BtLibL2CapChannelIDType` that represents the channel identifier for this socket. A `BtLibL2CapChannelIDType` is actually a `UInt16`. This information is valid for L2CAP sockets only. See the “Logical Link Control and Adaptation Protocol Specification” chapter of the *Specification of the Bluetooth System* for more information about channel identifiers.

`btLibSocketInfo_L2CapPsm`

`BtLibSocketGetInfo` returns a [BtLibL2CapPsmType](#) that represents the Protocol and Service Multiplexer (PSM) this socket is using to route packets. This information is only valid for L2CAP sockets.

`btLibSocketInfo_MaxRxSize`

`BtLibSocketGetInfo` returns a `UInt32` representing the maximum packet size the local device can receive.

`btLibSocketInfo_MaxTxSize`

`BtLibSocketGetInfo` returns a `UInt32` representing the maximum packet size the local device can transmit.

`btLibSocketInfo_Protocol`

`BtLibSocketGetInfo` returns a `BtLibProtocolEnum` representing the socket’s protocol. The members of this enum are `btLibL2CapProtocol`, `btLibRfCommProtocol`, and `btLibSdpProtocol`.

`btLibSocketInfo_RemoteDeviceAddress`

`BtLibSocketGetInfo` returns a [BtLibDeviceAddressType](#) representing the address of the device at the other end of this socket.

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

`btLibSocketInfo_RfCommServerId`  
BtLibSocketGetInfo returns a [BtLibRfCommServerIdType](#) that represents the socket's RFCOMM server channel. This information is valid for RFCOMM sockets only.

`btLibSocketInfo_RfCommOutstandingCredits`  
BtLibSocketGetInfo returns a `UInt16` containing the number of remaining credits on this socket. This information is valid for RFCOMM sockets only.

`btLibSocketInfo_SdpServiceRecordHandle`  
BtLibSocketGetInfo returns the [BtLibSdpRemoteServiceRecordHandle](#) for the service record associated with this socket. This information is valid for SDP sockets only.

`btLibSocketInfo_SendPending`  
BtLibSocketGetInfo returns a `Boolean` indicating whether a send is currently in progress.

**New**

---

## BtLibSocketListen

**Purpose** Set up an L2CAP or RFCOMM socket as a listener.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSocketListen (UInt16 btLibRefNum, BtLibSocketRef socket, BtLibSocketListenInfoType *listenInfo)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number of the socket.

`<-> listenInfo` Protocol-specific listening information. For more information see [BtLibSocketListenInfoType](#). This parameter must not be NULL.

**Result** Returns one of the following values:

`btLibErrNoError` Success. The socket is listening for incoming connections.

`btLibErrBusy` The given PSM is in use (L2CAP only)

`btLibErrNotOpen` The referenced Bluetooth library is not open.

`btLibErrParamError` `listenInfo` is NULL.

`btLibErrSocket` The specified socket is invalid.

`btLibErrSocketProtocol` The protocol of the specified socket is not supported. This function only supports the L2CAP and RFCOMM protocols.

`btLibErrSocketRole` The specified socket is already listening or connected.

`btLibErrStackNotOpen` The Bluetooth stack failed to initialize when the library was opened.

`btLibErrTooMany` There are no resources to create a listener socket of this type.

**Comments** A listener socket waits for a remote device to initiate a connection to the local device and then generates a [btLibSocketEventConnectRequest](#) event to notify the application that it needs to handle the connection attempt.

You need to respond to this event with a call to [BtLibSocketRespondToConnection](#) on the listener socket to accept or reject the connection.

## Bluetooth Library: Sockets and Service Discovery

### Socket Functions

---

Under certain circumstances, the `listenInfo` parameter acts as an output as well as an input. See the documentation for `BtLibSocketListenInfoType` that follows.

#### **BtLibSocketListenInfoType**

The `BtLibSocketListenInfoType` structure allows you to specify data specific to the protocol of the listening socket.

```
typedef struct BtLibSocketListenInfoType {
    union {
        ...
    } data;
} BtLibSocketListenInfoType;
```

This data is stored in the `data` field, which is a union consisting of two members: [L2Cap](#), and [RfComm](#). The member of the union that is valid depends on the protocol of the listening socket.

#### **L2Cap**

Use the `L2Cap` union member if you're setting up a L2CAP socket as a listener. This member contains the following structure:

```
struct {
    BtLibL2CapPsmType localPsm;
    UInt16 localMtu;
    UInt16 minRemoteMtu;
} L2Cap;
```

#### **Field Descriptions**

`localPsm`      A [BtLibL2CapPsmType](#) representing the protocol and service multiplexer (PSM) identifier of the protocol to be used with this socket. You can identify your own protocol provided that its PSM value is odd, is within the range of 0x1001 to 0xFFFF, and has the 9th bit (0x0100) set to zero. These limitations are specified by the *Specification of the Bluetooth System*. If you set this field to `BT_L2CAP_RANDOM_PSM`, the `BtLibSocketListen` function automatically creates a suitable PSM for the channel and returns it in this structure.

|              |                                                                           |
|--------------|---------------------------------------------------------------------------|
| localMtu     | The maximum transmission unit (MTU), or packet size, of the local device. |
| minRemoteMtu | The minimum packet size that your application can support.                |

### **RfComm**

Use the `RfComm` union member if you're setting up a RFCOMM socket as a listener. This member contains the following structure:

```
struct {
    BtLibRfCommServerIdType serviceID;
    UInt16 maxFrameSize;
    UInt8 advancedCredit;
} RfComm;
```

### **Field Descriptions**

|                |                                                                                                                                                                                                                                                              |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| serviceID      | A <a href="#">BtLibRfCommServerIdType</a> representing the socket's RFCOMM service channel. It is assigned by RFCOMM and returned in this field when you call <code>BtLibSocketListen</code> .                                                               |
| maxFrameSize   | The maximum frame size your application can handle. This value must be between <code>BT_RF_MINFRAMESIZE</code> and <code>BT_RF_MAXFRAMESIZE</code> . If your application can handle any frame size, set this value to <code>BT_RF_DEFAULT_FRAMESIZE</code> . |
| advancedCredit | An amount of credit the socket advances to the remote device when it successfully connects. Additional credit can be advanced using the <a href="#">BtLibSocketAdvanceCredit</a> function once the connection has been established.                          |

**See Also** [BtLibSocketClose](#)

### **New** **BtLibSocketRespondToConnection**

**Purpose** Accept or reject an in-bound connection on a given listener socket.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSocketRespondToConnection  
(UInt16 btLibRefNum, BtLibSocketRef socket,  
Boolean accept)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number of the listener socket.
- > `accept` `true` to accept the connection; `false` to reject the connection.

**Result** Returns one of the following values:

`btLibErrNoError` Success. This status is returned when `accept` is `false`.

`btLibErrFailed` One or more parameters is invalid.

`btLibErrPending` The results will be returned through a callback event.

`btLibErrNotOpen` The referenced Bluetooth library is not open.

`btLibErrSocket` The specified socket is invalid or not in use.

`btLibErrSocketProtocol` The protocol of the specified socket is not supported. This function only supports the L2CAP and RFCOMM protocols.

`btLibErrSocketRole` The specified socket is not a listener socket.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You should call this function when you respond to a [btLibSocketEventConnectRequest](#) event delivered to a listener socket.

If the connection succeeds, the [btLibSocketEventConnectedInbound](#) event is generated and its `status` field is set to `btLibErrNoError`. If connection fails, the same event is generated with a non-zero `status` field, or a [btLibSocketEventDisconnected](#) is generated. In both cases, the `status` field indicates the reason for the failure.

Once the connection succeeds, a [btLibSocketEventData](#) callback event is generated whenever data received from the remote device. If the channel disconnects, a [btLibSocketEventDisconnected](#) is generated.

RFCOMM listener sockets and L2CAP listener sockets behave differently when you call this function. When you respond to an inbound L2CAP connection, a new L2CAP socket is created to exchange data with the remote device, and the L2CAP listener socket continues to listen for more connections. In other words, a single L2CAP listener socket can “spawn” several L2CAP sockets. This mechanism allows you to create a piconet.

On the other hand, when you respond to an RFCOMM connection, the RFCOMM listener socket becomes a connection socket through which you can exchange data with the remote device. If you want to create another RFCOMM connection, you need to create another listener socket.

`btLibErrSocket` The specified socket is invalid.

`btLibErrSocketProtocol`

The protocol of the specified socket is not supported by this function. You can only send using the L2CAP and RFCOMM protocols.

`btLibErrSocketRole`

The specified socket is not connected.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**

When the data has been sent successfully, a [btLibSocketEventSendComplete](#) callback event is generated and its `status` field is set to `btLibErrNoError`. If the data is not sent successfully, the same callback event is generated with a non-zero `status` field.

Note that there can be only one send in progress at a time per socket. You must wait for the [btLibSocketEventSendComplete](#) event before sending another packet.

**See Also** [BtLibSocketClose](#)

## Service Discovery Protocol Functions

This section describes functions and macros related to the Bluetooth Service Discovery Protocol (SDP).

## **New** BtLibSdpCompareUuids

---

**Purpose** Compare two UUIDs.

**Declared In** BtLib.h

**Prototype** `Err BtLibSdpCompareUuids (UInt16 btLibRefNum, BtLibSdpUuidType *uuid1, BtLibSdpUuidType *uuid2)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth Library.
- > `uuid1` UUID to compare.
- > `uuid2` UUID to compare.

**Result** Returns one of the following values:

`btLibErrNoError`  
UUIDs are the same

`btLibErrError` UUIDs are different.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrParamError`  
One or both UUIDs are invalid.

`btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

---

## **New** **BtLibSdpGetPSMByUuid**

| <b>Result</b>      | Returns one of the following values: <ul style="list-style-type: none"><li>btLibErrPending<br/>The PSM value will be returned through a<br/>callback event.</li><li>btLibErrNotOpen<br/>The referenced Bluetooth library is not open.</li><li>btLibErrOutOfMemory<br/>Not enough memory to complete request</li><li>btLibErrParamError<br/>One or more parameters is invalid.</li></ul>                                                                                                                                     |

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

`btLibErrSocket` The specified socket is invalid or not in use.

`btLibErrSocketRole`

The specified socket is not connected.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function returns the L2CAP PSM of the first SDP record on the remote device that contains all the specified UUIDs.

This function generates a [btLibSocketEventSdpGetPsmByUuid](#) event when the query completes or fails.

**See Also** [BtLibSdpGetServerChannelByUuid](#)

**New**

---

## BtLibSdpGetRawDataElementSize

**Purpose** Macro that returns a constant representing the data element's size.

**Declared In** `BtLib.h`

**Prototype** `BtLibSdpGetRawDataElementSize` (header)

**Parameters** `-> header` First byte of a data element

**Result** A constant representing the size of the data element.

**Comments** The first byte of a SDP data element contains the type and size of the data element.

The result of this macro is one of the following constants:

### Data Element Sizes

`btLibDESD_1BYTE`

A 1-byte element. However, if the data element's type is `btLibDETD_NIL` then the size is 0 bytes.

`btLibDESD_2BYTES`  
A 2-byte element.

`btLibDESD_4BYTES`  
A 4-byte element.

`btLibDESD_8BYTES`  
An 8-byte element.

`btLibDESD_16BYTES`  
A 16-byte element.

`btLibDESD_ADD_8BITS`  
The element's actual data size, in bytes, is contained in the next 8 bits.

`btLibDESD_ADD_16BITS`  
The element's actual data size, in bytes, is contained in the next 16 bits.

`btLibDESD_ADD_32BITS`  
The element's actual data size, in bytes, is contained in the next 32 bits.

These size constants are discussed in greater detail in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

**See Also** [BtLibSdpGetRawDataElementType](#),  
[BtLibSdpParseRawDataElement](#),  
[BtLibSdpVerifyRawDataElement](#)

## **New** **BtLibSdpGetRawDataElementType**

**Purpose** Macro that returns an SDP data element's type.

**Declared In** `BtLib.h`

**Prototype** `BtLibSdpGetRawDataElementType` (header)  
-> header           The first byte of a data element

**Result** The type of the data element.

**Comments** The first byte of a SDP data element contains the type and size of the data element.

The result of this macro is one of the following constants:

### **Data Element Types**

`btLibDETD_NIL` Nil, the null type

`btLibDETD_UINT` Unsigned Integer.

`btLibDETD_SINT` Signed Integer

`btLibDETD_UUID` UUID, a universally unique identifier

`btLibDETD_TEXT` Text string

`btLibDETD_BOOL` Boolean

`btLibDETD_SEQ` Data element sequence

`btLibDETD_ALT` Data element alternative

`btLibDETD_URL` URL, a uniform resource locator

These types are discussed in greater detail in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

**See Also** [BtLibSdpGetRawDataElementSize](#),  
[BtLibSdpParseRawDataElement](#),  
[BtLibSdpVerifyRawDataElement](#)

### **New** **BtLibSdpGetServerChannelByUuid**

**Purpose** Get an available RFCOMM server channel using SDP.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpGetServerChannelByUuid
(UInt16 btLibRefNum, BtLibSocketRef socket,
BtLibDeviceAddressType *remoteDeviceP,
BtLibSdpUuidType *serviceUuidList,
UInt8 uuidListLen)
```

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number for an SDP socket.
- > `remoteDeviceP`  
Device address of a remote device to query.  
This parameter must not be NULL.
- > `serviceUuidList`  
Array of UUIDs that must match those of the  
service record. This parameter must not be  
NULL.
- > `uuidListLen` Length of `serviceUuidList`. A maximum of  
12 entries is allowed.

**Result** Returns one of the following values:

`btLibErrPending`  
The server channel will be returned through a  
callback event.

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`  
Not enough memory to complete request

`btLibErrParamError`  
One or more parameters is invalid.

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

`btLibErrSocket` The specified socket is invalid or not in use.  
`btLibErrSocketRole`  
The specified socket is not connected.  
`btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function returns the RFCOMM server channel number of the first SDP record on the remote device that contains all the specified UUIDs.

This function generates a [btLibSocketEventSdpGetServerChannelBy Uuid](#) event when the query completes or fails.

**See Also** [BtLibSdpGetPSMByUuid](#)

**New**

---

## BtLibSdpParseRawDataElement

**Purpose** Parse a raw SDP data element to determine where the data field begins and the size of the data field.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpParseRawDataElement  
(UInt16 btLibRefNum, const UInt8 *dataElementP,  
UInt16 *offset, UInt32 *length)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `dataElementP`  
Pointer to a raw SDP data element.
- <- `offset` Offset, in bytes, between `dataElementP` and the start of the data field.

`<- lengthP`      Length, in bytes, of the data field.

**Result**      Returns one of the following values:

`btLibErrNoError`

Successfully parsed the attribute.

`btLibErrNotOpen`

The reference Bluetooth library is not open.

`btLibErrParamError`

`dataElementP`, `offset`, or `length` is NULL.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments**      A data element has three fields. The first field, called the *header field*, identifies the type of value stored in the data element and the size of the element. The second field, called the *size field*, contains more information about the size of the data if it's not completely specified by the header. Otherwise the size field is omitted. The third field, called the *data field*, contains the data element's actual value.

The offset this function returns is the offset between the start of the data element and the data field. The size this function returns is the size of the data field. Note that the sum of the offset and the size is the size of the data element.

This function is especially useful for iterating through entries in a list attribute.

The *Specification of the Bluetooth System* has more information about the structure of a data element.

**See Also**      [BtLibSdpVerifyRawDataElement](#),  
[BtLibSdpGetRawDataElementType](#),  
[BtLibSdpGetRawDataElementSize](#)

## **New** BtLibSdpServiceRecordCreate

**Purpose** Allocate a memory chunk that represents an SDP service record.

**Declared In** BtLib.h

**Prototype** Err BtLibSdpServiceRecordCreate  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle \*recordH)

**Parameters** -> btLibRefNum Reference number for the Bluetooth library.  
<- recordH SDP memory handle for the new SDP memory record.

**Result** Returns one of the following values:

btLibErrNoError

Success.

btLibErrNotOpen

The referenced Bluetooth library is not open.

btLibErrOutOfMemory

Not enough memory to allocate the memory chunk.

btLibErrParamError

recordH is NULL.

btLibErrStackNotOpen

The Bluetooth stack failed to initialize when the library was opened.

[BtLibSdpServiceRecordStartAdvertising,](#)  
[BtLibSdpServiceRecordStopAdvertising](#)

## **New** **BtLibSdpServiceRecordDestroy**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Free the memory associated with a SDP memory record.                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>BtLib.h</code>                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>   | <pre>Err BtLibSdpServiceRecordDestroy (UInt16 btLibRefNum, BtLibSdpRecordHandle recordH)</pre>                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p>-&gt; <code>btLibRefNum</code> Reference number for the Bluetooth library.</p> <p>-&gt; <code>recordH</code> SDP memory handle associated with the memory chunk to be freed.</p>                                                                                                                                                                                                                     |
| <b>Result</b>      | Returns one of the following values:<br><br><code>btLibErrNoError</code><br>Success.<br><br><code>btLibErrNotOpen</code><br>The referenced Bluetooth library is not open.<br><br><code>btLibErrParamError</code><br><code>recordH</code> does not refer to a valid SDP memory record.<br><br><code>btLibErrStackNotOpen</code><br>The Bluetooth stack failed to initialize when the library was opened. |
| <b>Comments</b>    | This function stops advertising the record before it frees it.                                                                                                                                                                                                                                                                                                                                          |
| <b>See Also</b>    | <a href="#">BtLibSdpServiceRecordCreate</a> ,<br><a href="#">BtLibSdpServiceRecordStartAdvertising</a> ,<br><a href="#">BtLibSdpServiceRecordStopAdvertising</a>                                                                                                                                                                                                                                        |

## **New** BtLibSdpServiceRecordGetAttribute

**Purpose** Retrieve the value of a specific attribute in a SDP memory record. If the attribute is a list or a protocol descriptor list (a list of lists), this function retrieves the value of a specific list entry.

**Declared In** BtLib.h

**Prototype**

```
Err BtLibSdpServiceRecordGetAttribute
(UInt16 btLibRefNum,
BtLibSdpRecordHandle recordH,
BtLibSdpAttributeIdType attributeID,
BtLibSdpAttributeDataType *attributeValues,
UInt16 listNumber, UInt16 listEntry)
```

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > recordH Handle identifying the SDP memory record.
- > attributeID Attribute identifier of the attribute to retrieve.
- <- attributeValues  
Buffer into which this function stores the attribute's value. You must allocate this buffer. This pointer must not be NULL.
- > listNumber List to query if the attribute is a protocol descriptor list. Otherwise this parameter is ignored.
- > listEntry Item to get in the list if the attribute is a list attribute. Otherwise this parameter is ignored.

**Result** Returns one of the following values:

btLibErrNoError  
Success.

btLibErrPending  
The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

`btLibErrBusy`

The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

`recordH` is an invalid handle or  
`attributeValues` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

#### **Comments**

If the specified SDP memory record refers to a service record on a remote device, this function generates a [btLibSocketEventSdpGetAttribute](#) event when the result is available or the query fails. In this case, the buffer to which `attributeValues` points must not be freed before the event occurs; making the buffer global ensures that it remains over the duration of the SDP query.

If you are retrieving a string or a URL, you need to allocate additional space. See the documentation for [BtLibSdpAttributeDataType](#) for more information.

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

This function supports the universal attributes defined in “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

**See Also** [BtLibSdpServiceRecordSetAttribute](#),  
[BtLibSdpServiceRecordMapRemote](#),  
[BtLibSdpServiceRecordGetNumListEntries](#),  
[BtLibSdpServiceRecordGetNumLists](#),  
[BtLibSdpServiceRecordGetStringOrUrlLength](#)

---

### **New** BtLibSdpServiceRecordGetNumListEntries

**Purpose** Get the number of entries in a list attribute.

**Declared In** BtLib.h

**Prototype** Err BtLibSdpServiceRecordGetNumListEntries  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH,  
BtLibSdpAttributeIdType attributeID,  
UInt16 listNumber, UInt16 \*numEntries)

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > recordH Handle identifying the SDP memory record.
- > attributeID Attribute identifier of the attribute whose number of list entries is retrieved.
- > listNumber List to query if the attribute is a ProfileDescriptorListEntry. Otherwise this parameter is ignored.
- <- numEntries Number of entries in the list.

**Result** Returns one of the following values:

btLibErrNoError  
Success

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

`btLibErrPending`

The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

`btLibErrBusy`

The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

Another query is pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform this query.

`btLibErrParamError`

`recordH` is an invalid handle or `numEntries` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to open when the library was opened.

**Comments** This function supports the universal attributes defined in “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*. Specifically, this function gives valid results for `ServiceClassIdList`, `ProtocolDescriptorList`, `BrowseGroupList`, `LanguageBaseAttributeIDList`, and `ProfileDescriptorList` attributes. If the specified SDP memory record refers to a service record on a remote device, this function generates a

## Bluetooth Library: Sockets and Service Discovery

[BtLibSdpServiceRecordGetStringOrUrlLength](#),  
[BtLibSdpServiceRecordMapRemote](#)

### **New** **BtLibSdpServiceRecordGetNumLists**

**Purpose** Get the number of lists in a protocol descriptor list SDP attribute.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordGetNumLists  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH,  
BtLibSdpAttributeIdType attributeID,  
UInt16 *numLists)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `recordH` Handle identifying the SDP memory record.
- > `attributeID` Attribute identifier of the attribute whose number of lists is retrieved.
- <- `numLists` Number of lists.

**Result** Returns one of the following values:

`btLibErrNoError`  
Success.

`btLibErrPending`  
The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

`btLibErrBusy`

The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrInProgress`

Another query is pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform this query.

`btLibErrParamError`

`recordH` is an invalid handle or `numLists` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to open when the library was opened.

**Comments** If the specified SDP memory record refers to a service record on a remote device, this function generates a [btLibSocketEventSdpGetNumLists](#) event when the result is available or the query fails.

**See Also** [BtLibSdpServiceRecordGetNumListEntries](#),  
[BtLibSdpServiceRecordGetAttribute](#),  
[BtLibSdpServiceRecordGetStringOrUrlLength](#),  
[BtLibSdpServiceRecordMapRemote](#)

## **New** BtLibSdpServiceRecordGetRawAttribute

**Purpose** Retrieve the value of an attribute of an SDP memory record. The retrieved attribute is in the format defined in the “Service Discovery Protocol” chapter of the *Specification of the Bluetooth System*.

**Declared In** BtLib.h

**Prototype**

```
Err BtLibSdpServiceRecordGetRawAttribute
(UInt16 btLibRefNum,
BtLibSdpRecordHandle recordH,
BtLibSdpAttributeIdType attributeID,
UInt8 *value, UInt16 *valSize)
```

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > recordH Handle identifying the SDP memory record.
- > attributeID Attribute identifier of the attribute to retrieve.
- <- value Buffer into which this function stores the retrieved SDP attribute data. You must allocate this buffer. This pointer must not be NULL.
- <-> valSize Size of the value buffer upon entry. This parameter must not be zero. Upon return, contains the number of bytes retrieved.

**Result** Returns one of the following values:

btLibErrNoError  
Success.

btLibErrPending  
The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

btLibErrBusy  
The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

`recordH` is an invalid handle, `value` is `NULL`, `valSize` is 0, or the size of the attribute value is larger than `valSize`.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the specified SDP memory record refers to a service record on a remote device, this function generates a [btLibSocketEventSdpGetRawAttribute](#) event when the result is available or the query fails.

**See Also** [BtLibSdpServiceRecordSetRawAttribute](#),  
[BtLibSdpServiceRecordGetSizeOfRaw Attribute](#),  
[BtLibSdpServiceRecordMapRemote](#)

## **New** BtLibSdpServiceRecordGetSizeOfRawAttribute

**Purpose** Return the size, in bytes, of any attribute of an SDP memory record.

**Declared In** BtLib.h

**Prototype**

```
Err BtLibSdpServiceRecordGetSizeOfRawAttribute
(UInt16 btLibRefNum,
BtLibSdpRecordHandle recordH,
BtLibSdpAttributeIdType attributeID,
UInt16 *size)
```

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > recordH Handle identifying the SDP memory record.
- > attributeID Attribute identifier of the attribute whose size is retrieved.
- <- size Pointer to a UInt16 to store the size of the attribute. This parameter must not be NULL.

**Result** Returns one of the following values:

btLibErrNoError  
Success.

btLibErrPending  
The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

btLibErrBusy  
The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

`recordH` is an invalid handle or `size` is NULL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified service record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the specified SDP memory record refers to a service record on a remote device, this function generates a [`btLibSocketEventSdpGetRawAttributeSize`](#) event when the result is available or the query fails.

**See Also** [`BtLibSdpServiceRecordGetRawAttribute`](#),  
[`BtLibSdpServiceRecordMapRemote`](#),  
[`BtLibSdpServiceRecordSetRawAttribute`](#)

## **New** BtLibSdpServiceRecordGetStringOrUrlLength

**Purpose** Get the length of a string or URL attribute in a SDP memory record.

**Declared In** BtLib.h

**Prototype**

```
Err BtLibSdpServiceRecordGetStringOrUrlLength
(UInt16 btLibRefNum,
BtLibSdpRecordHandle recordH,
BtLibSdpAttributeIdType attributeID,
UInt16 *length)
```

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > recordH Handle identifying the SDP memory record.
- > attributeID Attribute identifier of the attribute whose length is retrieved.
- <- length Pointer to a UInt16 where the length of the attribute is stored. This parameter cannot be NULL.

**Result** Returns one of the following values:

btLibErrNoError  
Success.

btLibErrPending  
The specified SDP memory record refers to a service record on a remote device. The result will be returned through a callback event.

btLibErrBusy  
The connection is parked. This error can occur only if the SDP memory record refers to a service record on a remote device.

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

`btLibErrInProgress`

A query is already pending on this socket. This error can occur only if the SDP memory record refers to a service record on a remote device.

`btLibErrNoAclLink`

An ACL link to the remote device does not exist.

`btLibErrNotOpen`

The referenced Bluetooth library is not open.

`btLibErrOutOfMemory`

Not enough memory to perform the query.

`btLibErrParamError`

The `recordH` does not refer to a valid handle, length is `NULL`, or the attribute is not a string or a URL.

`btLibErrSdpAttributeNotSet`

The specified attribute does not exist in the specified SDP record.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** Bluetooth strings do not include a null terminator.

If the SDP memory record refers to a service record on a remote device, this function generates a [`btLibSocketEventSdpGetStringLen`](#) event when the result is available or the query fails.

**See Also** [`BtLibSdpServiceRecordGetAttribute`](#),  
[`BtLibSdpServiceRecordGetNumListEntries`](#),  
[`BtLibSdpServiceRecordGetNumLists`](#),  
[`BtLibSdpServiceRecordMapRemote`](#)

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

## **New** BtLibSdpServiceRecordMapRemote

**Purpose** Configure an SDP memory record so it refers to a service record on a remote device.

**Declared In** BtLib.h

**Prototype**

```
Err BtLibSdpServiceRecordMapRemote
(UInt16 btLibRefNum, BtLibSocketRef socket,
BtLibDeviceAddressType *remoteDeviceP,
BtLibSdpRemoteServiceRecordHandle remoteHandle,
BtLibSdpRecordHandle recordH)
```

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > socket Reference number of an SDP socket.
- > remoteDeviceP  
Device to query.
- > remoteHandle  
Remote service record handle.
- > recordH SDP memory handle of an empty SDP record.

**Result** Returns one of the following values:

btLibErrNoError  
The mapping was successful.

btLibErrNotOpen  
The referenced Bluetooth library is not open.

btLibErrOutOfMemory  
Not enough memory to perform mapping.

btLibErrParamError  
recordH is invalid or refers to an invalid  
memory chunk.

btLibErrSdpMapped  
The SDP memory record is already mapped to  
a remote service record.

`btLibErrSocket` The specified socket is invalid or not in use.

`btLibErrSocketProtocol`

The specified socket is not an SDP socket.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You must create an SDP memory record using [BtLibSdpServiceRecordCreate](#) before using this function. Note that this function does not copy the contents of the remote service record to the SDP memory record in local memory.

**New**

---

## **BtLibSdpServiceRecordSetAttribute**

**Purpose** Set the value of an attribute in an SDP memory record. If the attribute is a list or a protocol descriptor list (a list of lists), this function sets the value of a specific list entry. The SDP memory record must represent a local unadvertised service record.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordSetAttribute
(UInt16 btLibRefNum,
BtLibSdpRecordHandle recordH,
BtLibSdpAttributeIdType attributeID,
BtLibSdpAttributeDataType *attributeValue,
UInt16 listNumber, UInt16 listEntry)
```

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `recordH` Handle of the service record to modify.
- > `attributeID` Attribute identifier of the attribute to set.
- > `attributeValue` Pointer to the new value for the attribute. This pointer must not be NULL.

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

- > `listNumber` List to modify if the attribute is a protocol descriptor list. Otherwise this parameter is ignored.
- > `listEntry` Item to set in the list if the attribute is a list attribute. Otherwise this parameter is ignored.

**Result** Returns one of the following values:

- `btLibErrNoError`  
Success.
- `btLibErrAdvertised`  
An advertised record was passed in `recordH`. The record must not be advertised.
- `btLibErrNotOpen`  
The referenced Bluetooth library is not open.
- `btLibErrOutOfMemory`  
Not enough memory to set the attribute.
- `btLibErrParamError`  
`recordH` is invalid or `attributeValue` is NULL.
- `btLibErrRemoteRecord`  
A remote record was passed in `recordH`. The record must be local.
- `btLibErrStackNotOpen`  
The Bluetooth stack failed to initialize when the library was opened.

**Comments** This function only works on SDP memory records that are local and not advertised. You can advertise the record after you finish modifying it.

This function supports the universal attributes defined in the *Specification of the Bluetooth System*.

**See Also** [BtLibSdpServiceRecordGetAttribute](#),  
[BtLibSdpServiceRecordStartAdvertising](#),  
[BtLibSdpServiceRecordStopAdvertising](#)

## **New** **BtLibSdpServiceRecordSetAttributesForSocket**

**Purpose** Initialize an SDP memory record so it can represent an existing L2CAP or RFCOMM listener socket as a service.

**Declared In** `BtLib.h`

**Prototype**

```
Err BtLibSdpServiceRecordSetAttributesForSocket
(UInt16 btLibRefNum, BtLibSocketRef socket,
BtLibSdpUuidType *serviceUUIDList,
UInt8 uuidListLen, const Char *serviceName,
UInt16 serviceNameLen,
BtLibSdpRecordHandle recordH)
```

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number for an RFCOMM or L2CAP socket in listening mode.
- > `serviceUUIDList`  
List of UUIDs for the service record.
- > `uuidListLen` Number of entries in `serviceUUIDList`. A maximum of 12 entries is allowed.
- > `serviceName` User-friendly name for the service in English.
- > `serviceNameLen`  
Size, in bytes, of `serviceName`.
- > `recordH` Handle of the service record to be initialized.

**Result** Returns one of the following values:

`btLibErrNoError`  
Success.

`btLibErrAdvertised`  
The record specified by `recordH` is being advertised. You must stop advertising the record before you can change it.

## Bluetooth Library: Sockets and Service Discovery

---

|                                   |                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------|
| <code>btLibErrNotOpen</code>      | The referenced Bluetooth library is not open.                                                                |
| <code>btLibErrOutOfMemory</code>  | Not enough memory to store the contents of the SDP record.                                                   |
| <code>btLibErrParamError</code>   | <code>recordH</code> is not a valid record handle.                                                           |
| <code>btLibErrRemoteRecord</code> | A remote record was passed in <code>recordH</code> . Because the service is local, the record must be local. |
| <code>btLibErrSocket</code>       | The specified socket is invalid or not in use.                                                               |
| <code>btLibErrSocketRole</code>   | The specified socket is not a listener socket.                                                               |
| <code>btLibErrStackNotOpen</code> | The Bluetooth stack failed to initialize when the library was opened.                                        |

**Comments** You must first create an SDP record using [BtLibSdpServiceRecordCreate](#). However, the record must not be advertised. In other words, don't call [BtLibSdpServiceRecordStartAdvertising](#) until after calling this function.

**See Also** [BtLibSdpServiceRecordCreate](#), [BtLibSocketListen](#)

---

### **New** **BtLibSdpServiceRecordSetRawAttribute**

**Purpose** Set the value for an attribute of a SDP memory record. This function allows you to specify the attribute as an array of bytes in the format defined in the "Service Discovery Protocol" chapter of the

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

*Specification of the Bluetooth System.* The SDP memory record must represent a local unadvertised service record.

**Declared In** BtLib.h

**Prototype** Err BtLibSdpServiceRecordSetRawAttribute  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH,  
BtLibSdpAttributeIdType attributeID,  
const UInt8 \*value, UInt16 valSize)

**Parameters**

- > btLibRefNum Reference number for the Bluetooth library.
- > recordH Handle identifying the SDP memory record.
- > attributeID Attribute identifier of the attribute to set.
- > value Array of bytes containing SDP attribute data in the format defined in the SDP protocol. This parameter must not be NULL.
- > valSize Size, in bytes, of value. This parameter must not be 0.

**Result** Returns one of the following values:

btLibErrNoError  
Success.

btLibErrAdvertised  
recordH is being advertised. The record must not be advertised.

btLibErrNotOpen  
The referenced Bluetooth library is not open.

btLibErrOutOfMemory  
Not enough memory to set the attribute.

btLibErrParamError  
recordH is invalid, value is NULL, or valSize is 0.

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

`btLibErrRemoteRecord`

`recordH` refers to a service record on a remote device. The service record must be local.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** If the service record is being advertised, you must stop advertising it before you modify it.

**See Also** [BtLibSdpServiceRecordGetRawAttribute](#),  
[BtLibSdpServiceRecordSetAttribute](#),  
[BtLibSdpServiceRecordStopAdvertising](#),  
[BtLibSdpServiceRecordStartAdvertising](#)

**New**

---

## BtLibSdpServiceRecordsGetByServiceClasses

**Purpose** Get the service record handles corresponding to the service classes advertised on a remote device.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordsGetByServiceClass  
(UInt16 btLibRefNum, BtLibSocketRef socket,  
BtLibDeviceAddressType *remoteDeviceP,  
BtLibSdpUuidType *uuidList, UInt16 uuidListLen,  
BtLibSdpRemoteServiceRecordHandle *srvRecList,  
UInt16 *numSrvRec)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `socket` Reference number of an SDP socket.
- > `remoteDevice` Remote device to query.

## Bluetooth Library: Sockets and Service Discovery

### *Service Discovery Protocol Functions*

---

- > `uuidList`      Array of UUIDs identifying the service classes. This parameter must not be `NULL`.
- > `uuidListLen`    Number of elements in the `uuidList`. You can specify a maximum of 12 UUIDs.
- <- `srvRecList`     Array of service record handles into which this function stores the results of the SDP query. You must allocate this array. This pointer must not be `NULL`.
- <-> `numSrvRec`     Number of service records allocated in `srvRecList`. This value is sent to the SDP server so it can limit the number of responses. On return, the actual number of records retrieved.

**Result**      Returns one of the following values:

- `btLibErrPending`      The results will be returned through a callback event.
- `btLibErrBusy`        The connection to the remote device is parked.
- `btLibErrInProgress`    A SDP query is already in progress on this socket.
- `btLibErrNoAclLink`     An ACL link to the remote device does not exist.
- `btLibErrNotOpen`      The referenced Bluetooth library is not open.
- `btLibErrOutOfMemory`    Not enough memory to perform the query.
- `btLibErrParamError`    One or more parameters are invalid.
- `btLibErrSocket`        The specified socket is invalid or not in use.
- `btLibErrSocketProtocol`    The specified socket is not an SDP socket.

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

---

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You need to allocate `srvRecList`, an array of [BtLibSdpRemoteServiceRecordHandles](#) large enough to accommodate all of the service record handles corresponding to the specified service classes. Specify the size of the array using the `numSrvRec` parameter.

This function generates a [btLibSocketEventSdpServiceRecordHandle](#) event when the matching service records are available or the query fails.

**New**

---

## BtLibSdpServiceRecordStartAdvertising

**Purpose** Make visible an SDP memory record representing a local SDP service record. Remote devices can access visible service records through SDP.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordStartAdvertising  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `recordH` Handle of the service record to make available to remote devices.

**Result** Returns one of the following values:

`btLibErrNoError`  
Success

`btLibErrNotOpen`  
The referenced Bluetooth library is not open.

`btLibErrParamError`

`recordH` is not a valid record handle.

`btLibErrRemoteRecord`

`recordH` refers to a remote record. The record must be local.

`btLibErrSdpAdvertised`

The service record is already accessible by remote devices.

`btLibErrStackNotOpen`

The Bluetooth stack failed to initialize when the library was opened.

**Comments** You cannot modify an SDP memory record while it is available to remote devices.

**See Also** [BtLibSdpServiceRecordStopAdvertising](#)

**New**

---

## BtLibSdpServiceRecordStopAdvertising

**Purpose** Hide an SDP memory record representing a local SDP service record. Remote devices cannot access hidden service records through SDP.

**Declared In** `BtLib.h`

**Prototype** `Err BtLibSdpServiceRecordStopAdvertising  
(UInt16 btLibRefNum,  
BtLibSdpRecordHandle recordH)`

**Parameters**

- > `btLibRefNum` Reference number for the Bluetooth library.
- > `recordH` Handle of the service record to hide.

**Result** Returns one of the following values:

## Bluetooth Library: Sockets and Service Discovery

### Service Discovery Protocol Functions

| <b>Purpose</b>     | Verify that a raw SDP data element is properly formed.                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b> | BtLib.h                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <pre>Err BtLibSdpVerifyRawDataElement (UInt16 btLibRefNum, const UInt8 *value, UInt16 valSize, UInt8 maxLevel)</pre>                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <ul style="list-style-type: none"><li>-&gt; btLibRefNum Reference number for the Bluetooth library.</li><li>-&gt; value Raw SDP attribute data.</li><li>-&gt; valSize Size of value, in bytes. The size of the data element must be less than or equal to this parameter, otherwise this function fails.</li><li>-&gt; maxLevel Maximum level of recursion over which this function verifies the data element. Must be at least one.</li></ul> |
| <b>Result</b>      | Returns one of the following values: <ul style="list-style-type: none"><li>btLibErrNoError SDP data element is properly formatted.</li><li>btLibErrError SDP data element is not properly formatted.</li><li>btLibErrNotOpen The reference Bluetooth library is not open.</li><li>btLibErrParamError value is NULL.</li><li>btLibErrStackNotOpen The Bluetooth stack failed to initialize when the library was opened.</li></ul>               |
| <b>Comments</b>    | This function checks all size descriptors in the element to ensure that the data element fits into the indicated length. In the case of                                                                                                                                                                                                                                                                                                        |

## Bluetooth Library: Sockets and Service Discovery

### *Application-Defined Functions*

---

data element sequences or alternates, this function calls itself recursively.

The `maxLevel` parameter specifies the maximum number of times this function calls itself. Limiting the recursion level prevents an infinite loop if the data is bad. `maxLevel` must be large enough to handle the complete data element. For example, to verify a simple data element such as an unsigned integer, `maxLevel` must be at least 1. To verify a data element sequence of UUIDs, `maxLevel` must be at least 2.

## Application-Defined Functions

This section describes the callback functions that handle socket events. These functions are supplied by the developer and can be named anything.

---

### **New** BtLibSocketCallback

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Signal the result of a Bluetooth socket event. When the event takes place, this callback function is called. |
| <b>Declared In</b> | <code>BtLibTypes.h</code>                                                                                    |
| <b>Prototype</b>   | <pre>void (*BtLibSocketProcPtr) (BtLibSocketEventType *sEvent, UInt32 refCon)</pre>                          |
| <b>Parameters</b>  | -> <code>sEvent</code> <a href="#">BtLibSocketEventType</a> structure containing the event parameters.       |

## Bluetooth Library: Sockets and Service Discovery

*Application-Defined Functions*

---

-> refCon      General purpose integer which you can use to hold application-specific information. When you call [BtLibSocketCreate](#) to create the socket, you can specify a value to pass to this parameter.

**Result**      Returns nothing.

**Comments**      The event and status of the event are in the sEvent structure. See [Socket Callback Events](#) for more information.  
You must specify this callback function when you create a socket. You do this by calling [BtLibSocketCreate](#).

## **Bluetooth Library: Sockets and Service Discovery**

*Application-Defined Functions*

---

# Cryptography Provider Manager

---

The Cryptography Provider Manager (CPM) is a shared library that acts as a framework for cryptographic services. These services are divided into two levels:

- At the application level, the CPM provides an API that any application can use to perform cryptographic operations.
- The operations themselves are not part of the CPM; instead, they're provided by an **algorithm provider** (or **AP**). To export its functionality to the CPM, an algorithm provider implements a set of callback functions. Third party developers can create and distribute their own APs. The Palm OS provides a default algorithm provider that's used in the absence of alternatives.

The CPM provides the glue between an application and an AP. In general, this glue is invisible: You don't need to know anything about the APs that are available to use their cryptographic services. This makes it possible for an application to use common cryptographic operations without having to be overly concerned with the exact implementation of these operations. It also relieves the algorithm providers from the duty of providing their own invocation API.

---

**NOTE:** In Palm OS 5, only the application level API is offered; the ability to create and install your own algorithm provider will be supported in a later release.

---

## The Default Provider

In Palm OS 5, there is only one algorithm provider. Implemented by RSA, it provides three cryptographic services:

## Cryptography Provider Manager

### Fundamental CPM Functions

---

- Data encryption and decryption using an RC4 symmetric key stream cipher
- Message digest creation (hashing) using the SHA-1 algorithm.
- Message verification through a combination of the two other operations.

All of the Palm OS 5 cryptography operations are provided by RSA.

One of the features of the CPM library is that the developer doesn't need to know anything about cryptography. The functions are designed such that the default settings will yield satisfying results.

## Fundamental CPM Functions

The fundamental cryptography functions are:

- [CPMLibEncrypt](#) performs a data encryption operation.
- [CPMLibDecrypt](#) performs a data decryption operation.
- [CPMLibHash](#) creates a message digest.
- [CPMLibVerify](#) verifies a message that has a signature and certificate.

These functions operate on blocks of data. For example, [CPMLibEncrypt](#) takes a block of data (and a key), encrypts it, and hands back the encrypted data all in one go.

The CPM also provides sets of functions that let you perform these operations sequentially, allowing you to (for example) initialize an encryption "stream," iteratively feed data to the encryption algorithm, and then "finalize" the stream and get the encrypted data back. These functions are (for encryption) [CPMLibEncryptInit](#), [CPMLibEncryptUpdate](#), and [CPMLibEncryptFinal](#).

## Using the Crypto-Info Structures

The cryptography operations that are currently supported by the CPM library rely on four "crypto-info" data structures:

- The [APKeyInfoStruct](#) describes a symmetric key,

- [APCipherInfoStruct](#) describes an encryption/decryption operation.
- [APHashInfoStruct](#) describes message digest creation.
- [APVerifyInfoStruct](#) describes a message verification operation.

When you perform a cryptographic operation, you'll be asked for one or more of these structures. In most cases you can pass in an "empty" structure and the function will populate it for you. However, it's important that you zero the structure first.

For example, the [CPMLibHash](#) function takes a [APHashInfoStruct](#) as an argument. To use the default hashing operations, simply allocate the structure, zero it, and pass it in:

---

```
APHashInfoType hashinfo;  
MemSet ((void *)&hashinfo, sizeof (APHashInfoType), 0);  
CPMLibHash( ..., &hashInfo, ...);
```

---

When you're done with a crypto-info structure, you must "release" it:

---

```
CPMLibReleaseHashInfo( ..., &hashInfo );
```

---

## Using the Export Functions

The cryptography structures (key, hash, cipher, verification) can be "exported," or encoded into a form that can be cached. These operations are provided by the `CPMLibExportObjectInfo` functions. Purposeful details of exporting (and importing, its functional complement) are given in the individual function descriptions, below. This little section touches on a wrinkle of usage.

When you use an export function, you're asked to supply a buffer that can accommodate the encoded data. This means that you have to know how big the encoded data will be; the export function itself tells you the size through its final (reference) argument. Thus, you have to call the export function twice: Once to get the buffer size, and then again to actually get the encoded data. This is demonstrated below:

## Cryptography Provider Manager

### CPM and AP Constants

---

```
UInt32 length=0;
UInt8 *data=NULL;
Err error;

/* For demo purposes, we're only interested in the last two
 * arguments (the buffer and the buffer length). First, we
 * set the buffer to NULL, and retrieve the length.
 */
error = CPMLibExport... (... NULL, &length);

/* At this pass, we expect the function to tell us that
 * the buffer is too small. Any other return is treated
 * as an error. Note that the <length> argument is reset to
 * to the required allocation length despite the error
 * return.
 */
if (error != cpmErrBufTooSmall)
    return ...; // or whatever

/* Allocate the buffer (for brevity, the example omits
 * the error check).
 */
data = MemPtrNew(length);

/* Call the export function again to retrieve the
 * encoded data.
 */
error = CPMLibExport... ( ... data, &length);

/* This time we want a 'clean' return. */
if (error != errNone) {
    // handle the error
}
```

---

## CPM and AP Constants

---

### AP Capability Constants

The AP capability values are bitfield constants that represent the capabilities that an AP supports. The capability constants are OR'd into the `flags` field of the [APProviderInfoStruct](#) structure.

Declared in `CPMLibCommon.h`, the constants are:

---

|                             |                                                                                                                                                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>APF_MP</code>         | Streaming operations (initialize/update/finalize) are supported (“MP” stands for “multiple part”). See <a href="#">“Fundamental CPM Functions”</a> for details. Note that all APs are expected to support block operations. |
| <code>APF_HW</code>         | The AP’s algorithms are implemented in hardware (such as a SmartCard).                                                                                                                                                      |
| <code>APF_KEYGEN</code>     | Symmetric key operations (including key info import and export) are supported.                                                                                                                                              |
| <code>APF_KEYPAIRGEN</code> | Asymmetric key operations (including key info import and export) are supported.                                                                                                                                             |
| <code>APF_KEYDERIVE</code>  | Key derivation is supported.                                                                                                                                                                                                |
| <code>APF_HASH</code>       | Hashing operations (including hash info import and export) are supported.                                                                                                                                                   |
| <code>APF_CIPHER</code>     | Message encryption and decryption operations (including cipher info import and export) are supported.                                                                                                                       |
| <code>APF_SIGN</code>       | Message signing operations (including sign info import and export) are supported.                                                                                                                                           |
| <code>APF_VERIFY</code>     | Message verification operations (including verify info import and export) are supported.                                                                                                                                    |

---

---

## Block Encryption Mode Constants

The constants listed below represent the various block encryption modes that may be supported by an AP. You can request a particular mode by setting the [APCipherInfoStruct](#).mode field before passing the structure to the [CPMLibEncrypt](#) or [CPMLibDecrypt](#) function. If you don't specify a mode, the AP will choose one for you, and reset the mode field to the chosen mode.

The `APModeEnum` data type is used to type the encryption mode constants.

```
typedef UInt32 APModeEnum;
```

Note that encryption modes apply to block operations only. Specifying a mode for a stream encryption (through [CPMLibEncryptInit](#) *et al.*) has no effect.

The constants (and the type) are declared in `CPMLibConstants.h`. The constants are:

---

|                                        |                                                         |
|----------------------------------------|---------------------------------------------------------|
| <code>apModeTypeUnspecified = 0</code> | The mode isn't specified; the AP uses its default mode. |
| <code>apModeTypeNone</code>            | The encryption mode doesn't apply.                      |
| <code>apModeTypeECB</code>             | Electronic codebook mode.                               |
| <code>apModeTypeCBC</code>             | Cipher block chaining mode.                             |
| <code>apModeTypeCBC_CTS</code>         | Cipher block chaining with cipher text stealing.        |
| <code>apModeTypeCFB</code>             | Cipher feedback mode.                                   |
| <code>apModeTypeOFB</code>             | Output feedback mode.                                   |
| <code>apModeCounter</code>             | Counter mode                                            |

---

## **New Cipher Algorithm Constants**

These constants represent the different cipher algorithms that an AP may support. The algorithm type is encoded in the `type` field of the [APKeyInfoStruct](#) structure. You can request a specific algorithm by setting the value of the `type` field before passing the structure to [CPMLibGenerateKey](#). If you don't care, leave the field zero'd (`apAlgorithmTypeUnspecified`); the function will set the field to tell you which algorithm was used.

In the [APKeyInfoStruct](#) structure, the constants are typed as `APAlgorithmEnum`:

```
typedef UInt32 APAlgorithmEnum
```

The constants (and the type) are defined in `CPMLibCommon.h`. There we see the usual "unspecified" constant:

---

|                                             |                                                      |
|---------------------------------------------|------------------------------------------------------|
| <code>apAlgorithmTypeUnspecified = 0</code> | No algorithm specified; the AP will use its default. |
|---------------------------------------------|------------------------------------------------------|

---

The rest of the constants are divided into groups, below, and listed with very little additional explanation: The constants' names are reasonably self-documenting.

### **Block Cipher Algorithms**

```
apSymmetricTypeDES  
apSymmetricTypeRC2  
apSymmetricTypeRC4  
apSymmetricTypeRC5  
apSymmetricTypeRC6,  
apSymmetricTypeDESX_XDX3 ("Strong" DES)  
apSymmetricType3DES_EDE2  
apSymmetricType3DES_EDE3  
apSymmetricTypeIDEA  
apSymmetricTypeDiamond2  
apSymmetricTypeBlowfish  
apSymmetricTypeTEA (Tiny Encryption Algorithm),  
apSymmetricTypeSAFER (Safe and Fast Encryption Routine),
```

## Cryptography Provider Manager

*CPM and AP Constants*

---

apSymmetricType3WAY

apAsymmetricTypeECDSA, apAsymmetricTypeECNR,  
apAsymmetricTypeECIES, apAsymmetricTypeECDHC,  
apAsymmetricTypeECMQVC

### Key Agreement Ciphers

apKeyAgreementTypeDH (Diffie-Hellman),  
apKeyAgreementTypeDH2 (Unified Diffie-Hellman),  
apKeyAgreementTypeMQV (Menezes-Qu-Vanstone),  
apKeyAgreementTypeLUCDIF, apKeyAgreementTypeXTRDH

---

## **Export Encoding Constants**

Constants that represent different data encoding schemes that are used to convert the crypto-info structs ([APKeyInfoStruct](#), [APHashInfoStruct](#), et al.) into a form that can be cached.

The encoding formats are used by the import and export functions, [CPMLibImportKeyInfo](#), [CPMLibExportKeyInfo](#), [CPMLibImportHashInfo](#), [CPMLibExportHashInfo](#), [CPMLibImportVerifyInfo](#), [CPMLibExportVerifyInfo](#), [CPMLibImportCipherInfo](#), and [CPMLibExportCipherInfo](#).

Declared in `CPMLibCommon.h`, the constants are:

---

|                                     |                                             |
|-------------------------------------|---------------------------------------------|
| <code>IMPORT_EXPORT_TYPE_RAW</code> | The default encoding, as defined by the AP. |
| <code>IMPORT_EXPORT_TYPE_DER</code> | ASN.1 DER encoding.                         |
| <code>IMPORT_EXPORT_TYPE_XML</code> | Standardized XML encoding.                  |

---

---

## **Hashing Algorithm Constants**

The hashing constants represent various hashing algorithms. If you want to tell the AP to use a specific algorithm in a hashing operation, you would pass one of these constants as an argument to [CPMLibHash](#) or [CPMLibHashInit](#). If you want the default, use `apHashTypeUnspecified`. The algorithm that's actually used is returned through a [APHashInfoStruct](#) structure.

# Cryptography Provider Manager

## CPM and AP Constants

---

Declared in CPMLibCommon.h, the constants are:

---

|                                        |                                                                                                                                       |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <code>apHashTypeUnspecified = 0</code> | Unspecified hash algorithm; when generating a message digest, the AP decides which algorithm to use.                                  |
| <code>apHashTypeNone</code>            | Don't hash. Use this constant if you want the AP to suppress hashing in an operation, such as verification, that normally performs it |
| <code>apHashTypeMD2</code>             | Rivest Message Digest 2 (MD2)                                                                                                         |
| <code>apHashTypeMD5</code>             | Rivest Message Digest 5 (MD5)                                                                                                         |
| <code>apHashTypeSHA1</code>            | Secure Hash Algorithm-160 (SHA-1)                                                                                                     |
| <code>apHashTypeSHA256</code>          | SHA 256-bit algorithm                                                                                                                 |
| <code>apHashTypeSHA384</code>          | SHA 384-bit algorithm                                                                                                                 |
| <code>apHashTypeSHA512</code>          | SHA 512-bit algorithm                                                                                                                 |
| <code>apHashTypeHAVAL</code>           | HAVAL one-way algorithm                                                                                                               |
| <code>apHashTypeRIPEMD160</code>       | RIPEMD 160-bit                                                                                                                        |
| <code>apHashTypeTiger</code>           | Tiger algorithm                                                                                                                       |
| <code>apHashTypePanama</code>          | PANAMA algorithm                                                                                                                      |

---

---

## Key Class Constants

A key's "class" specifies whether the key is symmetric or asymmetric and, if the latter, whether it's public or private. The key class constants represent these qualities. Key class is encoded in the `keyclass` field of the [APKeyInfoStruct](#) structure.

In the struct, the constants are typed as `APKeyClassEnum`:

```
typedef UInt32 APKeyClassEnum;
```

The constants (and the type) are defined in `CPMLibCommon.h`. The constants are:

---

|                                        |                                                |
|----------------------------------------|------------------------------------------------|
| <code>apKeyClassUnspecified = 0</code> | The key's class is unspecified.                |
| <code>apKeyClassSymmetric</code>       | This is a symmetric key.                       |
| <code>apKeyClassPublic</code>          | This is the public part of an asymmetric key.  |
| <code>apKeyClassPrivate</code>         | This is the private part of an asymmetric key. |

---

---

## Key Usage Constants

---

**NOTE:** The key usage constants are currently unused.

---

The key usage constants describe the different ways that an encryption key can be used. How a key is used is encoded in the usage field of the key's [APKeyInfoStruct](#) structure.

Note that the key usage values are mutually exclusive; you can't OR a set of key usage constants to create a "selectively talented" key. The `apKeyUsageAll` constant is the only "multi-purpose" value currently provided.

The `APKeyUsageEnum` data type is used to type the key usage constants:

```
typedef UInt32 APKeyUsageEnum;
```

The constants (and the type) are defined in `CPMLibConstants.h`. The constants are

---

|                                        |                                       |
|----------------------------------------|---------------------------------------|
| <code>apKeyUsageUnspecified = 0</code> | The key's usage is unspecified.       |
| <code>apKeyUsageAll</code>             | The key can be used in any operation. |

## Plaintext Padding Constants

The plaintext padding constants describe the different ways that plaintext is padded before it's encrypted. The padding type is encoded in the padding field of an [APCipherInfoStruct](#) structure.

The `APPaddingEnum` data type is used to type the padding constants:

```
typedef UInt32 APPaddingEnum;
```

The constants (and the type) are declared in `CPMLibCommon.h`. The constants are:

---

|                                           |                                                          |
|-------------------------------------------|----------------------------------------------------------|
| <code>apPaddingTypeUnspecified = 0</code> | The padding is unspecified; the AP will use the default  |
| <code>apPaddingTypeNone</code>            | Specifically request that padding <i>not</i> be applied. |
| <code>apPaddingTypePKCS1Type1</code>      | Public Key Cryptography Standard 1, type 1               |
| <code>apPaddingTypePKCS1Type2</code>      | Public Key Cryptography Standard 1, type 2               |
| <code>apPaddingTypePKCS5</code>           | Public Key Cryptography Standard 5                       |
| <code>apPaddingTypeOAEP</code>            | Optimal Asymmetric Encryption Padding                    |
| <code>apPaddingTypeSSLv23</code>          | Secure Sockets Layer version 23                          |

---

## CPM and AP Structures and Data Types

---

### APCipherInfoStruct

The `APCipherInfoStruct` encapsulates information about an instance of a data encryption or decryption operation. The structure is populated and returned by the data encryption and decryption functions ([CPMLibEncrypt](#), [CPMLibDecrypt](#), [CPMLibEncryptInit](#), and [CPMLibDecryptInit](#)). You can set some of the fields' values yourself (before calling an encryption/decryption function) to fine-tune the impending operation.

## Cryptography Provider Manager

### CPM and AP Structures and Data Types

---

You're responsible for allocating and freeing the `APCipherInfoStructs` that you need—the CPM never allocates them for you. The `APCipherInfoStructs` that you create (and actually use) must be released through [CPMLibReleaseCipherInfo](#) before they're freed.

For more information (including examples) on how to use a crypto-info structure, see "[Using the Crypto-Info Structures](#)."

Declared in `CPMLibCommon.h`, the structure looks like this:

```
struct APCipherInfoStruct {
    APProviderContextType providerContext;
    APAlgorithmEnum type;
    APPaddingEnum padding;
    UInt8 *iv;
    UInt32 ivLength;
    void *algorithmParams;
};
```

The fields are:

---

|                              |                                                                                                                                   |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>providerContext</code> | Information about the AP that performed (or is requested to perform) the operation. See <a href="#">APProviderContextStruct</a> . |
| <code>type</code>            | Constant that represents the cipher algorithm that was used or that's requested. See <a href="#">Cipher Algorithm Constants</a>   |
| <code>padding</code>         | Constant that represents the plaintext padding scheme used by the algorithm. See <a href="#">Plaintext Padding Constants</a> .    |
| <code>iv</code>              | Initialization vector.                                                                                                            |
| <code>ivLength</code>        | The length of the initialization vector, in bytes.                                                                                |
| <code>algorithmParams</code> | Additional data that's fed to the algorithm, as specified by the AP.                                                              |

---

## **APHashInfoStruct**

The APHashInfoStruct contains information about an instance of a message digest operation. You allocate the structure yourself, zero its contents, set the fields that you're interested in (if any), and then pass it as an argument to the message digest functions ([CPMLibHash](#), [CPMLibHashInit](#), [CPMLibExportHashInfo](#), and so on). When you're finished with the struct, you pass it to [CPMLibReleaseHashInfo](#).

For more information (including examples) on how to use the structure, see "[Using the Crypto-Info Structures](#)."

Declared in CPMLibCommon.h, the structure looks like this:

```
struct APHashInfoStruct {
    AProviderContextType  providerContext;
    APHashEnum  type;
    UInt32  length;
};
```

The fields are:

---

|                 |                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------|
| providerContext | Information about the AP that performed (or is requested to perform) the operation. See <a href="#">AProviderContextStruct</a> . |
| type            | The hashing algorithm that was used to create (or is requested to create) the message digest.                                    |
| length          | The length of the digest.                                                                                                        |

---

The APHashInfoStruct is one of the crypto-info structures; it's used as an input/output argument to the message digest functions ([CPMLibHash](#), [CPMLibHashInit](#), [CPMLibExportHashInfo](#), and so on). You allocate the structure yourself; before passing the struct to a function, you *must* zero its contents. When you're finished with the struct, you pass it to [CPMLibReleaseHashInfo](#). For more

## Cryptography Provider Manager

CPM and AP Structures and Data Types

---

information on how to use a crypto-info structure, see "[Using the Crypto-Info Structures.](#)"

**New**

---

### APKeyInfoStruct

The APKeyInfoStruct holds information about an encryption key.

```
struct APKeyInfoStruct {
    AProviderContextType providerContext;
    AAlgorithmEnum type;
    AKeyUsageEnum usage;
    AKeyClassEnum keyclass;
    UInt32 length;
    UInt32 actualLength;
    UInt16 exportable;
    UInt16 ephemeral;
};
```

|                 |                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------|
| providerID      | Algorithm provider ID number.                                                                               |
| type            | A code that identifies the type of algorithm, one of the <a href="#">Cipher Algorithm Constants</a> values. |
| usage           | A code that identifies how the algorithm is used, one of the <a href="#">Key Usage Constants</a> values.    |
| keyLength       | Length of the key data, in bytes and padded to the next largest word. (Default is 8.)                       |
| keyActualLength | The actual, unpadded length of the key data. (Default is 7.)                                                |
| exportable      | Can this key be used in a CPMSExportKey() call?. 1 if it can, 0 if it can't.                                |
| ephemeral       | Is this a "one-shot" key? 1 if it is, 0 if it's permanent..                                                 |

---

## **APPProviderContextStruct**

The APPProviderContextStruct contains information about an instance of a cryptographic operation. The structure is contained (as an APPProviderContextType value) in the four crypto-info structs, [APKeyInfoStruct](#), [APHashInfoStruct](#), [APCipherInfoStruct](#), and [APVerifyInfoStruct](#).

Declared in CPMLibCommon.h, the structure looks like this:

```
struct APPProviderContextStruct {
    UInt32  providerID;
    void  *localContext;
};
```

The fields are

---

|              |                                                                                   |
|--------------|-----------------------------------------------------------------------------------|
| providerID   | Integer that uniquely identifies the provider that's being used in the operation. |
| localContext | Provider-specific information about the operation.                                |

---

---

## **APPProviderInfoStruct**

The APPProviderInfoStruct contains information about a specific algorithm provider. The structure is returned (as an APPProviderInfoType) by [CPMLibGetProviderInfo](#).

Declared in CPMLibCommon.h, the structure looks like this:

```
struct APPProviderInfoStruct {
    char  name[32];
    char  other[64];
    UInt32  flags;
    UInt8  numAlgorithms;
    Boolean  bHardware;
};
```

# Cryptography Provider Manager

## CPM and AP Structures and Data Types

---

The fields are

---

|               |                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| name          | The human-readable name of the provider.                                                                                                                               |
| other         | Additional textual information.                                                                                                                                        |
| flags         | A bitfield that publishes the functionality that this provider supports. See <a href="#">AP Capability Constants</a> for a list of values that this field can combine. |
| numAlgorithms | A count of the algorithms this provider supplies.                                                                                                                      |
| bHardware     | true if the provider's algorithms are implemented in hardware; false if in software.                                                                                   |

---

**New**

---

## APVerifyInfoStruct

The `APVerifyInfoStruct` is used by the verification functions ([CPMLibVerify](#), *et al.*) to verify a message. It contains (primarily) the hash operation and cipher operation information that will be used during verification. It's the caller's responsibility to allocate and embed the structure's `APHashInfoStruct` and `APCipherInfoStruct` fields before passing the `APVerifyInfoStruct` to a verification function.

Any `APVerifyInfoStructs` that you actually use must be released through [CPMLibReleaseVerifyInfo](#) before it's freed. The embedded structures must also be released through [CPMLibReleaseCipherInfo](#) and [CPMLibReleaseHashInfo](#).

For more information (including examples) on how to use a crypto-info structure, see "[Using the Crypto-Info Structures](#)."

Declared in `CPMLibCommon.h`, the structure looks like this:

```
struct APVerifyInfoStruct {
    APProviderContextType providerContext;
```

```
    APHashInfoType *hashInfoP;  
    APCipherInfoType *cipherInfoP;  
}
```

The fields are:

---

|                 |                                                                                                                                   |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------|
| providerContext | Information about the AP that performed (or is requested to perform) the operation. See <a href="#">APProviderContextStruct</a> . |
| hashInfoP       | <a href="#">APHashInfoStruct</a> that contains the certificate's hash information.                                                |
| cipherInfoP     | <a href="#">APCipherInfoStruct</a> that contains the certificate's cipher information.                                            |

---

---

## CPMInfoStruct

Structure that provides information about the CPM library. It's used by the [CPMLibGetInfo](#) function.

```
typedef struct CPMInfoStruct {  
    UInt8  numInstances;  
    UInt8  numProviders;  
    Boolean defaultProviderPresent;  
};
```

The fields are:

---

|                        |                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------|
| numInstances           | The number of clients (applications) that are talking to this library.                                    |
| numProviders           | The number of algorithm providers that this library knows about.                                          |
| defaultProviderPresent | Does the library contain a default provider? <code>true</code> if it does, otherwise <code>false</code> . |

---

## CPM Functions

---

### CPMLibDecrypt

**Purpose** Decrypts a block of encrypted data.

**Declared In** CPMLib68kInterface.h, CPMLibARMInterface.h

**Prototype** Err CPMLibDecrypt ( UInt16 libRef,  
APKeyInfoType \*keyInfo,  
APCipherInfoType \*cipherInfo, UInt8 \*inBuffer,  
UInt32 inBufferLength, UInt8 \*outBuffer,  
UInt32 \*outBufferLength )

**Parameters**

- > libRef (68k only) CPM Library reference number.
- > keyInfo [APKeyInfoStruct](#) that contains the key that was used to encrypt the data. You obtain the structure by importing the [APKeyInfoStruct](#) that was exported by the data encryptor.
- <-> cipherInfo A pointer to an [APCipherInfoStruct](#) that describes the parameters that will be used in the decryption operation. You typically retrieve the structure by importing the [APCipherInfoStruct](#) that was exported by the data encryptor. If you're using the decryption defaults provided by the CPM library, you can pass in a freshly allocated (and zero'd) [APCipherInfoStruct](#); in this case, the structure will be populated by this function to reflect the actual decryption parameters.
- > inBuffer A pointer to the (encrypted) data that you want to decrypt.
- > inBufferLength Length, in bytes, of inBuffer.

`<- outBuffer` A pointer to the buffer into which the decrypted data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data.

`<-> outBufferLength` You pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the decrypted data..

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This functions performs block decryption. For stream decryption, see [CPMLibDecryptInit](#).

The `keyInfo` and `cipherInfo` must agree on the algorithm type, as specified in their respective `APAlgorithmEnum` fields.

If `outBuffer` isn't big enough, the function will fail and `outBufferLength` will return the "correct" output buffer size (i.e. large enough to accommodate the encrypted data) . When this happens, simply reallocate the output buffer and call `CPMLibDecrypt` again.

### **New** CPMLibDecryptFinal

**Purpose** Finalizes a stream decryption operation.

**Declared In** CPMLib68kInterface.h, CPMLibARMInterface.h

**Prototype**

```
Err CPMLibDecryptFinal ( UInt16 libRef,  
    AKeyInfoType *keyInfo,  
    APCipherInfoType *cipherInfo, UInt8 *inBuffer,  
    UInt32 inBufferLength, UInt8 *outBuffer,  
    UInt32 *outBufferLength)
```

**Parameters**

- > libRef CPM Library reference number (68k only).
- > keyInfo Key used to decrypt the data, as returned by [CPMLibGenerateKey](#) or [CPMLibImportKeyInfo](#).
- > cipherInfo A pointer to the [APCipherInfoStruct](#) that was returned by the stream-initializing [CPMLibDecryptInit](#) call.
- > inBuffer A pointer to the data that you want to encrypt. If you already supplied all the data through previous [CPMLibDecryptUpdate](#) calls, pass NULL.
- > inBufferLength The length of inBuffer, in bytes. If inBuffer is NULL, pass 0.
- <- outBuffer A pointer to the buffer where the decrypted inBuffer data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data.

<-> outBufferLength

You pass in the (allocated) length of outBuffer, in bytes. The function resets the argument to the amount of data that was actually copied into outBuffer. If the function returns cpmErrBufTooSmall, outBufferLength is set to the minimum buffer size that's needed to accommodate the decrypted inBuffer data..

**Result** The function returns errNone upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function (optionally) decrypts a final buffer of data and then closes the decryption stream that was initialized by [CPMLibDecryptInit](#).

Note that outBuffer contains the decrypted inBuffer data only—it doesn't contain all the data that was decrypted by this stream. It's the callers responsibility to accumulate the data that was decrypted by previous, successive [CPMLibDecryptUpdate](#) calls.

## **New** CPMLibDecryptInit

**Purpose** Initializes a stream decryption session.

**Declared In** CPMLib68kInterface.h, CPMLibARMInterface.h

**Prototype** Err CPMLibDecryptInit ( UInt16 libRef,  
APKeyInfoType \*keyInfo,  
APCipherInfoType \*cipherInfo )

**Parameters**

- > libRef CPM Library reference number (68k only).
- > keyInfo [APKeyInfoStruct](#) that contains the key that was used to encrypt the data. You obtain the structure by importing the [APKeyInfoStruct](#) that was exported by the data encryptor.

## Cryptography Provider Manager

### CPM Functions

---

`<-> cipherInfo`

A pointer to an [APCipherInfoStruct](#) that describes the parameters that will be used in the decryption operation. You typically retrieve the structure by importing the [APCipherInfoStruct](#) that was exported by the data encryptor. If you're using the decryption defaults provided by the CPM library, you can pass in a freshly allocated (and zero'd) [APCipherInfoStruct](#); in this case, the structure will be populated by this function to reflect the actual decryption parameters.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function initializes a stream decryption operation. To feed data to the operation, you call [CPMLibDecryptUpdate](#) followed by [CPMLibDecryptFinal](#). The "update" function is optional; the "final" function is mandatory. For block encryption, see [CPMLibDecrypt](#).

The `keyInfo` and `cipherInfo` must agree on the algorithm type, as specified in their respective `APAlgorithmEnum` fields.

---

## **CPMLibDecryptUpdate**

Feeds data to a stream decryption operation.

**Declared In** CPMLib68kInterface.h, CPMLibARMInterface.h

**Prototype** Err CPMLibDecryptUpdate ( UInt16 libRef,  
APKeyInfoType \*keyInfo,  
APCipherInfoType \*cipherInfo, UInt8 \*inBuffer,  
UInt32 inBufferLength, UInt8 \*outBuffer,  
UInt32 \*outBufferLength)

**Parameters** see [CPMLibEncryptFinal](#)

**Result** The function returns errNone upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds data into the stream decryption session that was started by [CPMLibDecryptInit](#). You can make any number of CPMLibDecryptUpdate calls while the stream is open. When you've finished feeding data into the stream, you call [CPMLibDecryptFinal](#).

This function's arguments, return values, and behavior are nearly identical to [CPMLibDecryptFinal](#) (which see for details). The only difference between them is that this function leaves the stream open, and [CPMLibDecryptFinal](#) closes it.

### **New** CPMLibEncrypt

**Purpose** Encrypts a block of data.

**Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h

**Prototype** Err CPMLibEncrypt ( UInt16 libRef,  
APKeyInfoType \*keyInfo,  
APCipherInfoType \*cipherInfo, UInt8 \*inBuffer,  
UInt32 inBufferLength, UInt8 \*outBuffer,  
UInt32 \*outBufferLength)

**Parameters**

- > libRef CPM Library reference number (68k only).
- > keyInfo A pointer to an [APKeyInfoStruct](#) that represents the key that will be used to encrypt the data. The allocate the structure, zero it, and then populate it by calling [CPMLibGenerateKey](#) or [CPMLibImportKeyInfo](#).
- > cipherInfo A pointer to an [APCipherInfoStruct](#) that you can use to set the parameters of the encryption operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default cipher settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation.
- > inBuffer A pointer to the data that you want to encrypt.
- > inBufferLength The length of inBuffer, in bytes.
- <- outBuffer A pointer to the buffer where the encrypted data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the encrypted data.

<-> `outBufferLength`

You pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the encrypted data.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function performs block encryption. For stream encryption, see [CPMLibEncryptInit](#).

The `keyInfo` and `cipherInfo` must agree on the algorithm type, as specified in their respective `APAlgorithmEnum` fields.

If `outBuffer` isn't big enough, the function will fail and `outBufferLength` will return the "correct" output buffer size (i.e. large enough to accommodate the encrypted data). When this happens, simply reallocate the output buffer and call `CPMLibEncrypt` again.

After you've encrypted the data, you must export the `keyInfo` and `cipherInfo` structures (see [CPMLibExportKeyInfo](#) and [CPMLibExportCipherInfo](#)) so they can be imported, later, by the data decryptor. Secure storage and transmission of the encryption key is the caller's responsibility.

To decrypt encrypted data, you call [CPMLibDecrypt](#) or [CPMLibDecryptInit](#).

### **New** CPMLibEncryptFinal

**Purpose** Finalizes a stream encryption operation.

**Declared In** CPMLib68kInterface.h, CPMLibARMInterface.h

**Prototype**

```
Err CPMLibEncryptFinal ( UInt16 libRef,  
    AKeyInfoType *keyInfo,  
    APCipherInfoType *cipherInfo, UInt8 *inBuffer,  
    UInt32 inBufferLength, UInt8 *outBuffer,  
    UInt32 *outBufferLength)
```

**Parameters**

- > libRef CPM Library reference number (68k only).
- > keyInfo Key used to encrypt the data, as returned by [CPMLibGenerateKey](#) or [CPMLibImportKeyInfo](#).
- > cipherInfo A pointer to the [APCipherInfoStruct](#) that was returned in the stream-initializing [CPMLibEncryptInit](#) call.
- > inBuffer A pointer to the data that you want to encrypt. If you already supplied all the data through previous [CPMLibEncryptUpdate](#) calls, pass NULL.
- > inBufferLength The length of inBuffer, in bytes. If inBuffer is NULL, pass 0.
- <- outBuffer A pointer to the buffer where the encrypted inBuffer data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate the encrypted inBuffer data.

<-> `outBufferLength`

You pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the encrypted data.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function (optionally) encrypts a final buffer of data and then closes the encryption stream that was initialized by [CPMLibEncryptInit](#).

After you've encrypted the data, you should export the `keyInfo` and `cipherInfo` structures (see [CPMLibExportKeyInfo](#) and [CPMLibExportCipherInfo](#)) so they can be imported, later, by the data decryptor. Secure storage and transmission of the encryption key is the caller's responsibility.

Note that `outBuffer` contains the encrypted `inBuffer` data only—it doesn't contain all the data that was encrypted by this stream. It's the callers responsibility to accumulate the data that was encrypted by previous, successive [CPMLibEncryptUpdate](#) calls.

To decrypt encrypted data, you call [CPMLibDecrypt](#) or [CPMLibDecryptInit](#).

### **New** CPMLibEncryptInit

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |           |                                          |            |                                                                                                                         |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| -> libRef          | CPM Library reference number (68k only).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |           |                                          |            |                                                                                                                         |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -> keyInfo         | Key used to encrypt the data, as returned by <a href="#">CPMLibGenerateKey</a> or <a href="#">CPMLibImportKeyInfo</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |           |                                          |            |                                                                                                                         |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| -> cipherInfo      | A pointer to an <a href="#">APCipherInfoStruct</a> that you can use to set the parameters of the encryption operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default cipher settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation. The structure is used as a cookie in the subsequent <a href="#">CPMLibEncryptUpdate</a> and/or <a href="#">CPMLibEncryptFinal</a> functions.                                                                                                                                                                                                                                                                                                        |           |                                          |            |                                                                                                                         |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Result</b>      | The function returns <code>errNone</code> upon success. For other error codes, see <a href="#">CPM Error Codes</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |           |                                          |            |                                                                                                                         |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | This function initializes a stream encryption operation. To feed data to the operation, you call <a href="#">CPMLibEncryptUpdate</a> followed by <a href="#">CPMLibEncryptFinal</a> . The "update" function is optional; the "final" function is mandatory. For block encryption, see <a href="#">CPMLibEncrypt</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |           |                                          |            |                                                                                                                         |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

The `keyInfo` and `cipherInfo` must agree on the algorithm type, as specified in their respective `APAlgorithmEnum` fields.

To decrypt encrypted data, you call [CPMLibDecrypt](#) or [CPMLibDecryptInit](#).

**New**

---

## CPMLibEncryptUpdate

**Purpose** Feeds data to a stream encryption operation.

**Declared In** `CPMLib68kInterface.h`, `CPMLibARMInterface.h`

**Prototype**

```
Err CPMLibEncryptUpdate ( UInt16 libRef,
APKeyInfoType *keyInfo,
APCipherInfoType *cipherInfo, UInt8 *inBuffer,
UInt32 inBufferLength, UInt8 *outBuffer,
UInt32 *outBufferLength)
```

**Parameters** see [CPMLibEncryptFinal](#)

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds data into the stream encryption session that was started by [CPMLibEncryptInit](#). You can make any number of `CPMLibEncryptUpdate` calls while the encryption stream is open. When you've finished feeding data into the stream, you call [CPMLibEncryptFinal](#).

This function's arguments, return values, and behavior are nearly identical to [CPMLibEncryptFinal](#) (which see for details). The only difference between them is that this function leaves the stream open, and [CPMLibEncryptFinal](#) closes it.

### **New** CPMLibExportCipherInfo

**Purpose** Encodes a cipher into a form that can be cached. To reconstitute an exported cipher, pass it to [CPMLibImportCipherInfo](#).

**Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h

**Prototype** Err CPMLibExportCipherInfo ( UInt16 libRef,  
APCipherInfoType \*cipherInfo, UInt8 encoding,  
UInt8 \*exportBuffer, UInt32 exportBufferLength )

**Parameters**

- > libRef CPM Library reference number (68k only).
- > cipherInfo Structure that represents the cipher that you want to export, as created and returned by [CPMLibGenerateKey](#), or as imported through [CPMLibImportKeyInfo](#).
- > encoding Constant that specifies the type of encoding. One of IMPORT\_EXPORT\_RAW, IMPORT\_EXPORT\_DER, or IMPORT\_EXPORT\_XML. See [Export Encoding Constants](#) for details about these formats.
- <-> exportBuffer Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to NULL if you're using the function to retrieve the size of the encoded data.
- <-> exportBufferLength You pass in the size of exportBuffer in bytes. The function returns (through this argument) the size that's required to accommodate the encoded data.

**Result** The function returns errNone upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the required exportBuffer, and then again (after allocating the buffer) to get the encoded buffer. See "[Using the Export Functions](#)" for more information and a free sample.

**New**

---

## CPMLibExportHashInfo

**Purpose** Encodes an [APHashInfoStruct](#) into a form that can be cached. To reconstitute an exported hash info, pass it to [CPMLibImportHashInfo](#).

**Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h

**Prototype** Err CPMLibExportKeyInfo ( UInt16 libRef, APHashInfoType \*hashInfo, UInt8 encoding, UInt8 \*exportBuffer, UInt32 exportBufferLength )

**Parameters**

- > libRef CPM Library reference number (68k only).
- > hashInfo Structure that you want to export.
- > encoding Constant that specifies the type of encoding. One of IMPORT\_EXPORT\_RAW, IMPORT\_EXPORT\_DER, or IMPORT\_EXPORT\_XML. See [Export Encoding Constants](#) for details about these formats.

<-> exportBuffer Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to NULL if you're using the function to retrieve the size of the encoded data (see below

## Cryptography Provider Manager

### CPM Functions

---

`<-> exportBufferLength`

You pass in the size of `exportBuffer` in bytes; the function returns (through this argument) the size that's required to accommodate the encoded data.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the export buffer, and then again (after allocating the buffer) to retrieve the encoded data. See "[Using the Export Functions](#)" for more information and a free sample.

---

### **New** CPMLibExportKeyInfo

**Purpose** Encodes a [APKeyInfoStruct](#) into a form that can be cached. To reconstitute an exported key, pass it to [CPMLibImportKeyInfo](#).

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibExportKeyInfo ( UInt16 libRef, APKeyInfoType *keyInfo, UInt8 encoding, UInt8 *exportBuffer, UInt32 exportBufferLength )`

**Parameters**

- `-> libRef` CPM Library reference number (68k only).
- `-> keyInfo` Structure that you want to export.
- `-> encoding` Constant that specifies the type of encoding. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.

<-> exportBuffer

Buffer into which the function copies the encoded data. The buffer must be allocated by the caller. Point this argument to NULL if you're using the function to retrieve the size of the encoded data (see below)

<-> exportBufferLength

You pass in the size of `exportBuffer` in bytes; the function returns (through this argument) the size that's required to accommodate the encoded data.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** You call this function twice: Once to get the size of the export buffer, and then again (after allocating the buffer) to retrieve the encoded data. See "[Using the Export Functions](#)" for more information and a free sample.

**New**

---

## CPMLibExportVerifyInfo

**Purpose** Encodes a [APVerifyInfoStruct](#) into a form that can be cached. To reconstitute an exported key, pass it to [CPMLibImportVerifyInfo](#).

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibExportKeyInfo ( UInt16 libRef, APVerifyInfoType *verifyInfo, UInt8 encoding, UInt8 *exportBuffer, UInt32 exportBufferLength )`

**Parameters**

- > `libRef` CPM Library reference number (68k only).
- > `keyInfo` Structure that you want to export.

However, you may want to supply (and cache) unique seed data today in anticipation of tomorrow's derivation functionality.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |           |                                          |             |                                                                                                                                                                                                                                                                                                                                                                   |               |                                                           |             |                                                                                                                                                                                                                                                                                                                                       |
| -> seedLength      | Length of seedData, in bytes. (Pass 0 if *seedData is 0.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |           |                                          |             |                                                                                                                                                                                                                                                                                                                                                                   |               |                                                           |             |                                                                                                                                                                                                                                                                                                                                       |
| <-> keyInfo        | A pointer to a <a href="#">APKeyInfoStruct</a> that will contain the generated key. The keyInfo structure is allocated and owned by the caller. You can specify the desired provider, key-generation scheme, and so on, by setting the APKeyInfoType fields. Or, to retrieve a default key, zero the structure before you pass it in.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |           |                                          |             |                                                                                                                                                                                                                                                                                                                                                                   |               |                                                           |             |                                                                                                                                                                                                                                                                                                                                       |
| <b>Result</b>      | The function returns <code>errNone</code> upon success. For other error codes, see <a href="#">CPM Error Codes</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                                          |             |                                                                                                                                                                                                                                                                                                                                                                   |               |                                                           |             |                                                                                                                                                                                                                                                                                                                                       |
| <b>Comments</b>    | The <a href="#">APKeyInfoStruct</a> that's populated by this function can be used in subsequent encryption, decryption, and verification operations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                                          |             |                                                                                                                                                                                                                                                                                                                                                                   |               |                                                           |             |                                                                                                                                                                                                                                                                                                                                       |

# Cryptography Provider Manager

## CPM Functions

---

When you're finished using the [APKeyInfoStruct](#), you must release it through [CPMLibReleaseKeyInfo](#).

---

### **New** CPMLibGetInfo

- Purpose** Retrieves information about the CPM library.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype**

```
Err CPMLibLibGetInfo ( UInt16 libRef,
CPMInfoType *info)
```
- Parameters**
- > libRef CPM Library reference number (68k only).
  - > info Pointer to a [CPMInfoStruct](#) that returns the information about the library. See [CPMInfoStruct](#) for a description.
- Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

---

### **New** CPMLibGetProviderInfo

- Purpose** Retrieves information about a specific provider.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype**

```
Err CPMLibGetProviderInfo ( UInt16 libRef,
UInt32 providerID,
APProviderInfoType *providerInfo)
```
- Parameters**
- > libRef CPM Library reference number (68k only).
  - > providerID ID number that identifies the provider.

`<- providerInfo`

Structure into which the function places provider information. The structure is allocated and freed by the caller. The function doesn't clear inapplicable fields on the way out.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

---

## **New** CPMLibHash

**Purpose** Hashes a block of data.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibHash ( UInt16 libRef, APHashEnum type, APHashInfoType *hashInfo, UInt8 *inBuffer, UInt32 inBufferLength, UInt8 *outBuffer, UInt32 *outBufferLength )`

**Parameters**

- > `libRef` CPM Library reference number (68k only).
- > `type` A constant that represents the hashing algorithm that will be used to create the message digest. See [Hashing Algorithm Constants](#) for a list of constants. If you want the default algorithm, use `apHashTypeUnspecified`.
- > `hashInfo` A pointer to an [APHashInfoStruct](#) that you can use to set the parameters of the hashing operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation.

## Cryptography Provider Manager

### CPM Functions

---

- > `inBuffer`      A pointer to the data that you want to hash.
- > `inBufferLength`  
The length of `inBuffer`, in bytes. If `inBuffer` is NULL, pass 0.
- <- `outBuffer`      A pointer to the buffer where the hashed `inBuffer` data will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the hashed data.
- <-> `outBufferLength`  
You pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the hashed data..

**Result**      The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments**      This function performs a block hash operation. For stream hashing, use [CPMLibHashInit](#).

---

### **New**      **CPMLibHashFinal**

**Purpose**      Finalizes a hash session and returns the hashed data.

**Declared In**      `CPMLib.h`

**Prototype**      `Err CPMLibHashFinal ( UInt16 libRef,  
APHashInfoType *hashInfo, UInt8 *inBuffer,  
UInt32 inBufferLength, UInt8 *outBuffer,  
UInt32 *outBufferLength )`

**Parameters**      -> `libRef`      CPM Library reference number (68k only).

- > `hashInfo`      A pointer to the [APHashInfoStruct](#) that was returned by [CPMLibHashInit](#).
- > `inBuffer`      A pointer to the data that you want to hash. If you already supplied all the data through previous [CPMLibHashUpdate](#) calls, pass NULL.
- > `inBufferLength`      The length of `inBuffer`, in bytes. If `inBuffer` is NULL, pass 0.
- <- `outBuffer`      A pointer to the buffer where all the data that has been hashed by this stream will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the hashed data.
- <-> `outBufferLength`      You pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the hashed data.

**Result**      The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments**      This function returns all the data that was hashed by the hash stream, and then closes the stream. It follows an initial call to [CPMLibHashInit](#) and some number of calls to [CPMLibHashUpdate](#).

---

### **New**      **CPMLibHashInit**

**Purpose**      Initiates a streaming hash operation.

## Cryptography Provider Manager

### CPM Functions

---

- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype** Err CPMLibHash ( UInt16 libRef,  
APHashInfoType \*hashInfo )
- Parameters**
- > libRef CPM Library reference number (68k only).
  - > hashInfo A pointer to an [APHashInfoStruct](#) that you can use to set the parameters of the hash operation. If the CPM can't satisfy the requirements you specify in the structure, the operation will fail. If you want to use the default settings, pass in a zero'd structure. When the function returns, the structure will be filled with information describing the operation.
- Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).
- Comments** This function initializes a streaming hash operation. To feed data to the stream, you call [CPMLibHashUpdate](#) followed by [CPMLibHashFinal](#). The "update" function is optional; the "final" function is mandatory. For a block hash, see [CPMLibHash](#).

---

### **New** CPMLibHashUpdate

- Purpose** Sends data to streaming hash operation.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype** Err CPMLibHashUpdate ( UInt16 libRef,  
APHashInfoType \*hashInfo, UInt8 \*inBuffer,  
UInt32 inBufferLength)
- Parameters**
- > libRef CPM Library reference number (68k only).

- > `hashInfo` A pointer to the [APHashInfoStruct](#) that was returned by [CPMLibHashInit](#).
- > `inBuffer` A pointer to the data that you want to hash.
- > `inBufferLength`  
The length of `inBuffer`, in bytes.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds data into the streaming hash session that was started by [CPMLibHashInit](#). You can make any number of `CPMLibHashUpdate` calls while the hash stream is open. When you've finished feeding data into the stream, you call [CPMLibHashFinal](#).

Note that this function doesn't return any hashed data. All the data that's hashed by the stream is returned through the [CPMLibHashFinal](#) call.

---

## **New** CPMLibImportCipherInfo

**Purpose** Imports a previously-exported cipher info structure so that it can be used in subsequent operations.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**

```
Err CPMLibImportCipherInfo ( UInt16 libRef,
    UInt8 encoding, UInt8 *importData,
    UInt32 importDataLength,
    APCipherInfoType *cipherInfo )
```

**Parameters** -> `libRef` CPM Library reference number (68k only).

## Cryptography Provider Manager

### CPM Functions

---

- > encoding      Constant that specifies the encoding type that was used to export the key. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.
- > importData    The encoded data.
- > importDataLength      The length of importData, in bytes.
- <- cipherInfo    [APCipherInfoStruct](#) that returns the imported key. The structure must be allocated before it's passed in.

**Result**      The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**New**

---

## CPMLibImportHashInfo

**Purpose**      Imports a previously-exported hash info structure so that it can be used in subsequent operations.

**Declared In**      `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**      `Err CPMLibImportHashInfo ( UInt16 libRef,  
                                  UInt8 encoding, UInt8 *importData,  
                                  UInt32 importDataLength,  
                                  APHashInfoType *keyInfo )`

**Parameters**      -> libRef              CPM Library reference number (68k only).

- > encoding      Constant that specifies the encoding type that was used to export the key. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.
- > importData    The encoded data.
- > importDataLength    The length of importData, in bytes.
- <- hashInfo      [APHashInfoStruct](#) that returns the imported hash info. The structure must be allocated before it's passed in.

**Result**      The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**New**

---

## CPMLibImportKeyInfo

**Purpose**      Imports a previously-exported key so that it (the key) can be used in subsequent operations.

**Declared In**    `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**    `Err CPMLibImportKeyInfo ( UInt16 libRef, UInt8 encoding, UInt8 *importData, UInt32 importDataLength, APKeyInfoType *keyInfo )`

**Parameters**

- > libRef      CPM Library reference number (68k only).
- > encoding    Constant that specifies the encoding type that was used to export the key. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.

# Cryptography Provider Manager

## CPM Functions

---

-> importData The encoded data.  
-> importDataLength  
The length of importData, in bytes.  
<- keyInfo [APKeyInfoStruct](#) that returns the imported key. The structure must be allocated before it's passed in.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

---

### **New** CPMLibImportVerifyInfo

**Purpose** Imports a previously-exported verify info structure so that it can be used in subsequent operations.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibImportVerifyInfo ( UInt16 libRef, UInt8 encoding, UInt8 *importData, UInt32 importDataLength, APVerifyInfoType *keyInfo )`

**Parameters**

- > libRef CPM Library reference number (68k only).
- > encoding Constant that specifies the encoding type that was used to export the key. One of `IMPORT_EXPORT_RAW`, `IMPORT_EXPORT_DER`, or `IMPORT_EXPORT_XML`. See [Export Encoding Constants](#) for details about these formats.
- > importData The encoded data.
- > importDataLength  
The length of importData, in bytes.

<- verifyInfo [APVerifyInfoStruct](#) that returns the imported verify info. The structure must be allocated before it's passed in.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**New**

## CPMLibReleaseCipherInfo

**Purpose** Releases a [APCipherInfoStruct](#), allowing you to free it.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibReleaseCipherInfo ( UInt16 libRef, APCipherInfoType *cipherInfo )`

**Parameters**

- > `libRef` CPM Library reference number (68k only).
- > `cipherInfo` A pointer to a [APCipherInfoStruct](#) that you want to release.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**New**

## CPMLibReleaseHashInfo

**Purpose** Releases a [APKeyInfoStruct](#), allowing you to free it.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype** `Err CPMLibReleaseHashInfo ( UInt16 libRef, APHashInfoType *hashInfo )`

**Parameters**

- > `libRef` CPM Library reference number (68k only).

## Cryptography Provider Manager

### CPM Functions

---

-> hashInfo      A pointer to a [APHashInfoStruct](#) that you want to release.

**Result**      The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

---

### **New** CPMLibReleaseKeyInfo

**Purpose**      Releases a [APKeyInfoStruct](#), allowing you to free it.

**Declared In**      CPMLib68KInterface.h, CPMLibArmInterface.h

**Prototype**      `Err CPMLibReleaseKeyInfo ( UInt16 libRef,  
APKeyInfoType *keyInfo )`

**Parameters**      -> libRef      CPM Library reference number (68k only).  
-> keyInfo      A pointer to the [APKeyInfoStruct](#) that you want to release.

**Result**      The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

---

### **New** CPMLibReleaseVerifyInfo

**Purpose**      Releases a [APVerifyInfoStruct](#), allowing you to free it.

**Declared In**      CPMLib68KInterface.h, CPMLibArmInterface.h

**Prototype**      `Err CPMLibReleaseVerifyInfo ( UInt16 libRef,  
APVerifyInfoType *verifyInfo )`

**Parameters**      -> libRef      CPM Library reference number (68k only).

-> verifyInfo A pointer to a [APVerifyInfoStruct](#) that you want to release.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

---

## **New** CPMLibVerify

**Purpose** Verifies a message.

**Declared In** `CPMLib68KInterface.h`, `CPMLibArmInterface.h`

**Prototype**

```
Err CPMLibVerify ( UInt16 libRef,  
APKeyInfoType *keyInfo,  
APVerifyInfoType *verifyInfo, UInt8 *inBuffer,  
UInt32 inBufferLength, UInt8 *outBuffer,  
UInt32 *outBufferLength, UInt8 *signature,  
UInt32 signatureLength,  
VerifyResultType *verifyResult )
```

**Parameters**

- > libRef CPM Library reference number (68k only).
- > keyInfo An [APKeyInfoStruct](#) that represents the certificate's encryption key. Extracting the key data from the certificate and constructing the [APKeyInfoStruct](#) (through [CPMLibImportKeyInfo](#)) is the caller's responsibility.

## Cryptography Provider Manager

### CPM Functions

---

- > `verifyInfo` A pointer to an [APVerifyInfoStruct](#) that specifies the hash and cipher operations that should be performed during verification. This information is embedded as [APHashInfoStruct](#) and [APCipherInfoStruct](#) structures. If you want to use the default operations, allocate and zero the embedded structures. When the function returns, the structures will be populated with information describing the operations that were used.
- > `inBuffer` A pointer to the message data.
- > `inBufferLength` The length of `inBuffer`, in bytes.
- <- `outBuffer` A pointer to the buffer where the decrypted signature will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data. If you don't care about the signature, pass `NULL`.
- <-> `outBufferLength` If `outBuffer` is `NULL`, set this to 0. Otherwise, you pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the verified data.
- > `signature` A pointer to the message's signature. Extracting the signature from the message is the caller's responsibility
- > `signatureLength` The length of the signature, in bytes.

`<- verifyResult`

An integer point that returns, by reference, the result of the verification. 0 means the message was verified; non-zero means it wasn't. The meaning of a non-zero return is defined by the algorithm provider.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function performs a block verification operation. For stream verification, use [CPMLibVerifyInit](#).  
Keep in mind that a direct return of `errNone` doesn't mean that the message has been verified. The verification status is returned by reference in `verifyResult`.

**New**

## CPMLibVerifyFinal

**Purpose** Finalizes a verify session.

**Declared In** `CPMLib.h`

**Prototype**

```
Err CPMLibVerifyFinal ( UInt16 libRef,
    APKeyInfoType *keyInfo,
    APVerifyInfoType *verifyInfo, UInt8 *inBuffer,
    UInt32 inBufferLength, UInt8 *outBuffer,
    UInt32 *outBufferLength, UInt8 *signature,
    UInt32 signatureLength,
    VerifyResultType *verifyResult )
```

**Parameters**

- > `libRef` CPM Library reference number (68k only).
- > `verifyInfo` A pointer to the [APVerifyInfoStruct](#) that was returned by [CPMLibVerifyInit](#).
- > `inBuffer` A pointer to the final buffer of message data, or NULL if there's no more data..

## Cryptography Provider Manager

### CPM Functions

---

- > `inBufferLength`  
The length of `inBuffer`, in bytes.
- <- `outBuffer` A pointer to the buffer where the decrypted signature will be copied. The buffer must be allocated by the caller, and must be big enough to accommodate all of the decrypted data. If you don't care about the signature, pass `NULL`.
- <-> `outBufferLength`  
If `outBuffer` is `NULL`, set this to 0. Otherwise, you pass in the (allocated) length of `outBuffer`, in bytes. The function resets the argument to the amount of data that was actually copied into `outBuffer`. If the function returns `cpmErrBufTooSmall`, `outBufferLength` is set to the minimum buffer size that's needed to accommodate the verified data.
- > `signature` A pointer to the message's signature. Extracting the signature from the message is the caller's responsibility
- > `signatureLength`  
The length of the signature, in bytes.
- <- `verifyResult`  
An integer point that returns, by reference, the result of the verification. 0 means the message was verified; non-zero means it wasn't. The meaning of a non-zero return is defined by the algorithm provider.

**Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).

**Comments** This function feeds a final (optional) buffer of message into a verify stream that was previously initialized by [CPMLibVerifyInit](#) and augmented through successive calls to [CPMLibVerifyUpdate](#). The entire message is then verified, the results of the verification are returned in `verifyResult`, and the stream is closed.

## **CPMLibVerifyInit**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Purpose</b>     | Initiates a streaming verify operation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | CPMLib68KInterface.h, CPMLibArmInterface.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>   | <pre>Err CPMLibVerify ( UInt16 libRef,<br/>APKeyInfoType *keyInfo,<br/>APVerifyInfoType *verifyInfo )</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p>-&gt; libRef            CPM Library reference number (68k only).</p> <p>-&gt; keyInfo           An <a href="#">APKeyInfoStruct</a> that represents the certificate's encryption key. Extracting the key data from the certificate and constructing the <a href="#">APKeyInfoStruct</a> (through <a href="#">CPMLibImportKeyInfo</a>) is the caller's responsibility.</p> <p>-&gt; verifyInfo        A pointer to an <a href="#">APVerifyInfoStruct</a> that specifies the hash and cipher operations that should be performed during verification. This information is embedded as <a href="#">APHashInfoStruct</a> and <a href="#">APCipherInfoStruct</a> structures. If you want to use the default operations, allocate and zero the embedded structures. When the function returns, the structures will be populated with information describing the operations that were used.</p> |
| <b>Result</b>      | The function returns <code>errNone</code> upon success. For other error codes, see <a href="#">CPM Error Codes</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Comments</b>    | This function initializes a streaming hash operation. To feed data to the stream, you call <a href="#">CPMLibVerifyUpdate</a> followed by <a href="#">CPMLibVerifyFinal</a> . The "update" function is optional; the "final" function is mandatory. For a block hash, see <a href="#">CPMLibVerify</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

---

## **CPMLibVerifyUpdate**

- Purpose** Sends message data to a streaming verify operation.
- Declared In** CPMLib68KInterface.h, CPMLibArmInterface.h
- Prototype**

```
Err CPMLibVerifyUpdate ( UInt16 libRef,
APKeyInfoType *keyInfo,
APVerifyInfoType *verifyInfo )
UInt8 *inBuffer, UInt32 inBufferLength)
```
- Parameters**
- > libRef CPM Library reference number (68k only).
  - > keyInfo The [APKeyInfoStruct](#) that was used in the [CPMLibVerifyInit](#) call.
  - > verifyInfo A pointer to the [APVerifyInfoStruct](#) that was returned by [CPMLibVerifyInit](#).
  - > inBuffer A pointer to the message data.
  - > inBufferLength The length of inBuffer, in bytes.
- Result** The function returns `errNone` upon success. For other error codes, see [CPM Error Codes](#).
- Comments** This function feeds message data into the verify stream that was initialized by [CPMLibVerifyInit](#). When you're finished feeding data into the stream, call [CPMLibVerifyFinal](#) to close the stream and return the verification results.

## **CPM Error Codes**

The table below lists and explains the error codes that are returned by the CPM functions.

---

|                                     |                                                                                                                                                                                                                                                                                                |
|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cpmErrAlreadyOpen</code>      | Returned by <code>CPMLibOpen()</code> to indicate that the CPM library has already been opened by your application. The open library remains open.                                                                                                                                             |
| <code>cpmErrNotOpen</code>          | All CPM functions (except <code>CPMLibOpen()</code> ) expect the CPM library to be open. This code is returned if the library isn't open. To open the library, call <code>CPMLibOpen()</code> .                                                                                                |
| <code>cpmErrStillOpen</code>        | Returned by <code>CPMLibClose()</code> if the function was unable to close the library.                                                                                                                                                                                                        |
| <code>cpmErrNoProviders</code>      | Returned by <code>CPMLibOpen()</code> if the function was unable to locate (or load) any cryptography providers. Without a cryptography provider, none of the other CPM functions will work.                                                                                                   |
| <code>cpmErrNoBaseProvider</code>   | Returned by <code>CPMLibOpen()</code> if the function was unable to locate (or load) the default cryptography provider. (Note that this means that at least one non-default provider was found. If no providers were found, the function would have returned <code>cpmErrNoProviders</code> ). |
| <code>cpmErrProviderNotFound</code> | Returned by <code>CPMLibGenerateKey()</code> , <code>CPMLibEncrypt()</code> , <code>CPMLibDecrypt()</code> and other algorithm-dependent functions if the requested provider couldn't be found.                                                                                                |
| <code>cpmErrParamErr</code>         | Returned by a number of CPM functions when an argument is invalid (a pointer that points to an unallocated structure; a structure field that isn't properly set, and so on).                                                                                                                   |
| <code>cpmErrOutOfMemory</code>      | Returned by <code>CPMLibOpen()</code> if the memory for a new library handle (and the structures it represents) couldn't be allocated                                                                                                                                                          |

## Cryptography Provider Manager

### CPM Error Codes

---

---

|                                  |                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cpmErrBufTooSmall</code>   | Returned by <code>CPMLibExportKey()</code> and <code>CPMLibExportContext()</code> functions if the storage buffer (allocated by the caller) isn't big enough to accommodate the key or context. |
| <code>cpmErrBadData</code>       | Returned by algorithm functions ( <code>CPMLibEncrypt...()</code> , <code>CPMLibDecrypt...()</code> , etc.) when the key or other required data is invalid.                                     |
| <code>cpmErrUnimplemented</code> | Returned by functions that aren't currently implemented.                                                                                                                                        |
| <code>cpmErrUnsupported</code>   | Returned by functions that aren't currently supported.                                                                                                                                          |
| <code>cpmErrNoGlobals</code>     | Returned by functions that access global CPM data—functions such as <code>CPMLibEnumerateProviders()</code> and <code>CPMLibGetProviderInfo()</code> —when that data doesn't exist.             |
| <code>cpmErrKeyExists</code>     | Returned by <code>CPMLibImportKey()</code> when the key you're trying to import already exists.                                                                                                 |
| <code>cpmErrKeyNotFound</code>   | Returned by <code>CPMLibExportKey()</code> when the key you're trying to export doesn't exist.                                                                                                  |

---

# SSL Functions

---

This chapter describes the functions that are defined in the SSL library. These functions let you create and configure an SSL context, apply the SSL protocol to an existing socket, and send SSL data to and receive data over the socket.

But before you do any of that, you have to load and open the SSL library; something like this:

---

```
Err error;
UInt16 libRef;

if ( SysLibFind( kSslDBName, &libRef ) != 0 )
{
    error = SysLibLoad(kSslLibType, kSslLibCreator, &libRef);
}
/* error checking goes here. */

error = SslLibOpen( libRef );
...
```

---

After that, you typically...

1. ...create an [SslLib](#) through [SslLibCreate](#),
2. spawn an [SslContext](#) through [SslContextCreate](#),
3. set the context's socket (see the [SslContextSet\\_Socket](#) macro),
4. “open” the context through [SslOpen](#) (this enables the SSL protocol),
5. send and receive data through [SslRead](#) and [SslWrite](#),
6. and then close everything down ([SslClose](#), [SslContextDestroy](#), [SslLibDestroy](#), and [SslLibClose](#), in that order).

You can also use the more detailed [SslSend](#) and [SslReceive](#) functions to send and receive data. If you want to perform “streaming” reads—in which partial SSL records are read as the

## SSL Functions

### SSL Attribute Functions and Macros

---

data arrives—use [SslPeek](#) and [SslConsume](#). (For more on streaming, see the [ReadStream](#) attribute).

All functions described below are defined in `SslLib.h`.

## SSL Attribute Functions and Macros

An SSL context is defined, primarily, by the values of its SSL attributes. These attributes are set and retrieved through attribute-specific macros. For example, the [SslLibSet\\_InfoCallback](#) macro sets an [SslLib](#)'s [InfoCallback](#) attribute.

The attribute macros are defined in terms of a set of eight functions listed in this chapter. These functions—[SslLibSetLong](#), [SslContextSetLong](#), [SslLibSetPtr](#), [SslContextSetPtr](#), and so on—*can* be called directly, but it's suggested that you stick with the macros. If you want to call an attribute function directly, you have to identify the attribute by passing in one of the attribute constants.

The attribute macros and constants are described in [Chapter 82](#), “[SSL Attributes and Macros](#),” on page 2181.

## A Note on the Function Names

All of the SSL library functions have “`Ssl`” as a prefix. Furthermore, the expected Palm library functions ([SslLibOpen](#), [SslLibClose](#)) have an equally expected “`SslLib`” prefix. Unfortunately, another set of functions also uses “`SslLib`” as a prefix. These functions, [SslLibCreate](#), [SslLibDestroy](#), and so on, operate on instances of the [SslLib](#) data type, which type represents a generic SSL context.

Admittedly, “`SslLib`” is bad choice for the name of this data type. As pointed out in [Chapter 81](#), “[SSL Structures and Data Types](#),” when you see the [SslLib](#) data type, you should think “generic SSL context,” not “SSL library.”

## SSL Library Functions

---

### SslClose

**Purpose** Shuts down an SSL session.

**Prototype** `Err SslClose ( UInt16 libRef, SslContext *context, UInt16 flags, UInt32 timeout )`

**Parameters**

- > `libRef` (68k only) SSL library reference number.
- > `context` The context that you want to close.
- > `flags` Options that set the session's "shutdown" attributes.
- > `timeout` Amount of time to wait for the final handshake messages from the server, in milliseconds.

**Result** `errNone` means success; for other codes, see [Chapter 83, "SSL Error Codes."](#)

**Comments** By default, an SSL shutdown involves an exchange of messages with the server. As with [SslOpen](#), if this function times out, simply call it repeatedly until you get confirmation that the session has actually been closed (i.e. until the function returns `errNone`). Unlike with [SslClose](#), you needn't clear the flags when you re-call this function.

## SSL Functions

### SSL Library Functions

---

The flags set the SSL attributes that are used during the shutdown:

| Flag                                     | Meaning                                                                                                                                                                                                                                                                       |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslCloseUseDefaultTimeout</code>   | If this flag is set, the current value of the <a href="#">IoTimeout</a> attribute is used as the function's timeout, overriding the timeout argument. If it isn't set, <a href="#">IoTimeout</a> is set to <code>timeout</code> and is used as the timeout for this function. |
| <code>sslCloseDontSendShutdown</code>    | Sets the <a href="#">DontSendShutdown</a> attribute to 1. This suppresses the shutdown messages.                                                                                                                                                                              |
| <code>sslCloseDontWaitForShutdown</code> | Sets the <a href="#">DontWaitForShutdown</a> attribute to 1. This tells the function to return after it sends a shutdown message to the server, thus ignoring the server's response.                                                                                          |

---

---

## SslConsume

**Purpose** Removes data from a context's in-coming data buffer. Use after an [SslPeek](#) only.

**Prototype** `void SslConsume ( UInt16 libRef,  
SslContext *context, Int32 availableBytes )`

**Parameters**

- > `libRef` (68k only) SSL library reference number.
- > `context` Context you want to look at.
- > `availableBytes`  
The number of bytes to remove. This should always be the value that's returned to you by [SslPeek](#)'s `availableBytes` argument.

**Comments** You call this function after calling [SslPeek](#) to remove the peeked at data.

---

## **New SslContextCreate**

**Purpose** Creates a new SSL context. The object is used to open, read, write, and close an SSL session.

**Prototype** `Err SslContextCreate ( UInt16 libRef,  
SslLib *contextTemplate, SslContext **context )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > contextTemplate  
Pointer to an [SslLib](#) object that will be used as the template for this context.
- <- context  
You pass in the address of an [SslContext](#) pointer. The function allocates a new [SslContext](#) object and points your pointer at it.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** The attributes that have been set in `contextTemplate` are copied into `context`. These attributes don't include a network socket; setting the socket is typically the first thing you do with your context object. For instructions, see [Socket](#) in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181.

After you set its socket, the context object can be used to open an SSL session; see [SslOpen](#).

When you're finished using your context object, you close the session ([SslClose](#)) and destroy the object by passing it to [SslContextDestroy](#).

  
**New**

---

## **SslContextDestroy**

**Purpose** Destroys an SSL context. You should close the object's SSL session (see [SslClose](#)) before destroying it.

**Prototype** `Err SslContextDestroy ( UInt16 libRef,  
SslContext *context)`

**Parameters** -> libRef (68k only) SSL library reference number.  
-> context The context you wish to demolish.

**Result** `errNone` means success; for other codes, see [Chapter 83](#), "[SSL Error Codes](#)."

**See Also** [SslContextCreate](#)

  
**New**

---

## **SslContextGetLong**

**Purpose** Returns the value of an integer-valued SSL attribute retrieved from a context.

**Prototype** `Int32 SslLibGetLong ( UInt16 libRef,  
SslContext *context, SslAttribute attribute )`

**Parameters** -> libRef (68k only) SSL library reference number.  
-> context The context that contains the attribute.  
-> attribute Constant that represents the attribute that you want the value of. See "[SSL Attribute Constants](#)" in [Chapter 82](#), "[SSL Attributes and Macros](#)," on page 2181 for a list of attribute constants.

**Result** The attribute's value is returned directly.

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslContextSetLong](#), [SslContextSetPtr](#), [SslContextGetPtr](#)

---

## **New** **SslContextGetPtr**

**Purpose** Returns a pointer to an attribute that’s owned by a context template.

**Prototype** `Err SslLibGetPtr ( UInt16 libRef,  
SslContext *context, SslAttribute attribute,  
void **value )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context The context that contains the attribute.
- > attribute Constant that represents the attribute that you want the value of. “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181 for a list of attribute constants.
- > value You pass in the address of a pointer; the function will point your pointer to the attribute’s data. The data’s type depends on the attribute. You mustn’t free or modify the pointed to data.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

  
**New**

---

## **SslContextSetLong**

**Purpose**      Modifies a context by changing the value of one of its integer-valued SSL attributes.

**Prototype**    `Err SslLibSetLong ( UInt16 libRef,  
                      SslContext *context, SslAttribute attribute,  
                      Int32 value )`

**Parameters**

- > libRef            (68k only) SSL library reference number.
- > context            The context template you want to modify.
- > attribute        Constant that represents the attribute that you want to change. See "[SSL Attribute Constants](#)" in [Chapter 82, "SSL Attributes and Macros](#)," on page 2181 for a list of attribute constants.
- > value             The attribute's new (desired) value.

**Result**        `errNone` means success; for other codes, see [Chapter 83, "SSL Error Codes](#)."

**Comments**    You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in "[SSL Attribute Functions and Macros](#)" near the beginning of this chapter.

**See Also**     [Chapter 82, "SSL Attributes and Macros](#)," on page 2181, [SslContextSetPtr](#), [SslContextGetLong](#), [SslContextGetPtr](#)

---

## **New** SslContextSetPtr

**Purpose** Modifies a context template by changing the value of one of its pointer-valued SSL attributes.

**Prototype** `Err SslLibSetPtr ( UInt16 libRef,  
SslContext *context, SslAttribute attribute,  
void *value )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context The context you want to modify.
- > attribute Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181 for a list of attribute constants.
- > value A pointer to the attribute’s new (desired) value. The type of data that the pointer should point to is defined by the attribute.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslContextSetLong](#), [SslContextGetLong](#), [SslContextGetPtr](#)

---

## SslFlush

- Purpose** Flushes a context's out-going data buffer, sending the data to the network.
- Prototype** `Err SslFlush ( Int16 libRef, SslContext *context, Int32 *outstanding )`
- Parameters**
- > libRef (68k only) SSL library reference number.
  - > context Context you want to flush.
  - <- outstanding The number of bytes of data left in the buffer.
- Result** `errNone` means success; for other codes, see [Chapter 83, "SSL Error Codes."](#)
- Comments** If the context is in autoflush mode (the [AutoFlush](#) attribute is 0), [SslWrite](#) and [SslSend](#) calls will write their data into the context's out-going data buffer, but the data won't actually be sent to the network. To "flush" this data, you have to explicitly call `SslFlush`.  
By not autoflushing, you can make multiple, small [SslWrite](#)/[SslSend](#) followed by an `SslFlush` and thereby improve network efficiency. Although the out-going buffer size is set to the value of the [WbufSize](#) attribute, the actual number of bytes that can be written by your application is somewhat smaller due to SSL overhead. After performing a write, you should check the value of the [WriteBufPending](#) attribute; if it's approaching the [WbufSize](#) value, you should call `SslFlush`.  
When the function returns, the `outstanding` value tells how many bytes of data are left in the buffer. If this value is non-zero, the next [SslWrite](#), [SslSend](#), or `SslFlush` call will attempt to write those bytes to the network.

  
**New**

---

## SslLibClose

- Purpose** Closes a reference to the SSL library.
- Prototype** `Err SslLibClose ( UInt16 refNum )`
- Parameters** `-> refNum` SSL library reference number (68k only).
- Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)
- Comments** You can only a library that you’ve already opened. To open the SSL library, call [SslLibOpen](#).

  
**New**

---

## SslLibCreate

- Purpose** Allocates and returns new [SslLib](#) object. The object is a template that describes a generic SSL context, and is used to create “real” context objects ([SslContext](#)).
- Declared In** `SslLib.h`
- Prototype** `Err SslLibCreate ( UInt16 libRef,  
SslLib **contextTemplate )`
- Parameters** `-> libRef` (68k only) SSL library reference number.  
`<- contextTemplate`  
You pass in the address of an [SslLib](#) pointer. The function allocates an [SslLib](#) object for you, and points your pointer at it.
- Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

## SSL Functions

### SSL Library Functions

---

**Comments** You modify the context template (i.e the [SslLib](#) object) by calling the SSL attribute macros described in [Chapter 82, “SSL Attributes and Macros.”](#) You then use it as a template with which you create [SslContext](#) objects (see [SslContextCreate](#)). The latter objects are needed for actual SSL data transaction operations.

The `contextTemplate` that’s returned by this function should ultimately be destroyed through [SslLibDestroy](#).

For more on [SslLib](#), [SslContext](#), and the relationship between them, see their descriptions in [Chapter 81, “SSL Structures and Data Types,”](#) on page 2163.

---

### **New** SslLibDestroy

**Purpose** Destroys an [SslLib](#) object and frees all the memory it allocated.

**Prototype** `void SslLibDestroy ( UInt16 libRef,  
SslLib *contextTemplate )`

**Parameters** `-> libRef` (68k only) SSL library reference number.  
`-> contextTemplate`  
The [SslLib](#) you want to destroy, as previously returned by [SslLibCreate](#).

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** The [SslContext](#) objects that were spawned by this [SslLib](#) maintain a reference to their spawner. Because of this, you shouldn’t destroy an [SslLib](#) until you’ve destroyed all of its contexts.

  
**New**

---

## **SslLibOpen**

**Purpose** Opens a reference to the SSL library.

**Prototype** `Err SslLibOpen ( UInt16 libRef )`

**Parameters** -> libRef (68k only) SSL library reference number.

**Result** `errNone` means success; for other codes, see [Chapter 83, "SSL Error Codes."](#)

**Comments** When you're done using the SSL library, you must close it through [SslLibClose](#)

  
**New**

---

## **SslLibGetLong**

**Purpose** Returns the value of an integer-valued SSL attribute retrieved from a context template.

**Prototype** `Int32 SslLibGetLong ( UInt16 libRef, SslLib *contextTemplate, SslAttribute attribute )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > contextTemplate The context template that contains the attribute.
- > attribute Constant that represents the attribute that you want the value of. See "[SSL Attribute Constants](#)" in [Chapter 82, "SSL Attributes and Macros,"](#) on page 2181 for a list of attribute constants.

**Result** The attribute's value is returned directly.

## SSL Functions

### SSL Library Functions

---

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslLibSetLong](#), [SslLibSetPtr](#), [SslLibGetPtr](#)

---

### **New** SslLibGetPtr

**Purpose** Returns a pointer to an attribute that’s owned by a context template.

**Prototype**

```
Err SslLibGetPtr ( UInt16 libRef,
SslLib *contextTemplate, SslAttribute attribute,
void **value )
```

**Parameters**

- > libRef (68k only) SSL library reference number.
- > contextTemplate The context template that contains the attribute.
- > attribute Constant that represents the attribute that you want the value of. “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181 for a list of attribute constants.
- > value You pass in the address of a pointer; the function will point your pointer to the attribute’s data. The data’s type depends on the attribute. You mustn’t free or modify the pointed to data.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslLibSetLong](#), [SslLibGetLong](#), [SslLibSetPtr](#)

---

## **New** SslLibSetLong

**Purpose** Modifies a context template by changing the value of one of its integer-valued SSL attributes.

**Prototype** `Err SslLibSetLong ( UInt16 libRef,  
SslLib *contextTemplate, SslAttribute attribute,  
Int32 value )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > contextTemplate The context template you want to modify.
- > attribute Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181 for a list of attribute constants.
- > value The attribute’s new (desired) value.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslLibSetPtr](#), [SslLibGetLong](#), [SslLibGetPtr](#)

---

**New** **SslLibSetPtr**

**Purpose** Modifies a context template by changing the value of one of its pointer-valued SSL attributes.

**Prototype** `Err SslLibSetPtr ( UInt16 libRef,  
SslLib *contextTemplate, SslAttribute attribute,  
void *value )`

**Parameters**

- > `libRef` (68k only) SSL library reference number.
- > `contextTemplate` The context template you want to modify.
- > `attribute` Constant that represents the attribute that you want to change. See “[SSL Attribute Constants](#)” in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181 for a list of attribute constants.
- > `value` A pointer to the attribute’s new (desired) value. The type of data that the pointer should point to is defined by the attribute.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslLibSetLong](#), [SslLibGetLong](#), [SslLibGetPtr](#)

**Comments** You should rarely need to invoke this function directly. Instead, use the attribute macros, as described in “[SSL Attribute Functions and Macros](#)” near the beginning of this chapter.

**See Also** [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181, [SslContextGetLong](#), [SslContextSetLong](#), [SslContextSetPtr](#)

---

## **New** SslOpen

**Purpose** Opens an SSL session, possibly as a continuation of a previous session.

**Prototype** `Err SslOpen ( UInt16 libRef, SslContext *context, UInt16 flags, UInt32 timeout )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context The context object that will configure and own the session.
- > flags Options that set various SSL attributes. The most important flags are `sslOpenModeSsl` and `sslOpenModeClear`. These mutually exclusive flags tell the session to use SSL or cleartext, respectively.
- > timeout Amount of time to wait for the handshake confirmation before giving up, in milliseconds.

**Result** `errNone` means success; for other codes, see [Chapter 83, “SSL Error Codes.”](#)

**Comments** Calling `SslOpen` is essentially the same as setting the attributes that correspond to the function’s flags:

## SSL Functions

### SSL Library Functions

---

| Flag                                  | Meaning                                                                                                                                                                                                                                                                                    |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslOpenModeClear</code>         | Sets the context's <a href="#">Mode</a> attribute to <code>sslModeClear</code> (cleartext).                                                                                                                                                                                                |
| <code>sslOpenModeSsl</code>           | Sets the context's <a href="#">Mode</a> attribute to <code>sslModeSslClient</code> (SSL is enabled). This overrides <code>sslOpenModeClear</code> .                                                                                                                                        |
| <code>sslOpenNoAutoFlush</code>       | Sets the <a href="#">AutoFlush</a> attribute to 0. This suppresses auto-flushing so that <a href="#">SslWrite</a> / <a href="#">SslSend</a> data is cached until you call <a href="#">SslFlush</a> .                                                                                       |
| <code>sslOpenNewConnection</code>     | Sets the context's <a href="#">SslSession</a> attribute to NULL. This will force a full SSL handshake. If you don't set this flag, the previous <a href="#">SslSession</a> will be used (if possible), and the handshake is truncated.                                                     |
| <code>sslOpenBufferedReuse</code>     | Sets the <a href="#">BufferedReuse</a> attribute to 1. This provides an even greater savings during a (truncated) handshake.                                                                                                                                                               |
| <code>sslOpenUseDefaultTimeout</code> | If this flag is set, the current value of the <a href="#">IoTimeout</a> attribute is used as the function's timeout, overriding the <code>timeout</code> argument. If it isn't set, <a href="#">IoTimeout</a> is set to <code>timeout</code> and is used as the timeout for this function. |
| <code>sslOpenDelayHandshake</code>    | Instead of sending the final handshake message, cache it until the write buffer is flushed (through an autoflush, or through an <a href="#">SslFlush</a> call). There is no attribute that corresponds to this flag.                                                                       |

If the function times out, you should simply call it again—timing out isn't a fatal error. Each time you call `SslOpen` (after a timeout), the handshake continues from where it timed out. However, it's important that when you re-call `SslOpen`, that you clear the `flags` argument. The attributes that they affect will already have been set; setting them a second time could cause the context to be reset, which will cause the handshake to start from the beginning.

---

## SslPeek

**Purpose** Lets you look at in-coming data without actually “consuming” it.

**Prototype** `Err SslPeek ( UInt16 libRef, SslContext *context, void **data, Int32 *availableBytes, Int32 maxAvailable)`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context Context you want to look at.
- <- data Pass in the address of a pointer; the function sets your pointer to point to the context’s in-coming data buffer.
- <- availableBytes The function returns the smaller of **a)** the number of bytes of data that are waiting to be read or **b)** the value of maxAvailable.
- > maxAvailable Sets a limit on the availableBytes value.

**Result** Always returns 0.

**Comments** This function is similar to [SslRead](#), but rather than copy data into your buffer, it gives you direct access to the context’s in-coming data buffer. If the buffer is empty, data is read from the network until there are bytes available. After each successful `SslPeek` call, you should call [SslConsume](#) to clear the “peeked at” data. If you don’t consume after a peek, the next `SslPeek` will return a pointer to the same data.

`SslPeek` is meant to be used in contexts that have the [ReadStreaming](#) attribute set.

---

## **SslRead**

**Purpose** Copies a buffer of in-coming data.

**Prototype** `Int16 SslRead ( UInt16 libRef,  
SslContext *context, void *buffer,  
UInt16 bufferLength, Err *error )`

**Parameters**

- > `libRef` (68k only) SSL library reference number.
- > `context` Context that owns the session.
- <- `buffer` This is where the retrieved data will be copied. The buffer must be allocated by the caller.
- > `bufferLength` The length of `buffer`, in bytes.
- <- `error` Error code as listed in see [Chapter 83, "SSL Error Codes."](#)

**Result** Returns the number of bytes that were actually read. A return of 0 means the socket was shut down by the server. If the return is -1, look in `error` for the precise error code.

**Comments** This is a convenient cover for [SslReceive](#). It ignores the address of the sender, doesn't set any socket flags, and uses the context's current timeout setting (the [IoTimeout](#) attribute).

---

## **SslReceive**

**Purpose** Copies a buffer of in-coming data.

**Prototype** `Int16 SslReceive ( UInt16 libRef,  
SslContext *context, void *buffer,  
UInt16 bufferLength, UInt16 flags,  
void *fromAddress, UInt16 *fromAddressLength,  
Int32 timeout, Err *error )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context Context that owns the session.
- <- buffer This is where the retrieved data will be placed.
- > bufferLength  
The length of buffer, in bytes.
- > flags Options that are applied to (and stored by) the socket. See [I/O Flags](#) in [Chapter 61, "Net Library,"](#) on page 1413 for a description of these options.
- <- fromAddress  
Optionally returns the address of the sender. The fromAddress buffer must be allocated by the caller. If you don't want to retrieve the address, pass a NULL pointer.
- <-> fromAddressLength  
On input, you set \*fromAddressLength to the size of the fromAddress buffer, in bytes. Upon return, \*fromAddressLength is set to the actual size of the buffer. If you don't want to retrieve the address, pass a NULL pointer.
- > timeout Maximum timeout in system ticks; -1 means wait forever.

## SSL Functions

### SSL Library Functions

---

-> error            Error code as listed in see [Chapter 83, "SSL Error Codes."](#)

**Result**        Returns the number of bytes that were actually read. A return of 0 means the socket was shut down by the server. If the return is -1, look in `error` for the precise error code.

**Comments**     Unlike in `SslSend`, the address that you supply (`fromAddress`) doesn't overwrite the socket's address. This is a cover for the Network library's [NetLibDmReceive](#) function.

For a shorthand version of this function, see [SslRead](#).

---

## **New**        **SslSend**

**Purpose**        Writes a buffer of data to the network, or buffers it for a later send.

**Prototype**    `Int16 SslSend ( UInt16 libRef,  
SslContext *context, void *buffer,  
UInt16 bufferLength, UInt16 flags,  
void *toAddress, UInt16 toAddressLength,  
Int32 timeout, Err *error )`

**Parameters**   -> `libRef`            (68k only) SSL library reference number.  
                  -> `context`          Context that owns the SSL session.  
                  -> `buffer`            A pointer to the data that you want to write.  
                  -> `bufferLength`      The amount of data you want to write, in bytes.  
                  -> `flags`            Options that are applied to (and stored by) the socket. See [I/O Flags](#) in [Chapter 61, "Net Library,"](#) on page 1413 for a description of these options.  
                  -> `toAddress`        Address of the recipient. If this is a [NetSocketAddrType](#), the socket's address is set to this value. If it's 0, the socket's current address is used.

- > toAddressLength      Size of \*toAddress, in bytes.
- > timeout              Maximum timeout in system ticks; -1 means wait forever.
- <- error                Error code as listed in see [Chapter 83, "SSL Error Codes."](#)

**Result**      Returns the number of bytes that were actually sent. A return of 0 means the socket was shut down by the server. If the return is -1, look in error for the precise error code.

**Comments**      If the context has the [AutoFlush](#) attribute enabled, the data is immediately written to the network; otherwise, it's cached until [SslFlush](#) is called. This function is a cover for the Network library's [NetLibSend](#) function.  
For a shorthand version of this function, see [SslWrite](#).

  
**New**

---

## **SslWrite**

**Purpose**      Writes a buffer of data to the network, or caches it in anticipation of a flush.

**Prototype**      `Int16 SslWrite ( UInt16 libRef,  
SslContext *context, void *buffer,  
UInt16 bufferLength, Err *error )`

**Parameters**

- > libRef              (68k only) SSL library reference number.
- > context             Context that owns the session.
- > buffer              A pointer to the data that you want to write.
- > bufferLength        The amount of data you want to write, in bytes.

## SSL Functions

### Application-Defined Functions

---

`<- error`      Error code as listed in see [Chapter 83, “SSL Error Codes.”](#)

**Result**      Returns the number of bytes that were actually sent. A return of 0 means the socket was shut down by the server. If the return is -1, look in `error` for the precise error code.

**Comments**      This is a convenient cover for [`SslSend`](#). It doesn't set any socket flags, uses the socket's current address, and uses the context's current timeout setting (the [`IoTimeout`](#) attribute).

## Application-Defined Functions

### **New** `SslCallbackFunc`

---

**Purpose**      Prototype for SSL information and verification callback functions.

**Prototype**

```
typedef Int32
(*SslCallbackFunc) (SslCallback *callbackStruct,
Int32 command, Int32 flavor, void *info);
```

**Parameters**      `-> callbackStruct`      A structure that contains information about this callback function, including application-defined data that can be used in the function's implementation. See [`SslCallback`](#) in [Chapter 81, “SSL Structures and Data Types,”](#) on page 2163.

`-> command`      A constant that represents the general reason for the function's invocation.

`-> flavor`      A constant that refines the `command` value.

-> info                    Additional data that may be needed by the callback. The type of data that's passed depends on the command/flavor values.

**Result**     The function should return `errNone` (0) upon success, otherwise, it should return one of the error codes described in [Chapter 83, "SSL Error Codes."](#) A non-zero return value here is returned to the SSL function that caused the callback to be invoked.

**Comments**     For every context, you can install two callback functions: An "info" callback and a "verify" callback:

- The info callback is typically used for debugging, displaying data, tracking progress, and so on. It's invoked at well-defined junctures as the context is working.
- The verify callback is called when a certificate is being verified. It's expected to handle error situations.

To install a callback, you create an [SslCallback](#) structure, populate the necessary fields, and then use it to set the value of the [InfoCallback](#) or [VerifyCallback](#) attribute. When you set the info callback, you also have to set the [InfoInterest](#) attribute to register for specific events (which will show up in the flavor argument when your callback is invoked). The verify callback doesn't require similar event registration.

Setting the info callback in an [SslContext](#) looks a little bit like this:

---

```
/* Create an SslCallback structure, and point its
 * 'callback' field to your function ('MyInfoCallbackFunc').
 */
SslCallback infoCallback;
infoCallback.callback = MyInfoCallbackFunc;

/* Set the InfoCallback attribute. */
SslContextSet_InfoCallback( sslContext, &infoCallback );

/* Set the events you're interested in hearing about. */
SslContextSet_InfoInterest( sslContext,
    sslFlgInfoAlert | sslFlgInfoHandshake | sslFlgInfoIo);
```

---

When you set the [InfoCallback](#) or [VerifyCallback](#) attribute, the [SslCallback](#) structure is copied into the object. Furthermore,

## SSL Functions

### Application-Defined Functions

---

when you spawn an [SslContext](#) from an [SslLib](#), the callback structures are copied into the new object.

#### Commands and Flavors

Taken together, the `command` and `flavor` arguments tell a callback why it's being called. There are three command groups:

- The common command values (`sslCmdNew`, `sslResetNew`, and `sslCmdFree`) apply to both info and verify callbacks. These commands don't use `flavor` arguments.
- `sslCmdInfo` is used for info callbacks only. The `flavor` argument indicates the reason for the callback.
- Similarly, `sslCmdVerify` is used for verify callbacks only (and `flavor` refines the command's meaning).

#### Common Commands

The common commands are:

| Command                  | Meaning                                                                                                                                                                                                                                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslCmdNew</code>   | The callback function was just copied into an object. (More accurately, the <a href="#">SslCallback</a> that contains the function was copied.) This happens when you set the <a href="#">InfoCallback</a> or <a href="#">VerifyCallback</a> attribute, or when you spawn an <a href="#">SslContext</a> . |
| <code>sslCmdReset</code> | The context that contains this callback was just reset ( <a href="#">SslContext</a> only; see the <a href="#">Mode</a> attribute for a brief explanation of the SSL reset).                                                                                                                               |
| <code>sslCmdFree</code>  | The <a href="#">SslCallback</a> structure is about to be freed. This usually means that the <a href="#">SslLib</a> or <a href="#">SslContext</a> that owns the structure is being destroyed.                                                                                                              |

When a callback function is invoked with one of these common commands, the `flavor` argument is 0 (i.e. undefined) and `info` is NULL.

### ***sslCmdInfo Flavors***

As mentioned above, the `sslCmdInfo` command argument is only sent to the info callback (keep in mind, however, that the info callback may also receive any of the common commands).

The `flavor` values that are associated with the `sslCmdInfo` command are:

| <b>Flavor</b>                                                                                                                                    | <b>Meaning</b>                                                                                                                                                                                             |
|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslArgInfoHandshake</code>                                                                                                                 | Notification of an SSL state change. Read the <a href="#">HsState</a> attribute to determine the new state.<br><br>The callback's <code>info</code> parameter is set to NULL.                              |
| <code>sslArgInfoAlert</code>                                                                                                                     | Notification of an SSL alert. Your callback can read the <a href="#">LastAlert</a> attribute to determine which alert was received.<br><br>The callback's <code>info</code> parameter is set to NULL.      |
| <code>sslArgInfoReadBefore</code><br><code>sslArgInfoReadAfter</code><br><code>sslArgInfoWriteBefore</code><br><code>sslArgInfoWriteAfter</code> | Notifications that are sent just before and just after data is read from or written to the network.<br><br>The <code>info</code> argument is an <a href="#">SslIoBuf</a> structure that contains the data. |
| <code>sslArgCert</code>                                                                                                                          | Notification that the server's certificate chain has been verified.<br><br>The <code>info</code> argument is an <a href="#">SslExtendedItems</a> structure that contains the server's certificate.         |

### ***sslCmdVerify Flavors***

The verify callback function is called with the `sslCmdVerify` command when an error occurs during certificate verification, and

## SSL Functions

### *Application-Defined Functions*

---

when the certificate is successfully verified. The associated flavor values are:

| <b>Flavor</b>                                     | <b>Meaning</b>                                                                                              |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <code>sslErrVerifyBadSignature</code>             | The certificate's signature is invalid                                                                      |
| <code>sslErrVerifyNoTrustedRoot</code>            | A trusted certificate store (necessary for certificate verification) couldn't be found                      |
| <code>sslErrVerifyNotAfter</code>                 | The certificate has expired.                                                                                |
| <code>sslErrVerifyNotBefore</code>                | The certificate is too early (the timestamp window is in the future).                                       |
| <code>sslErrVerifyConstraintViolation</code>      | The certificate violates an X509 extension                                                                  |
| <code>sslErrVerifyUnknownCriticalExtension</code> | An X509 extension (that's marked as "critical") isn't understood by the certificate verification routines.y |
| <code>sslErrOk</code>                             | The certificate was successfully verified.                                                                  |

Note that these constants are also used as error codes. If your verify function can't fix the problem, it should return the command argument as an error.

In all cases, the `info` argument is an [SslVerify](#) structure that contains information about the certificate that's being verified.

# SSL Structures and Data Types

---

This chapter describes the structures and data types that are used by SSL.

All elements described below are defined in `SslLib.h`.

## SSL Data Types

**New**

---

### SslAttribute

The `SslAttribute` data type is used to cast the SSL attribute constants that are passed to the attribute-setting functions.

```
typedef UInt32 SslAttribute;
```

In general, you should use the attribute-setting macros rather than the functions. The attribute upon which a macro operates is embedded in its name, so you rarely have to deal with `SslAttribute` types.

For more information on the relationship between the attribute-setting functions and macros, see [Chapter 80, “SSL Functions,”](#) on page 2135. For a list of the macros themselves, go to [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181.

**New**

---

### SslContext

`SslContext` is the data type for a private structure that holds all the information, or *context*, associated with the SSL protocol that will be used in an SSL session. It contains flags that govern how the

## SSL Structures and Data Types

### SSL Data Types

---

SSL protocol will operate, read and write buffers where SSL packets are assembled and disassembled, various structures that are created as part of the SSL handshake, and so on.

The data type is declared in `SslLib.h` as:

```
typedef struct SslContext_st SslContext;
```

The lifetime of an `SslContext` follows this pattern:

1. **Creation.** You never allocate your own `SslContext` objects; instead, you first create an [SslLib](#) (which see) and pass it to the [SslContextCreate](#) function. The [SslLib](#) acts as a template that's used by the function to create and configure a new `SslContext`. This "configuration" consists of copying the [SslLib](#)'s **SSL attributes** into the new `SslContext`.
2. **Configuration.** After you get your hands on the new `SslContext`, you can refine its SSL attributes by calling the SSL attribute macros.
3. **Socket specification.** The one essential attribute that you must set is the context's socket. The template doesn't contain a reference to a socket, so if you want to actually use the `SslContext` object's that you create, you have to explicitly set its socket. See [Socket](#) in [Chapter 82, "SSL Attributes and Macros."](#)
4. **SSL sessions.** You then pass the `SslContext` to [SslOpen](#), which creates a new SSL session. The `SslContext` is used as a cookie in session operations such as [SslRead](#) and [SslClose](#). When you're done with the session, you call [SslClose](#). The same `SslContext` can be reused in successive sessions, but only one at a time.
5. **Destruction.** When you're done using the SSL context, you hand the object back to the system through [SslContextDestroy](#).

**New**

---

### SslLib

`SslLib` is the data type for a private structure that describes a generic SSL context. It's declared in `SslLib.h` as:

```
typedef struct SslLib_st  SslLib;
```

---

**NOTE:** `SslLib` is a misleading name for this data type. The type *doesn't* represent the SSL library, nor does it serve any explicit library-related function. Where you see “`SslLib`” you should think “generic SSL context.”

---

After you create and modify an `SslLib` object, you use it as a template to create “real” SSL context objects (type [SslContext](#)). When you're done with the `SslLib`, you ask the SSL library to destroy it.

Functionally, the lifetime of an `SslLib` follows this pattern:

1. **Creation.** You create the object through [SslLibCreate](#).
2. **Modification.** Since the structure that the `SslLib` represents is private, you can't touch its fields directly. Instead, you use a set of macros (defined in `SslLibMac.h`) to fine-tune the object. These macros set the values of the **SSL attributes** that the `SslLib` contains. The SSL attributes and the macros that you use to set and get their values are described in [Chapter 82, “SSL Attributes and Macros,”](#) on page 2181.
3. **Context creation.** When you're satisfied with your `SslLib`'s attribute configuration, you use it to create new [SslContext](#) objects through the [SslContextCreate](#) function. The `SslLib`'s attributes are copied into the new [SslContext](#). Subsequent changes to the `SslLib` won't affect the [SslContext](#) objects that you've already created.
4. **Destruction.** When you're done with your `SslLib` and all of its [SslContexts](#) you should destroy it by passing it to [SslLibDestroy](#). Note that each [SslContext](#) object keeps a reference to the `SslLib` that calved it, so you mustn't destroy an `SslLib` until after its [SslContext](#) objects have been freed.

You can create as many `SslLib` objects as you want, but you typically only create one per application.

# SSL Structures

---

## SslCallback

The `SslCallback` structure contains information about a callback function that's invoked during SSL operations.

```
typedef struct {
    void *reserved;
    SslLibCallbackFunc callback;
    void *data;
    SslContext *ssl;
} SslCallback
```

The fields are:

---

|                       |                                                                                                                                                                                                                          |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>callback</code> | A pointer to a callback function.                                                                                                                                                                                        |
| <code>data</code>     | A pointer to data that's passed to the callback function when it's invoked.                                                                                                                                              |
| <code>ssl</code>      | The SSL context to which the callback applies, or <code>NULL</code> if it's not specific to a context. You never set this field; it's set for you when the callback is copied into an <a href="#">SslContext</a> object. |
| <code>reserved</code> | Reserved for future use.                                                                                                                                                                                                 |

---

There are two types of callback functions: info and verify. The info callback is called as data is being read, when the server sends an alert, and so on. The verify callback is called when a certificate is being verified.

To register a callback function, you create an `SslLibCallback` structure, fill out the `callback` and `data` fields, and then use the structure to set the value of the [InfoCallback](#) or

[VerifyCallback](#) attribute. To set the attribute you call one of these macros:

- [SslLibSet\\_InfoCallback](#) sets the [InfoCallback](#) attribute of an [SslLib](#) object.
- [SslLibSet\\_VerifyCallback](#) sets the [VerifyCallback](#) attribute of an [SslLib](#) object.
- [SslContextSet\\_InfoCallback](#) sets the [InfoCallback](#) attribute of an [SslContext](#) object.
- [SslContextSet\\_VerifyCallback](#) sets the [VerifyCallback](#) attribute of an [SslContext](#) object.

When you register an info callback you must also set the [InfoInterest](#) attribute by calling [SslLibSet\\_InfoInterest](#) or [SslContextSet\\_InfoInterest](#) macro. The [InfoInterest](#) attribute contains a list of the events that your info callback is interested in.

As with (nearly) all SSL attributes, the callbacks that you set in an [SslLib](#) are copied into the [SslContext](#) objects that it spawns.

You can use the same [SslLibCallback](#) structure to set more than one callback function. After you've called a callback-registering macro, you can free the original [SslLibCallback](#) structure.

The protocol for the callback functions is described in [SslCallbackFunc](#), in [Chapter 80, "SSL Functions."](#)

**New**

## **SslCipherSuiteInfo**

Structure that contains information about the cipher suite that's being used. The structure is stored in the [CipherSuiteInfo](#) attribute.

```
typedef struct SslCipherSuiteInfo_st {
    UInt8  cipherSuite[2];
    UInt16 cipher;
    UInt16 digest;
    UInt16 keyExchange;
    UInt16 authentication;
    UInt16 version;
```

## SSL Structures and Data Types

### SSL Structures

---

```
    UInt16  cipherBitLength;  
    UInt16  cipherKeyLength;  
    UInt16  keyExchangeLength;  
    UInt16  authenticationLength;  
    UInt16  export;  
} SslCipherSuiteInfo;
```

The fields are:

---

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cipherSuite</code> | <p>A two-byte value that represents the current cipher suite. The possible values, encoded as constants, are:</p> <ul style="list-style-type: none"><li>0: No cipher suite is being used.</li><li><code>sslCs_RSA_RC4_56_SHA1</code>: Secure Hash Algorithm-1, 56-bit</li><li><code>sslCs_RSA_RC4_128_SHA1</code>: Secure Hash Algorithm-1, 128-bit.</li><li><code>sslCs_RSA_RC4_40_MD5</code>: Rivest Message Digest 5, 40-bit.</li><li><code>sslCs_RSA_RC4_128_MD5</code>: Rivest Message Digest 5, 128-bit.</li></ul> |
| <code>cipher</code>      | <p>A constant that represents the cipher that's being used for this connection:</p> <ul style="list-style-type: none"><li><code>sslCsiCipherNull</code>: No cipher currently set.</li><li><code>sslCsiCipherRc4</code>: RSA RC4.</li></ul>                                                                                                                                                                                                                                                                               |
| <code>digest</code>      | <p>A constant that represents the message digest format.:</p> <ul style="list-style-type: none"><li><code>sslCsiDigestNull</code>: No message digest.</li><li><code>sslCsiDigestMd2</code>: Rivest Message Digest 2.</li><li><code>sslCsiDigestMd5</code>: Rivest Message Divest 5.</li><li><code>sslCsiDigestSha1</code>: Secure Hash Algorithm-1.</li></ul>                                                                                                                                                            |
| <code>keyExchange</code> | <p>A constant that represents the key exchange type that's being used:</p> <ul style="list-style-type: none"><li><code>sslCsiKeyExchNull</code>: No key exchange.</li><li><code>sslCsiKeyExchRsa</code>: RSA.</li></ul>                                                                                                                                                                                                                                                                                                  |

---

---

|                                   |                                                                                                                                                                                                                       |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>authentication</code>       | A constant that represents the authentication type that's being used:<br><br><code>sslCsiAuthNull</code> : No key exchange.<br><code>sslCsiAuthRsa</code> : RSA.                                                      |
| <code>version</code>              | The SSL version number.                                                                                                                                                                                               |
| <code>cipherBitLength</code>      | The length of the material used for encryption key generation, in bits. For export ciphers this will be either 40 or 56 bits.                                                                                         |
| <code>cipherKeyLength</code>      | The length of the encryption key that's generated, in bits. For an export RC4 cipher, the <code>cipherKeyLength</code> is 128.                                                                                        |
| <code>keyExchangeLength</code>    | The length of the public key used to establish a shared secret, in bits.                                                                                                                                              |
| <code>authenticationLength</code> | The length of the public key used to ensure that the key exchange wasn't tampered with, in bits. For export ciphers, the <code>keyExchangeLength</code> is often shorter than the <code>authenticationLength</code> . |
| <code>export</code>               | A boolean value: 1 if an export cipher is being used; 0 otherwise.                                                                                                                                                    |

---

The list of possible cipher suites can be retrieved from the [CipherSuites](#) attribute. The suite that's currently being used is given by the [CipherSuite](#) attribute.

**New**

### SslExtendedItem

Structure that's used to describe a single certificate-related item. Every `SslExtendedItem` has a distinct (pre-defined) "extended item type." The location of the item's data is indicated by the structure—the data isn't stored in the structure.

You never create `SslExtendedItem` structures yourself. The objects that relate to a particular certificate are collected into an

## SSL Structures and Data Types

### SSL Structures

---

[SslExtendedItems](#) structure and returned to you (principally) by your verify callback function.

```
typedef struct SslExtendedItem_st {
    UInt16  type;
    UInt16  field;
    UInt16  dataType;
    UInt16  len;
    UInt32  offset;
} SslExtendedItem;
```

The fields are:

---

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| type     | The extended item type, one of:<br><br>sslExItemTypeX509: X.509 Certificate<br>sslExItemTypeRSA: RSA public key<br>sslExItemTypeRDN: An X.509 Relative Distinguished Name (RDN). This is the certificate's name. Each certificate contains two names, the <i>Subject</i> of the certificate and the <i>Issuer</i> of the certificate. Both are encoded as RDNs that contain multiple fields.<br><br>sslExItemTypeX509Ex: X.509 certificates can contain multiple "extensions." This type is used to specify that the item is a certificate extension. |
| field    | Type-specific value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| dataType | The encoding for the item's data. For the SSL library, the value is one of the ASN.1 encoding types, as listed in <code>SslLibAsn1.h</code> . The encoding is relevant if you're trying to display the data bytes.                                                                                                                                                                                                                                                                                                                                    |

|        |                                                                                                                                                             |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| len    | Number of data bytes.                                                                                                                                       |
| offset | Location of the data itself, as an offset in bytes from the beginning of the <a href="#">SslExtendedItems</a> structure that contains this SslExtendedItem. |

  
**New**

**SslExtendedItems**

Structure that contains a set of related data items that pertain to an SSL certificate or other cryptographic entity. The SslExtendedItems structure is used as part of the [SslVerify](#) structure, and is used as the type of the [PeerCert](#) attribute.

The SslExtendedItems structure is used by the SSL library to return information to your application; you never create and populate an SslExtendedItems structure yourself.

```
typedef struct SslExtendedItems_st
{
    UInt32 length;
    UInt32 num;
    SslExtendedItem eitem[1];
} SslExtendedItems;
```

The fields are:

|        |                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------|
| length | Total length of the structure, in bytes.                                                                     |
| num    | Number of elements in the eitem array.                                                                       |
| eitem  | Individual data items (these are the “related data items” mentioned above). The array contains num elements. |

The items in the eitem array needn’t all be the same “extended item type” (as defined in [SslExtendedItem](#)). For example, the SslExtendedItems structure for a certificate typically contains an sslExItemTypeX509 item, an sslExItemTypeRSA, and an sslExItemType (for the subject name).

## SSL Structures and Data Types

### SSL Structures

---

---

## SslIoBuf

Structure that represents a data I/O operation. It's passed to your info callback function as data is being read or written.

```
typedef struct {
    SslContext *ssl;
    UInt8 *ptr;
    UInt32 outNum;
    UInt32 inNum;
    UInt32 max;
    UInt32 err;
    UInt32 flags;
} SslIoBuf;
```

You can ask for the info callback function to be invoked just before data is read, just after it's read, just before it's written, and just after it's written. You set the [InfoInterest](#) attribute to register for these four events.

Most of the SslIoBuf fields depend on which of these four events is being described:

### Fields

---

|        |                                                                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ctx    | The SSL context that performed the operation.                                                                                                                                                           |
| ptr    | A pointer to the data that was just read, or that's about to be written. For "before read" and "after write" events, the buffer should be empty.                                                        |
| outNum | The number of bytes that were just read or written. For the "before" events, this field is set to 0.                                                                                                    |
| inNum  | The number of bytes that are about to be read or written. For the "before read" case, this is the minimum number of bytes that the context wants to read—the actual number of bytes read may be larger. |

|       |                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| max   | This is valid for the “before read” event only. It’s set to the maximum number of bytes that can be read during the current operation. |
| error | This is set to the error code that was returned by a read operation. It’s only valid for the “after” events.                           |
| flags | Currently ignored.                                                                                                                     |

The information in this structure is provided for debugging and informational purposes only. You could use it, for example, to display the progress of an I/O operation.

| <b>Fields</b>      | <p><b>callback</b><br/>A pointer to a callback function.</p> <p><b>data</b><br/>A pointer to data that’s passed to the function when it’s invoked.</p> <p><b>ssl</b><br/>The SSL context to which the callback applies, or NULL if the structure is owned by an SslLib object.</p> <p><b>reserved</b><br/>Reserved for future use.</p> |

## SSL Structures and Data Types

### SSL Structures

---

**Comments** To register a callback function, create a `SslLibCallback` structure, fill out the `callback` and `data` fields and pass the structure to one of the [SslCallbackFunc](#) functions. The structure is copied into the context, and the `ssl` field is properly set (in the copy).

It's the caller's responsibility to free the original `SslLibCallback` structure. The same `SslLibCallback` structure can be used to set more than one callback function.

For more information, see [SslCallbackFunc](#) in [Chapter 80](#), "[SSL Functions](#)."

---

### SslSession

Structure that represents the current SSL session.

```
typedef struct SslSession_st
{
    UInt32  length;
    UInt16  version;
    unsigned char  cipherSuite[2];
    unsigned char  compression;
    unsigned char  sessionId[33];
    unsigned char  masterSecret[48];
    unsigned char  time[8];
    unsigned char  timeout[4];
    UInt16  certificateOffset;
    UInt16  extraData;
} SslSession;
```

A context's `SslSession` is populated when you call [SslOpen](#). You can retrieve a context's `SslSession` structure and modify it directly—particularly if you want to set the fields that are reserved for application use. To retrieve the `SslSession`, call the [SslContextGet\\_SslSession](#) macro. Keep in mind that this gives you a pointer to the context's internal `SslSession` attribute. If you want to store the `SslSession`, you must copy the attribute's data.

The fields are:

---

|                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>length</code>            | The total size of the structure, in bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>version</code>           | Version number of the SSL protocol that's being used; 0 if the session is using cleartext.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>cipherSuite</code>       | Cipher suite that's being used. See the <a href="#">CipherSuite</a> attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <code>compression</code>       | The name of the compression scheme that's being used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <code>sessionId</code>         | Session identification number. The ID value can be as many as 32 bytes long; the first byte gives the number of valid bytes.                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>masterSecret</code>      | The value of the "master secret" that was established during the SSL handshake.                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>time</code>              | Used to record the time that the session started, using a local time representation. The format can be anything that fits in eight bytes. Unused by the SSL library, an application can use this field as it wishes.                                                                                                                                                                                                                                                                                                                   |
| <code>timeout</code>           | The number of seconds that the session should remain valid. The timeout field is also unused by the SSL library. Use it as you wish.                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>certificateOffset</code> | Offset, in bytes, from the start of the structure to an <a href="#">SslExtendedItems</a> structure that contains the server's certificate. The field is provided for the application's convenience. The SSL library doesn't actually copy the certificate: If you want to cache the server's certificate, you have to retrieve the data through the <a href="#">PeerCert</a> attribute, extend the size of the <code>SslSession</code> structure, copy the certificate data, and then set the <code>certificateOffset</code> yourself. |
| <code>extraData</code>         | Offset, in bytes, from the start of the structure to some extra data that the application keeps for itself. This is similar to the <code>certificateOffset</code> field: You have to allocate, copy, and mark the data yourself.                                                                                                                                                                                                                                                                                                       |

---

## SSL Structures and Data Types

### SSL Structures

---

---

## SslSocket

The `SslSocket` structure contains information about the socket that's being used in the network connection. The structure is defined as:

```
typedef struct {
    NetSocketRef  socket;
    Int16  flags;
    UInt16  addrLen;
    Err  err;
    Int32  timeout;
    NetSocketAddrType  addr;
} SslSocket;
```

You can create your own `SslSocket` structure and add its data to a context through the [SslContextSet\\_IoStruct](#) macro. When you do this, the data in your structure is copied into a structure that's held by the context. Note, however, that the `socket` field isn't copied. To set the socket, use [SslContextSet\\_Socket](#).

The argument values that you pass to [SslSend](#) and [SslReceive](#) are used to modify the context's `SslSocket` structure. If, for example, you create an `SslSocket` with a particular timeout value, set it in a context, and then call [SslSend](#) with a different timeout value (passed as an argument), the latter timeout is recorded in the context's `SslSocket` structure, overriding your original setting.

To retrieve a pointer to the context's `SslSocket`, call [SslContextGet\\_IoStruct](#).

The fields are:

---

|         |                                                                                                                                                                                                                                                                                                                                                                                    |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| socket  | Socket identifier, as created and returned by <code>NetLibSocketOpen</code> . The SSL library doesn't open or connect the socket for you; all socket operations other than reading and writing data must be done through net library calls.<br><br>You never set the <code>socket</code> field directly; use the <a href="#"><code>SslContextSet_Socket</code></a> macro, instead. |
| flags   | Options that control a socket's I/O operations. See <a href="#">I/O Flags</a> in <a href="#">Chapter 61, "Net Library,"</a> on page 1413 for a description of these options.                                                                                                                                                                                                       |
| addr    | The most recent address that the socket read from or wrote to.                                                                                                                                                                                                                                                                                                                     |
| addrLen | The length, in bytes, of the <code>addr</code> field.                                                                                                                                                                                                                                                                                                                              |
| err     | The most recent socket error.                                                                                                                                                                                                                                                                                                                                                      |
| timeout | The socket's I/O operation timeout value, in system ticks.                                                                                                                                                                                                                                                                                                                         |

**New**

---

### SslVerify

Structure that's passed to a verify callback function to provide information about a certificate that's being verified. This happens when the verification process hits a snag, giving your app a chance to handle the problem. The callback is also invoked when the process has successfully completed.

## SSL Structures and Data Types

### SSL Structures

---

```
typedef struct SslVerify_st
{
    SslExtendedItems  *certificate;
    SslExtendedItems  *fieldItems;
    UInt32  field;
    SslExtendedItems  *ex;
    UInt32  depth;
    UInt32  state;
} SslVerify;
```

The fields are:

---

|                     |                                                                                                                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| certificate         | Points to the certificate that's being verified.                                                                                                                                                                            |
| fieldItems<br>field | fieldItems is an array of extended items; field is an index into fieldItems. The <a href="#">SslExtendedItems</a> that's located at fieldItems [ field ] contains the set of items that's causing the problem. (See below.) |
| ex                  | If this is an extension error, the ex field contains the data element of the X509 extension that failed.                                                                                                                    |
| depth               | This is the level of the certificate being processed, where 0 is the server's certificate, and higher numbers are certificates along the "certificate chain" that leads to a trusted root certificate.                      |

---

The list of [SslExtendedItem](#) elements that the [SslExtendedItems](#) object located at fieldItems [ field ] contains depends on the error flavor:

| <b>Flavor</b>                                     | <b>Contents</b>                                                         |
|---------------------------------------------------|-------------------------------------------------------------------------|
| <code>sslErrVerifyBadSignature</code>             | The server's certificate, which contains the public key entries.        |
| <code>sslErrVerifyNoTrustedRoot</code>            | NULL                                                                    |
| <code>sslErrVerifyNotAfter</code>                 | <code>sslExItemTypeX509</code> ,<br><code>asn1FldX509NotAfter</code>    |
| <code>sslErrVerifyNotBefore</code>                | <code>sslExItemTypeX509</code> ,<br><code>asn1FldX509NotBefore</code> . |
| <code>sslErrVerifyConstraintViolation</code>      | <code>asn1ExItemTypeX509Ex</code> (but see below)                       |
| <code>sslErrVerifyUnknownCriticalExtension</code> | <code>asn1ExItemTypeX509Ex</code> (but see below)                       |
| <code>sslErrOk</code>                             | NULL                                                                    |

The `asn1ExItemTypeX509Ex` item needs to be decoded in order to be used. The item contains the "object identifier" part of a certificate extension. The item in the next field (i.e. `fieldItems [ field+1 ]`) depends on the item's `dataType` field: If it's `asn1Boolean`, then the "+1" item contains the extension's optional `Boolean` "this is a critical extension" field, otherwise it contains the extension data itself. If "+1" contains the `Boolean`, then "+2" is the data.

The SSL library attempts to interpret only critical extensions, so the critical field should always be present. If a critical extension isn't understood, the certificate should be rejected.

## **SSL Structures and Data Types**

*SSL Structures*

---

# SSL Attributes and Macros

---

As described in [Chapter 81, “SSL Structures and Data Types,”](#) the [SslLib](#) and [SslContext](#) objects list and describe the properties, or **attributes**, of an SSL context.

There are a number of SSL attributes: Some provide general-purpose information that any SSL session needs, some are used only for specific protocols, some are provided for debugging purposes, and so on.

Associated with each attribute is a set of macros that get and set the attribute’s value.

This chapter lists and describes the SSL attributes, how they’re used, the values that they take (including defaults), and the macros that access them:

- “[SSL Macro Names](#)” explains how the macro names are formed, and how they correspond to the SSL attributes.
- “[SSL Attribute Data Types](#)” talks about the types of data an attribute can represent.
- “[SSL Macro Pseudo-Protocol](#)” provides a pseudo-protocol for the macros.
- “[SSL Attributes](#)” lists the attributes in alphabetical order.
- “[SSL Attribute Constants](#)” is a list of constants that represent the attributes in the attribute-setting functions (which you can use instead of the macros, although it isn’t recommended; the functions are explained below).

## SSL Macro Names

An SSL attribute is accessed through a set of (as many as) four macros: There’s a macro that lets you set an attribute’s value in an

## SSL Attributes and Macros

### SSL Attribute Data Types

---

[SslLib](#), another that sets the attribute's value in an [SslContext](#), and two others that retrieve attribute values from these objects.

The names of the four macros for a given attribute follow this pattern:

- `SslLibSet_Attribute` sets the attribute in an [SslLib](#).
- `SslLibGet_Attribute` gets the attribute from an [SslLib](#).
- `SslContextSet_Attribute` sets the attribute in an [SslContext](#).
- `SslContextGet_Attribute` gets the attribute from an [SslContext](#).

For example, the four macros that set and get the [Mode](#) attribute are:

- `SslLibSet_Mode`
- `SslLibGet_Mode`
- `SslContextSet_Mode`
- `SslContextGet_Mode`

Note that not all attributes require all four macros: Some attributes are read-only, while others apply only to [SslContext](#) objects.

The macros are covers for the eight attribute-setting functions described in [Chapter 80, "SSL Functions,"](#) on page 2135. It's recommended that you use the macros rather than the functions, but you should be aware of the functions' existence.

## SSL Attribute Data Types

An SSL attribute is either an integer or a pointer. For pointer attributes, the type of the pointed-to data depends on the attribute. The descriptions below explicitly state these data types. (The macro declarations in the `SslLibMac.h` file don't include the data types.)

When setting a pointer attribute, the pointed-to data is (almost always) copied into the [SslLib](#) or [SslContext](#). The original data needn't be preserved—the caller is free to destroy the original data when the pointer-setting macro returns. The exceptions to this rule are pointed out in the macro descriptions, below.

To retrieve a pointer attribute, you pass in the address of a pointer; the macro will reset the pointer to data that belongs to the [SslLib](#) or [SslContext](#). You mustn't free or otherwise modify this data.

The macros that set and get integer attributes are defined in terms of the [SslLibSetLong](#), [SslLibGetLong](#), [SslContextSetLong](#), and [SslContextGetLong](#) functions, described in [Chapter 80, "SSL Functions,"](#) on page 2135. The pointer-accessing macros are covers for an analogous set of functions ([SslLibSetPtr](#), *et al.*). You should rarely need to call these functions directly—they're meant to be called by the attribute macros.

## SSL Macro Pseudo-Protocol

This section provides pseudo-protocol for the attribute macros.

**New**

### **SslContextGet\_Attribute (integer version)**

- Purpose** Returns the value of an integer-valued attribute that's stored in an [SslContext](#) object. This is a cover for the [SslContextGetLong](#) function.
- Prototype** `Int32 SslContextSet_Attribute ( UInt16 libRef, SslContext *context )`
- Parameters**
- > libRef (68k only) SSL library reference number.
  - > context The [SslContext](#) that owns the attribute.
- Result** Returns the attribute's value, or a negative-valued error code as described in [SslContextGetLong](#).

## SSL Attributes and Macros

SSL Macro Pseudo-Protocol

---

### **New** **SslContextGet\_Attribute (pointer version)**

**Purpose** Gets a pointer-valued attribute from an [SslContext](#) object. This is a cover for the [SslContextGetPtr](#) function.

**Prototype** `Int32 SslContextGet_Attribute ( UInt16 libRef, SslContext *context, void **data )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context The [SslContext](#) that owns the attribute.
- > data The macro resets \*data so it points to the attribute's data. Unless otherwise noted, the pointed-to data belongs to the [SslContext](#) and shouldn't be freed.

**Result** Returns 0 upon success; see [SslContextGetPtr](#) for error return values.

### **New** **SslLibSet\_Attribute (integer version)**

**Purpose** Sets an integer-valued attribute in an [SslContext](#) object. This is a cover for the [SslLibSetLong](#) function.

**Prototype** `Err SslLibSet_Attribute ( UInt16 libRef, SslContext *context, Int32 value )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context The [SslContext](#) that owns the attribute.
- > value The value you want to set the attribute to.

**Result** Returns 0 upon success; see [SslLibSetLong](#) for error return values.

  
**New** **SslContextSet\_Attribute (pointer version)**

**Purpose** Sets a pointer-valued attribute in an [SslContext](#) object. This is a cover for the [SslContextSetPtr](#) function.

**Prototype** `Err SslContextSet_Attribute ( UInt16 libRef, SslContext *context, void *data )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > context The [SslContext](#) that owns the attribute.
- > data A pointer to the data that you want to set.

**Result** Returns 0 upon success; see [SslContextSetPtr](#) for error return values.

**Comments** The data from data is copied into the [SslContext](#). You can free the original data after the macro returns.

  
**New** **SslLibGet\_Attribute (integer version)**

**Purpose** Returns the value of an integer-valued attribute that's stored in an [SslLib](#) object. This is a cover for the [SslLibGetLong](#) function.

**Prototype** `Int32 SslLibSet_Attribute ( UInt16 libRef, SslLib *lib )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > lib The [SslLib](#) that owns the attribute.

**Result** Returns the attribute's value, or a negative-valued error code

## SSL Attributes and Macros

SSL Macro Pseudo-Protocol

---

### **New** **SslLibGet\_Attribute (pointer version)**

**Purpose** Gets a pointer-valued attribute from an [SslLib](#) object. This is a cover for the [SslLibGetPtr](#) function.

**Prototype** `Int32 SslLibGet_Attribute ( UInt16 libRef,  
SslLib *lib, void **data )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > lib The [SslLib](#) that owns the attribute.
- > data The macro resets \*data so it points to the attribute's data. Unless otherwise noted, the pointed-to data belongs to the [SslLib](#) and shouldn't be freed.

**Result** Returns 0 upon success; see [SslLibGetPtr](#) for error return values.

### **New** **SslLibSet\_Attribute (integer version)**

**Purpose** Sets an integer-valued attribute in an [SslLib](#) object. This is a cover for the [SslLibSetLong](#) function.

**Prototype** `Err SslLibSet_Attribute ( UInt16 libRef,  
SslLib *lib, Int32 value )`

**Parameters**

- > libRef (68k only) SSL library reference number.
- > lib The [SslLib](#) that owns the attribute.
- > value The value you want to set the attribute to.

**Result** Returns 0 upon success; see [SslLibSetLong](#) for error return values.

**New** SslLibSet\_Attribute (pointer version)

- Purpose** Sets a pointer-valued attribute in an [SslLib](#) object. This is a cover for the [SslLibSetPtr](#) function.
- Prototype** `Err SslLibSet_Attribute ( UInt16 libRef, SslLib *lib, void *data )`
- Parameters**
- > libRef (68k only) SSL library reference number.
  - > lib The [SslLib](#) that owns the attribute.
  - > data A pointer to the data that you want to set.
- Result** Returns 0 upon success; see [SslLibSetPtr](#) for error return values.
- Comments** The data from data is copied into the [SslLib](#). You can free the original data after the macro returns.

## SSL Attributes

**New** AppInt32

Convenient Int32 datum that the application can use for whatever purpose it wants—as an object ID, for example. Note that the value is *not* copied from an [SslLib](#) into the [SslContexts](#) that it spawns.

**type:** Int32

**macros:** SslLibSet\_AppInt32  
 SslLibGet\_AppInt32  
 SslContextSet\_AppInt32  
 SslContextGet\_AppInt32

## New AppPtr

Convenient pointer that the application can use for whatever purpose it wants.

**type:** (void \*)

The application retains ownership of the pointed-to data. The data is *not* copied into the [SslLib](#) or [SslContext](#).

**macros:** SslLibSet\_AppPtr  
SslLibGet\_AppPtr  
SslContextSet\_AppPtr  
SslContextGet\_AppPtr

## New AutoFlush

Enables/disables automatic flushing of data after an [SslSend](#) or [SslWrite](#).

**type:** Int32

**values:** 0: Autoflush is turned off.

1: Autoflush is turned on.

**default:** 1 (autoflush on)

**macros:** SslLibSet\_AutoFlush  
SslLibGet\_AutoFlush  
SslContextSet\_AutoFlush  
SslContextGet\_AutoFlush

When enabled, [SslFlush](#) is automatically called after every call to [SslSend](#) and [SslWrite](#). If you have autoflush disabled, you have to call the [SslFlush](#) function yourself. You don't have to call it after *every* [SslSend](#) or [SslWrite](#), but you *do* have to call it before the [SslContext](#)'s write buffer fills up.

The write buffer's size is given by [WbufSize](#); the amount of data that's currently in the buffer is given by [WriteBufPending](#)

---

## BufferedReuse

Allows the last message in an SSL handshake to be buffered. This only applies if [SessionReused](#) is true (non-zero).

**type:** Int32

**values:** 0: Don't buffer the last handshake message.  
non-zero: Buffer the last handshake message.

**macros:** SslContextGet\_BufferedReuse

As described in [SessionReused](#), the handshake involved in re-establishing a previous session can be a truncated version of a normal handshake. At the end of the truncated handshake, the SSL library sends a message to the server. The `BufferReuse` attribute, if enabled, will buffer the last message of the reused handshake instead of sending it over the network. The message will be sent when the application sends its first "real" data.

If you have `BufferReuse` enabled, you must make sure that the final handshake message actually gets sent before reading any incoming data.

There are security implications, here, in that a man-in-the-middle attack could only be detected once the first data bytes are read from the server. In other words, an attacker could have read all the bytes in the first "real data" message sent to the server. For this reason this attribute should not normally be used.

---

### CipherSuite

Represents the cipher suite that's currently in use in this context. [SslContext](#) only, read only.

**type:** (UInt8 \*)

**values:** Each suite is represented by a two-byte value.

0: No cipher suite is being used.

`sslCs_RSA_RC4_56_SHA1`: Secure Hash Algorithm-1, 56-bit

`sslCs_RSA_RC4_128_SHA1`: Secure Hash Algorithm-1, 128-bit.

`sslCs_RSA_RC4_40_MD5`: Rivest Message Digest 5, 40-bit.

`sslCs_RSA_RC4_128_MD5`: Rivest Message Digest 5, 128-bit.

**macros:** `SslContextGet_CipherSuite`

**See Also** [CipherSuites](#)

---

### CipherSuiteInfo

Returns information about the cipher suite or certificate that's currently being used. [SslContext](#) only, read only.

**type:** ([SslCipherSuiteInfo](#) \*)

The [SslCipherSuiteInfo](#) structure must be allocated before it's passed in. The caller retains ownership of the structure.

**values:** The structure is populated by the context. For information on what the structure contains, see [SslCipherSuiteInfo](#).

**macros:** `SslContextGet_CipherSuiteInfo`

To return *just* the cipher suite (without the surrounding information), get the [CipherSuite](#) attribute.

**New**

---

## CipherSuites

Contains a list of cipher suites that the client supports, in order of preference.

**type:** (UInt8 \*)

**values:** Each element in the list takes two bytes. The first two byte element give the sizes of the rest of the list, in bytes (i.e. the “size bytes” themselves aren’t counted in the measurement). The rest of the list is made up of the following (two-byte) constants:

```
sslCs_RSA_RC4_128_MD5
sslCs_RSA_RC4_128_SHA1
sslCs_RSA_RC4_56_SHA1
sslCs_RSA_RC4_40_MD5
```

The data in the list is given in network byte order.

**default:** The default list contains {0x00, 0x08} followed by the suites listed above, in order. To restore the default list, pass a NULL pointer.

**macros:** SslLibSet\_CipherSuites  
SslLibGet\_CipherSuites  
SslContextSet\_CipherSuites  
SslContextGet\_CipherSuites

As an example, the following code creates a list of the strong encryption suites (only) and sets it into an [SslLib](#):

---

```
static UInt8 cipherSuites[]={
    0x00,0x04,
    sslCs_RSA_RC4_128_MD5,
    sslCs_RSA_RC4_128_SHA1
};

SslLibSet_CipherSuites(lib,cipherSuites);
```

---

## SSL Attributes and Macros

### SSL Attributes

---

The cipher suites list is used when the client and server negotiate for an acceptable suite. The suite that's chosen is represented by the [CipherSuite](#) attribute.

---

### Compat

Allows compatibility with malformed or incorrect SSL messages sent from the server

**type:** Int32

**values:** 0: No incompatibility allowed.

If non-zero, the value should be a combination of the following flags.

`sslCompatReuseCipherBug`: Allows servers to change cipher suites on session-reuse.

`sslCompatNetscapeCaDnBug`: Supports old versions of Netscape servers that encode "Distinguished Names" certificates incorrectly. (Note that this isn't currently an issue since the SSL library doesn't support client certificates.)

`sslCompat1RecordPerMessage`: Ensures that SSL messages aren't broken across records. (Some servers don't like to receive SSL messages separated into multiple SSL records.)

`sslCompatBigRecords`: Supports records larger than 16k bytes. (In SSLv3, record size is normally limited to 16k.)

`sslCompatAll`: Enables all the foregoing.

**default:** 0

**macros:** `SslLibSet_Compat`  
`SslLibGet_Compat`  
`SslContextSet_Compat`  
`SslContextGet_Compat`

**New** **DontSendShutdown**

Avoid sending a shutdown message.

**type:** Int32

**values:** 0: Send the shutdown message.  
non-zero: Don't send the shutdown message.

**default:** 0

**macros:** SslLibSet\_DontSendShutdown  
SslLibGet\_DontSendShutdown  
SslContextSet\_DontSendShutdown  
SslContextGet\_DontSendShutdown

When [SslClose](#) is called, the two SSL endpoints swap shutdown messages. You can suppress transmission of the local message by setting this attribute.

To ignore the remote shutdown message, set the [DontWaitForShutdown](#) attribute.

**New** **DontWaitForShutdown**

Avoid waiting for reception of the server's shutdown message.

**type:** Int32

**values:** 0: Wait for the shutdown message.  
non-zero: Don't wait the shutdown message.

**default:** 0

**macros:** SslLibSet\_DontWaitForShutdown  
SslLibGet\_DontWaitForShutdown  
SslContextSet\_DontWaitForShutdown  
SslContextGet\_DontWaitForShutdown

See [DontSendShutdown](#) for details.

## SSL Attributes and Macros

### SSL Attributes

---

#### **New** Error

---

Stores the most recent fatal error code. [SslContext](#) only.

**type:** Int32

**values:** 0: No error

non-zero: An error occurred somewhere up to here.

Note that SslErrIo errors are exempt (they're not considered to be fatal).

**default:** 0

**macros:** SslContextSet\_Error  
SslContextGet\_Error

After you read an Error value, you should set the attribute's value back to 0. The value is reset during an SSL Reset, but it otherwise holds the latest fatal error code.

#### **New** HsState

---

Current SSL state. [SslContext](#) only, read only. Used primarily for debugging.

**type:** Int32

**values:** Defined by the SSL protocol.

**macros:** SslContextGet\_HsState

#### **New** InfoCallback

---

Identifies the callback function that's called at particular moments in an SSL transaction.

**type:** ([SslCallback](#) \*)

**default:** none

**macros:** SslLibSet\_InfoCallback  
SslLibGet\_InfoCallback  
SslContextSet\_InfoCallback  
SslContextGet\_InfoCallback

If you set the InfoCallback attribute, you must also set the [InfoInterest](#) attribute to register for the notifications that you want.

See the [SslCallbackFunc](#) description in [Chapter 80, “SSL Functions,”](#) on page 2135 for more information about the callback functions.

---

### InfoInterest

Specifies the events for which the callback function identified by the [InfoCallback](#) attribute will be called.

**type:** Int32

**values:** The value is formed as a combination of the following (or 0 if you don't want your callback to be called):

`sslFlgInfoAlert`: The callback wants to know about alert notifications. In an alert, the function receives `sslArgInfoAlert` as its command argument.

`sslFlgInfoHandshake`: The callback wants to know about handshake notifications (`sslArgInfoHandshake`).

`sslFlgInfoIO`: The callback wants to be called before and after each [SslCallback](#) operation (`sslArgInfoReadBefore`, `sslArgInfoReadAfter`, `sslArgInfoWriteBefore`, `sslArgInfoWriteAfter`).

`sslFlgInfoCert`: The callback wants to know about certificate notifications (`sslArgInfoCert`).

**default:** 0

**macros:** `SslLibSet_InfoInterest`  
`SslLibGet_InfoInterest`  
`SslContextSet_InfoInterest`  
`SslContextGet_InfoInterest`

For these to be effective, you must set an info callback function (see [InfoCallback](#)).

For more information on how the callback functions work, and for detailed specifications of the command values referred to above, see the [SslCallbackFunc](#) description in [Chapter 80, "SSL Functions,"](#) on page 2135.

**New**

---

## IoTimeout

Amount of time that an I/O operation should wait for a response from the other side of the network connection before it gives up and returns an error. The timeout is measured in ticks.

**type:** Int32

**values:** [0, 0xffffffff].

**default:** 10 seconds

**macros:** SslContextSet\_IoTimeout  
SslContextGet\_IoTimeout

Individual SSL library functions can specify their own timeout values. In the absence of a timeout specification, the IoTimeout value is used.

**New**

---

## IoFlags

Socket I/O flags that are used by the data read and write functions. [SslContext](#) only.

**type:** Int32

**values:** See the “[I/O Flags](#)” on page 1421 for a list of these flags. netIOFlagOutOfBand and netIOFlagPeek don't apply; they're twiddled out of the value you supply.

**default:** none

**macros:** SslContextSet\_IoFlags  
SslContextGet\_IoFlags

## **New** IoStruct

[SslSocket](#) structure that holds arguments that are passed to the underlying net library functions. [SslContext](#) only.

**type:** ([SslSocket](#) \*)

**values:** See [SslSocket](#).

**default:** ([SslSocket](#) \*) NULL

**macros:** SslContextSet\_IoStruct  
SslContextGet\_IoStruct

When you call `SslContextSet_IoStruct`, the `socket` field of the [SslSocket](#) that you pass in is ignored. Use the [Socket](#) attribute to set the socket.

The structure's other fields correspond to the arguments to the [SslSend](#) and [SslReceive](#) functions (which see for details). When you call one of these functions, the arguments that you pass are copied into the context's [SslSocket](#) structure. Thus, the [SslSocket](#) configuration that you set through `SslContextSet_IoStruct` may be updated when you call an I/O function.

## **New** LastAlert

Most recent fatal error code. [SslContext](#) only, read only.

**type:** Int32

**values:** See the `sslAlertType` constants in `SslLibMac.h`.

**default:** 0

**macros:** SslContextGet\_LastAlert

An alert is an error or status code that's sent by the server. Alerts can be fatal or non-fatal. Fatal alerts are in the form 0x02xx; non-fatal alerts are 0x01xx, as shown below:

```
Int32 alert;

SslContextGet_LastAlert( context, &alert);

if ( alert != 0 ) {
    if ( alert & 0x0f00 == 0x0200 )
        /* fatal */
    else if ( alert & 0x0f00 == 0x0100 )
        /* non-fatal */
    else
        /* undefined */
}
```

---

---

## **New** LastApi

Represents the most recently called SSL library function.  
[SslContext](#) only, read only.

**type:** Int32

**values:** sslLastApiNone: No SSL library function call in this context since the last SSL reset.

sslLastApiRead: The previous function was [SslOpen](#).

sslLastApiRead: The previous function was [SslRead](#), [SslPeek](#), or [SslReceive](#).

sslLastApiWrite: The previous function was [SslWrite](#) or [SslSend](#).

sslLastApiFlush: The previous function was [SslFlush](#).

sslLastApiShutdown: The previous function was [SslClose](#).

**macros:** SslContextGet\_LastApi

## SSL Attributes and Macros

### SSL Attributes

---

---

### LastIO

Represents the nature of the previous I/O operation. [SslContext](#) only, read only.

**type:** Int32

**values:** `sslLastIoNone`: There is yet to be an I/O operation in this context since the last SSL reset.

`sslLastIoRead`: The previous I/O operation was a read.

`sslLastIoWrite`: The previous I/O operation was a write.

**default:** `sslLastIoNone`

**macros:** `SslContextGet_LastIO`

This attribute can be useful when you're determining the reason for an error.

---

### Mode

Turns SSL on and off.

**type:** Int32

**values:** `sslModeClear`: SSL is turned off.

`sslModeSsl`: SSL is turned on

`sslModeSslClient`: SSL is turned on, and this endpoint is a client.

`sslModeFlush`: Data-clearing flag. If present, the context's internal data buffers are cleared (the data is lost). This flag is applicable to [SslContexts](#) only.

**default:** `sslModeSslClient`

**macros:** `SslLibSet_Mode`  
`SslLibGet_Mode`  
`SslContextSet_Mode`  
`SslContextGet_Mode`

`sslModeSsl` and `sslModeSslClient` are essentially the same; the only difference is that the latter explicitly declares the object to represent the client side of the connection. In Palm OS 5, SSL endpoints are always clients.

When set to `sslModeClear`, SSL is bypassed. This lets you write your application with the SSL library API and still perform normal (non-SSL) data transfers. Your application will still get the advantage of the data buffering provided by the SSL I/O functions ([SslRead](#), [SslWrite](#), *et al.*).

You can use `sslModeSsl` as a mask to determine if SSL is on:

---

```
If (SslContextGet_Mode(ssl) & sslModeSsl)
    /* SSL protocol enabled */
else
    /* Using cleartext */
```

---

### The Mode Attribute in SslContexts

Setting an [SslContext](#)'s Mode (even if you set it to the status quo) causes an "SSL reset." This sets most of the other SSL attributes back to their default values, and puts the [SslContext](#) in the proper state to open a new SSL session. Note that an SSL reset doesn't clear SSL session information, thus allowing the previous session to be used in a new session with the same server. See [ReadStreaming](#) for details.

To force an SSL reset, do this:

---

```
SslContextSet_Mode(context, SslContextGet_Mode(context));
```

---

Switching from SSL-off to SSL-on initiates a new SSL handshake.

`sslModeFlush` is a flag that, when present, clears the internal read and write buffers. Any data in the buffers is lost. You would normally use this flag when you're reusing an SSL session.

## SSL Attributes and Macros

### SSL Attributes

---

#### **New** PeerCert

Structure that represents the certificate that was supplied by the server. [SslContext](#) only, read only.

**type:** ([SslExtendedItems](#) \*)

**values:** If a certificate is available, the context passes back a pointer to a structure. See [SslExtendedItems](#) for details.

**default:** ([SslExtendedItems](#) \*) NULL

**macros:** `SslContextGet_PeerCert`

#### **New** PeerCommonName

Structure that contains information that you use to retrieve the server's common name from a previously retrieved certificate. [SslContext](#) only, read only.

**type:** ([SslExtendedItem](#) \*)

**values:** See the example, below.

**default:** ([SslExtendedItem](#) \*) NULL

**macros:** `SslContextGet_PeerCommonName`

To use this attribute, you must also retrieve the server's certificate through [SslContextGet\\_PeerCert](#). You then perform some pointer juggling that's best explained through an example:

---

```
SslExtendedItems *cert;
SslExtendedItem *commonName;

/* The length of the common name */
Int16 length;

/* A pointer to the beginning of the common name. */
Int8 *bytes;

SslContextGet_PeerCert( ssl, &cert );
```

```
if ( cert != NULL ) {
    SslContextGet_PeerCommonName( ssl, &commonName );

    /* Get the common name length from the SslExtendedItem
     * struct.
     */
    length = commonName->len;

    /* The name itself is in the peer certificate, located
     * at an offset (into the SslExtendedItems struct) as
     * indicated by the offset field of the SslExtendedItem
     * struct.
     */
    bytes = ((Int8 *)cert) + commonName->offset;

    /* Now that we have a pointer to the name and the
     * length of the name, we can compare it to the
     * expected value.
     */
    StrNCompare ( bytes, expectedValue, length );
}
```

---

If you're using SSL in an https context, for example, the client application should ensure that the common name contained in the server's certificate matches the requested URL.

**New**

---

### ProtocolVersion

The SSL protocol that's being used

**type:** Int32

**values:** sslVersionSSLv3 only; if you set the protocol to some other value, SSL won't work.

**macros:** SslLibSet\_ProtocolVersion  
SslLibGet\_ProtocolVersion  
SslContextSet\_ProtocolVersion  
SslContextGet\_ProtocolVersion

## **New** RbufSize

---

The size of the internal read buffer, in bytes.

**type:** Int32

**values:** [0, 16384]

**default:** 2048

**macros:** SslLibSet\_RbufSize  
SslLibGet\_RbufSize  
SslContextSet\_RbufSize  
SslContextGet\_RbufSize

The actual size of the read buffer may be different from that which you request: The buffer is automatically increased in size if the SSL protocol and/or decryption algorithm demand it. For example, if decryption can only operate on an entire record, and if it's passed a record that's longer than the read buffer size, the buffer will grow to accommodate the record.

The [ReadStreaming](#) attribute describes an advanced use of the read buffer that decreases data reading latency.

## **New** ReadBufPending

---

Returns the number of bytes that are waiting to be read from the context's read buffer. The measurement includes in-coming SSL encryption data. [SslContext](#) only; read only.

**type:** Int32

**values:** [0, 16k]

**macros:** SslContextGet\_ReadBufPending

This attribute is provided for debugging purposes.

**New**

---

## ReadOutstanding

Returns the number of bytes that remain to be read from the current SSL record. [SslContext](#) only; read only.

**type:** Int32

**values:** [0, 16k]

0 means the entire record has been read and verified.

**macros:** SslContextGet\_ReadOutstanding

See [ReadStreaming](#) for a justification of this attribute.

**New**

---

## ReadRecPending

Returns the number of “real” bytes of data in the context’s read buffer. The measurement doesn’t include SSL encryption data. [SslContext](#) only; read only.

**type:** Int32

**values:** [0, 16k]

**macros:** SslContextGet\_ReadRecPending

If this attribute is 0, the next [SslRead](#) or [SslReceive](#) will cause a [NetLibReceive](#) invocation.

**New**

---

## ReadStreaming

Allows partial record data to be read.

**type:** Int32

**values:** 0: Always wait for an entire record before reading.  
non-zero: Don’t wait for an entire record.

## SSL Attributes and Macros

### SSL Attributes

---

**default:** 0

**macros:** SslLibSet\_ReadStreaming  
SslLibGet\_ReadStreaming  
SslContextSet\_ReadStreaming  
SslContextGet\_ReadStreaming

If the network is running at a very low rate (such as a 300 baud modem), you may want to allow in-coming data to be returned to the application before a full record has been downloaded. Notice, however, that “stream reading” has an implication on security: Since you can’t verify the record until it has been fully read, you must be careful what you do with stream read data. You should never respond to in-coming data until an entire record has been read and verified. The [ReadOutstanding](#) attribute can be used to determine if a record has been fully read and verified.

The SSL library may reject stream reading requests. See the [Streaming](#) attribute for details.

To retrieve streaming data, use the [SslPeek](#) and [SslConsume](#) functions (rather than [SslRead](#) or [SslReceive](#)).

---

### SessionReused

Indicates whether the context is reusing a previous session. [SslContext](#) only, read only.

**type:** Int32

**values:** 0: No, this is a new session.  
non-zero: Yes, this session is a continuation of a previous session.

**default:** 0

**macros:** SslContextGet\_SessionReused

SSL can re-establish a previously formed session if both ends of the network connection have a common notion of the session’s parameters (as represented by the [SslSession](#) attribute). Reusing a session lets the SSL protocol use a truncated (faster) handshake.

## New Socket

Specifies the net library socket that an [SslContext](#) will use in I/O operations. [SslContext](#) only.

**type:** [NetSocketRef](#) (Int16)

**default:** none

**macros:** [SslContextSet\\_Socket](#)  
[SslContextGet\\_Socket](#)

An SSL context can't perform any network operations until it's supplied with a valid, open, connected [NetSocketRef](#). The SSL library doesn't perform any Net library operations Creation, initialization, and destruction of the socket that the [NetSocketRef](#) represents is the application's responsibility.

This call is used to specify the net library socket that the [SslContext](#) should use to perform its network I/O operations. A [SslContext](#) is unable to perform any network operation until the application creates and supplies a suitable [NetSocketRef](#).

---

**IMPORTANT:** The SslLib library uses the [NetSocketRef](#) to send data and receive data only—it doesn't call any other net library functions except for [NetLibSend](#) and [NetLibReceive](#). **All socket creation, configuration, and shutdown operations must be performed by the application.**

---

## New SslSession

Structure that represents the current or impending SSL session. [SslContext](#) only.

**type:** ([SslSession](#) \*)

## SSL Attributes and Macros

### SSL Attributes

---

**values:** When a session is opened, the context populates the structure with information. See [SslSession](#) for details.

**macros:** `SslContextSet_SslSession`  
`SslContextGet_SslSession`

You can fine-tune an impending session by creating and populating an [SslSession](#) that you pass in through `SslContextSet_SslSession`. As with most pointer attributes, the structure is copied into the context. The next time you call [SslOpen](#), the embedded [SslSession](#) information is used to configure the session. The structure is then modified, if necessary, to reflect the actual state of the session.

Session information isn't cleared in an SSL reset. Maintaining the session info allows a session to be reused, as discussed in [SessionReused](#).

**New**

---

### SslVerify

Structure that's used during certificate verification. [SslContext](#) only, read only.

**type:** ([SslVerify](#) \*)

**values:** See the example, below.

**default:** ([SslVerify](#) \*) NULL

**macros:** `SslContextGet_SslVerify`

If certification runs into a problem that can't be resolved by the verify callback function (see [VerifyCallback](#)), or if you haven't registered a verify callback function, an error will be returned to your application, which can retrieve the [SslVerify](#) structure in an attempt to solve the conflict itself.

If your application determines that the error isn't fatal, it should clear the error (through [SslContextSet\\_Error](#)) and reinvoke the function that returned the error.

## **New** Streaming

---

Tells you if the context is stream reading. [SslContext](#) only; read only.

**type:** Int32

**values:** 0: The context isn't stream reading.  
non-zero: The context is stream reading.

**macros:** SslContextGet\_Streaming

In some cases, the SSL library may decide that it doesn't want to do stream reading, regardless of the value of the [ReadStreaming](#) attribute. The value of this attribute tells you the truth.

## **New** VerifyCallback

---

Identifies the callback function that's used during certificate verification.

**type:** ([SslCallback](#) \*)

**default:** none

**macros:** SslLibSet\_VerifyCallback  
SslLibGet\_VerifyCallback  
SslContextSet\_VerifyCallback  
SslContextGet\_VerifyCallback

For more information, see the [SslCallbackFunc](#) description in [Chapter 80, "SSL Functions."](#)

## SSL Attributes and Macros

### SSL Attribute Constants

---

#### **New** WbufSize

---

The size of the internal write buffer, in bytes. Note that SSL protocol overhead takes about 30 bytes, so the “writable” portion of the write buffer will be slightly smaller than the value of `WbufSize`.

**type:** `Int32`

**values:** `[0, 16384]`

**default:** `1024`

**macros:** `SslLibSet_WbufSize`  
`SslLibGet_WbufSize`  
`SslContextSet_WbufSize`  
`SslContextGet_WbufSize`

#### **New** WriteBufPending

---

Returns the number of bytes of data in the context’s write buffer (i.e. waiting to be sent to the remote endpoint). [SslContext](#) only; read only.

**type:** `Int32`

**values:** `[0, 16k]`

**macros:** `SslContextGet_WriteBufPending`

This attribute should be zero unless [AutoFlush](#) is disabled. You must explicitly flush (through [SslFlush](#)) before the value of `WriteBufPending` reaches the value of [WbufSize](#) (the maximum size of the write buffer).

## SSL Attribute Constants

As explained earlier, each of the attribute macros is a cover for one of the eight attribute-setting or -getting functions. (The functions are described in [Chapter 80, “SSL Functions,”](#) on page 2135.) Instead of

invoking the attribute macros, you can call the attribute functions, instead.

Unlike the macros, the functions don't correspond to specific attributes. To tell the function which attribute you want it to access, you pass in one of the attribute constants. These constants usually take the form

```
sslAttrLibAttribute
```

or

```
sslAttrAttribute
```

where the former represents the attribute in an [SslLib](#) object, and the latter is the [SslContext](#) version (note the lack of a qualifying "Context" in the names of the [SslContext](#) macro constants). As examples:

- `sslAttrLibMode` represents the [Mode](#) attribute in an [SslLib](#) object.
- `SslAttrMode` is the [Mode](#) attribute in an [SslContext](#).
- `sslAttrLibAutoFlush` and `sslAttrAutoFlush` signify the [AutoFlush](#) attribute in the [SslLib](#) and [SslContext](#).

Note that there are a few exceptions to this formula.

Alphabetical lists of the attribute constants are given below, one list for [SslLib](#) attributes, and a second for [SslContext](#). The constant names that don't conform to the formula, above, are noted.

### SslLib Attribute Constants

```
sslAttrLibAppInt  
sslAttrLibAppPtr  
sslAttrLibAutoFlush  
sslAttrLibBufferedReuse  
sslAttrLibCompat  
sslAttrLibDontSendShutdown  
sslAttrLibDontWaitForShutdown  
sslAttrLibInfoCallback  
sslAttrLibInfoInterest  
sslAttrLibMode  
sslAttrLibProtocolVersion  
sslAttrLibRbufSize  
sslAttrLibReadStream  
sslAttrLibSessionCallback  
sslAttrLibVerifyCallback
```

# SSL Error Codes

---

The SSL functions described in [Chapter 80, “SSL Functions,”](#) return `errNone` if successful, and non-zero otherwise. The table below lists and explains these “non-zero” values.

In addition to the errors listed below, the SSL functions also pass back errors that are returned by the underlying network library (NetLib) functions.

---

**WARNING!** The `sslErrOk` error code, declared in `SslLib.h` is does *not* indicate success. The error-returning SSL functions return `errNone` for success.

---

The errors are grouped under topical headers, and listed alphabetically therein. The groups are:

- [SSL Function Protocol Errors](#) indicate a malformed function call, or other non-SSL dilemma.
- [SSL Alerts](#) are errors that your application may need to explore to find out what really happened.
- [SSL Handshake Errors](#) are returned while SSL handshake messages are being passed between the client and the server.
- [SSL Cryptography Errors](#) indicate that a cryptographic operation has failed.
- [SSL Illegal Message Errors](#) are returned when SSL receives an unexpected message type.
- [SSL Certificate Errors](#) describe the different failures during certificate verification.

## SSL Function Protocol Errors

`sslErrBadArgumentA` function argument was (generally) invalid.

## SSL Error Codes

### SSL Alerts

---

|                                   |                                                                                                                                                                             |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslErrBadLength</code>      | A buffer length argument to a data-reading or -writing function was invalid.                                                                                                |
| <code>sslErrBadOption</code>      | This means the same as <code>sslErrBadArgument</code> .                                                                                                                     |
| <code>sslErrBufferTooSmall</code> | A buffer supplied to this function wasn't big enough for the data that the functions wanted to stuff into it.                                                               |
| <code>sslErrEof</code>            | You attempted to read or write a socket that isn't open.                                                                                                                    |
| <code>sslErrFailed</code>         | General, unspecified error.                                                                                                                                                 |
| <code>sslErrNullArg</code>        | You passed in a NULL argument. This is returned, for example, if you pass in a NULL pointer where a valid <a href="#">SslLib</a> or <a href="#">SslContext</a> is expected. |
| <code>sslErrOutOfMemory</code>    | Not enough memory to allocate the resources that are needed by this function.                                                                                               |

## SSL Alerts

|                               |                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sslErrCbAbort</code>    | Returned by a callback function to indicate that the caller should exit. See <a href="#">SslCallbackFunc</a> in <a href="#">Chapter 80, "SSL Functions."</a>                                                                                                                                                                    |
| <code>sslErrIo</code>         | Indicates that an underlying NetLib function has returned a non-fatal error, such as a timeout. When you get this error, you should try to determine what the exact error is—you usually start by looking at the context's <a href="#">Compat</a> attribute. After you clear the error, you can try to call the function again. |
| <code>sslErrFatalAlert</code> | An SSL fatal alert was received. To handle the alert, see the <a href="#">LastAlert</a> attribute in <a href="#">Chapter 82, "SSL Attributes and Macros."</a>                                                                                                                                                                   |

## SSL Handshake Errors

`sslErrBadPeerFinished`

The final check of the SSL handshake failed. This means that there was a problem establishing a shared secret value. It could be caused by the server using a certificate that does not match its private key.

`sslErrExtraHandshakeData`

An SSL handshake message contained data that shouldn't have been there.

`sslErrHandshakeEncoding`

An error occurred while an SSL handshake message (from the server) was being decoded.

`sslErrHandshakeProtocol`

An error occurred while processing a decoded SSL handshake message.

`sslErrReadAppData`

A handshake message was expected, but application data was read.

## SSL Cryptography Errors

`sslErrCsp`

General cryptography error.

`sslErrDivByZero`

Math error. This can happen if a certificate has an invalid public key.

`sslErrNoModInverse`

Another math error. See above.

`sslErrNoRandom`

There was a problem with the random number source.

## SSL Error Codes

### SSL Illegal Message Errors

---

## SSL Illegal Message Errors

`sslErrBadSignature`

An invalid signature was found on an ephemeral Cipher Suite message.

`sslErrWrongMessage`

An invalid or inappropriate SSL message was received.

`sslErrUnexpectedRecord`

The wrong type of record was received.

`sslErrRecordError`

An invalid record was received by the [SslContext](#).

## SSL Certificate Errors

`sslErrBadDecode`

Something went wrong while decoding values during certificate verification.

`sslErrCert`

General certificate error.

`sslErrCertDecodeError`

The server's certificate could not be decoded.

`sslErrUnsupportedCertType`

The server sent a certificate that isn't supported (it contains a public key that can't be decoded).

`sslErrUnsupportedSignatureType`

The server sent a certificate that has an unrecognized signature type.

`sslErrVerifyBadSignature`

The certificate's signature is invalid

`sslErrVerifyConstraintViolation`

The certificate violates an X509 extension.

`sslErrVerifyNotAfter`

The certificate has expired.

`sslErrVerifyNotBefore`

The certificate is too early (the timestamp window is in the future).

`sslErrVerifyNoTrustedRoot`

A trusted certificate store (necessary for certificate verification) couldn't be found.

`sslErrVerifyUnknownCriticalExtension`

An X509 extension (that's marked as "critical") isn't understood by the certificate verification routines.

## **SSL Error Codes**

*SSL Certificate Errors*

---

# SMS Exchange Library

---

This chapter describes the SMS Exchange Library API declared in the header file `SmsLib.h`. It discusses the following topics:

- [SMS Exchange Library Data Structures](#)
- [SMS Exchange Library Constants](#)

You interact with the SMS Exchange Library using the Exchange Manager APIs described in [Chapter 57, “Exchange Manager,”](#) on page 1297 of this book. For further information on using Exchange Manager, see “[Object Exchange](#)” on page 1 of the of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## SMS Exchange Library Data Structures

### SmsParamsType

The `SmsParamsType` structure identifies information specific to the SMS Exchange Library. The `socketRef` field of the [ExgSocketType](#) structure is set to this structure when you send or receive data using the SMS Exchange Library. You only need to create this structure and assign it to the `socketRef` field if you have an SMS message to send and want to use non-default values for some of the fields; otherwise, the SMS Exchange Library creates this structure for you and provides default values.

```
typedef struct SmsParamsTag
{
    UInt32 creator;
    UInt16 smsID;
    Char *extension;
    Char *mimeTypes;
    UInt32 appCreator;
```

## SMS Exchange Library

### SMS Exchange Library Data Structures

---

```
    UInt8 dataCodingScheme;
    UInt8 networkType;
    UInt8 dataType;
    UInt16 nbsDestPort;
    UInt16 nbsSrcPort;
    union
    {
        SmsSendParamsType send;
        SmsReceiveParamsType receive;
        SmsReportParamsType report;
    } data;
} SmsParamsType, *SmsParamsPtr;
```

#### Field Descriptions

|           |                                                                                                                                                                                                                                           |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| creator   | Creator ID of the SMS Exchange Library. Always set this to <code>sysFileCSmsLib</code> .                                                                                                                                                  |
| smsID     | The ID of the message that was sent. Do not set this field directly; the SMS Exchange Library should set it.                                                                                                                              |
| extension | If the SMS message has an attachment, this field specifies the attachment name. Do not set this field directly; the SMS Exchange Library sets it if necessary. See the <code>appCreator</code> field description for details.             |
| mimeTypes | If the SMS message has an attachment, this field specifies the MIME type of the attachment. Do not set this field directly; the SMS Exchange Library sets it if necessary. See the <code>appCreator</code> field description for details. |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| appCreator       | <p>The creator ID of the target application for the attachment to the SMS message. Do not set this field directly; the SMS Exchange Library sets it if necessary.</p> <p>When the SMS Exchange Library receives a message with an attachment, it unwraps the message and attempts to deliver the attachment directly to an application that is registered to receive it. If no application is registered to receive unwrapped attachments of that type, the SMS Exchange Library sends the entire SMS message, and it sets the <code>extension</code>, <code>mimeType</code>, and <code>appCreator</code> fields in this structure. The SMS application can use this information to have the Exchange Manager deliver the attachment to the appropriate application using the Local Exchange Library.</p> |
| dataCodingScheme | <p>The data encoding scheme that the message uses. See <a href="#">SMS Data Coding Scheme Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| networkType      | <p>Indicates the type of advanced parameters. See <a href="#">SMS Network Type Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| dataType         | <p>Identifies the type of message being received, such as multipart or return receipt. See <a href="#">SMS Message Type Constants</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| nbsDestPort      | <p>The Narrow Band Socket (NBS) port on which you want the data sent. The SMS Exchange Library sets this for you if you leave it blank. When data is being received, this field is set to the NBS port on which the data was received.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## SMS Exchange Library

### SMS Exchange Library Data Structures

---

|            |                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| nbsSrcPort | The NBS port on which you want the data sent. You should set this field to the same value as nbsDestPort. If you leave it blank, the SMS Exchange Library provides a value for you. |
| data       | The data being sent or received. See <a href="#">SmsReceiveParamsType</a> , <a href="#">SmsReportParamsType</a> , and <a href="#">SMSSendParamsType</a> .                           |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsPrefType

The `SmsPrefType` structure defines the SMS Exchange Library preferences for sending and receiving SMS messages. Applications can use the [ExgControl](#) function to get, set, or display these preferences to the user.

```
typedef struct SmsPrefTag
{
    UInt32 validity;
    UInt16 warnOver;
    Boolean leave;
    Boolean report;
    Boolean autoSMSC;
    Char smscNumber[kSmsMaxPhoneSize];
} SmsPrefType, *SmsPrefPtr;
```

### Field Descriptions

|                         |                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>validity</code>   | The number of seconds before the message expires. If the message cannot be delivered to the recipient, the service center repeatedly attempts to deliver the message until it expires. The default is one hour.                                                                                                                  |
| <code>warnOver</code>   | The number of parts a user can send without confirmation. If the user attempts to send a message with more than this number of parts, an alert is displayed, and the user can choose to send the message anyway. The default is 3 parts. (If the user attempts to send a message with more than 3 parts, an alert is displayed.) |
| <code>leave</code>      | If <code>true</code> , any incoming messages retrieved from a phone remain on the phone as well. If <code>false</code> , the messages are deleted from the phone's inbox.                                                                                                                                                        |
| <code>report</code>     | If <code>true</code> , the user receives confirmation that an SMS message was delivered.                                                                                                                                                                                                                                         |
| <code>autoSMSC</code>   | If <code>true</code> , don't use the value stored in the <code>smscNumber</code> field.                                                                                                                                                                                                                                          |
| <code>smscNumber</code> | The message center to be used. If <code>NULL</code> or the empty string, the SMS message center set by the phone is used.                                                                                                                                                                                                        |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### SmsReceiveCDMAParamsType

The [SmsReceiveParamsType](#) includes an `SmsReceiveCDMAParamsType` structure for CDMA messages.

```
typedef struct SmsReceiveCDMAParamsTag
{
    UInt8 messageType;
    TelSmsDateTimeType validityPeriod;
    UInt8 priority;
    UInt8    privacy;
```

## SMS Exchange Library

### SMS Exchange Library Data Structures

---

```
Boolean alertOnDeliveryRequest;  
Boolean manualAckRequest;  
UInt8   voiceMessageNumber;  
UInt8   languageIndicator;  
Char *   callbackNumberAddress;  
} SmsReceiveCDMAParamsType,  
*SmsReceiveCDMAParamsPtr;
```

#### Field Descriptions

|                        |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| messageType            | The type of the message. This is one of the <a href="#">SMS Message Type Constants</a> constants defined in <code>TelephonyMgr.h</code> .        |
| validityPeriod         | The amount of time for which the message is valid. See <a href="#">TelSmsDateTimeType</a> . The default is set according to the SMS preferences. |
| priority               | The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> defined in <code>TelephonyMgr.h</code> .             |
| privacy                | The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> defined in <code>TelephonyMgr.h</code> .  |
| alertOnDeliveryRequest | true if the user is to be alerted upon delivery of this message, and false if not.                                                               |
| manualAckRequest       | true if a confirmation is requested from the recipient, and false if not.                                                                        |
| voiceMessageNumber     | The number of new messages in your voice mail.                                                                                                   |

|                       |                                                            |
|-----------------------|------------------------------------------------------------|
| languageIndicator     | Reserved for future use.                                   |
| callbackNumberAddress | The callback number to which confirmations are to be sent. |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsReceiveGSMPParamsType

The [SmsReceiveParamsType](#) includes an `SmsReceiveGSMPParamsType` structure for GSM messages.

```
typedef struct SmsReceiveGSMPParamsTag
{
    UInt16 protocolId;
    Char *serviceCenterNumber;
    Boolean replyPath;
} SmsReceiveGSMPParamsType,
*SmsReceiveGSMPParamsPtr;
```

### Field Descriptions

|                     |                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------|
| protocolId          | Reserved for future use.                                                                                                    |
| serviceCenterNumber | The SMS service center that must be used to send a reply. If NULL, the service center specified in the preferences is used. |
| replyPath           | If true, replies must be made through the SMS service center specified by <code>serviceCenterNumber</code> .                |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsReceiveParamsType

The `SmsReceiveParamsType` structure is used as the data field for the [SmsParamsType](#) structure when the SMS Exchange Library

## SMS Exchange Library

### SMS Exchange Library Data Structures

---

has received data. The SMS Exchange Library always supplies the values for these fields.

```
typedef struct SmsReceiveParamsTag
{
    UInt32 timeStamp;
    Char *originatingAddress;
    UInt8 leaveOnPhone:1;
    UInt8 forceSlotMode:1;
    UInt8 reserved:6;
    UInt16 index;
    Boolean otherToReceive;
    Boolean reportDeliveryIndicator;
    union
    {
        SmsReceiveGSMParamsType gsm;
        SmsReceiveCDMAParamsType cdma;
        SmsReceiveTDMAParamsType tdma;
    } protocol;
} SmsReceiveParamsType, *SmsReceiveParamsPtr;
```

#### Field Descriptions

|                                 |                                                                                                                                                                  |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>timeStamp</code>          | The time at which the message was delivered, given as the number of seconds since January 1, 1904.                                                               |
| <code>originatingAddress</code> | The number from which the message was received.                                                                                                                  |
| <code>leaveOnPhone</code>       | If <code>true</code> , messages received on the phone are not deleted from the phone's inbox. If not specified, this is set according to the system preferences. |
| <code>forceSlotMode</code>      | If <code>true</code> , use slot mode parsing. If <code>false</code> , use block mode parsing. The default is block mode.                                         |
| <code>reserved</code>           | Reserved for future use.                                                                                                                                         |

|                         |                                                                                                                                                         |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| index                   | Location where the message is stored on the mobile phone.                                                                                               |
| otherToReceive          | If <code>true</code> , there are more messages to be received from the service center.                                                                  |
| reportDeliveryIndicator | If <code>true</code> , the sender has requested confirmation. The recipient of the message does not send the confirmation; the SMS service center does. |
| protocol                | Values specific to the protocol used to send the message. Currently, only GSM is supported.                                                             |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### **SmsReceiveTDMAParamsType**

The [SmsReceiveParamsType](#) includes an `SmsReceiveTDMAParamsType` structure for TDMA messages. This structure is currently the same as the [SmsReceiveCDMAParamsType](#) structure.

```
typedef SmsReceiveCDMAParamsType
    SmsReceiveTDMAParamsType,
    *SmsReceiveTDMAParamsPtr;
```

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### **SmsReportParamsType**

The `SMSReportParamsType` structure is used as the data field for the [SmsParamsType](#) structure when the SMS Exchange Library has received a delivery confirmation. The SMS Exchange Library always sets the values for these fields.

```
typedef struct SmsReportParamsTag
{
    UInt32 timeStamp;
```

## SMS Exchange Library

### SMS Exchange Library Data Structures

---

```
    UInt16 index;
    UInt8  reportType;
    UInt8  report;
    Char*  originatingAddress;
} SmsReportParamsType, *SmsReportParamsPtr;
```

#### Field Descriptions

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| timeStamp          | The date and time at which the message was delivered, given as the number of seconds since January 1, 1904. |
| index              | Location where the message is stored on the mobile phone.                                                   |
| reportType         | One of the Delivery Report Type constants defined in <code>TelephonyMgr.h</code> .                          |
| report             | One of the Delivery Status Report constants defined in <code>TelephonyMgr.h</code> .                        |
| originatingAddress | Phone number to which the message was sent.                                                                 |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

#### SmsSendCDMAParamsType

The [SMSSendParamsType](#) includes an `SmsSendCDMAParamsType` structure for CDMA messages.

```
typedef struct SmsSendCDMAParamsTag
{
    UInt8  messageType;
    TelSmsDateTimeType deferredDate;
    UInt8  priority;
    UInt8  privacy;
    UInt8  alertOnDelivery:1;
    UInt8  manualAckRequest:1;
    UInt8  reserved:6;
    Char*  callbackNumber;
} SmsSendCDMAParamsType, *SmsSendCDMAParamsPtr;
```

### Field Descriptions

|                  |                                                                                                                                           |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| messageType      | The type of the message. This is one of the <a href="#">SMS Message Type Constants</a> constants defined in <code>TelephonyMgr.h</code> . |
| deferredDate     | Not used.                                                                                                                                 |
| priority         | The message priority. This must be one of the <a href="#">SMS Message Urgency Constants</a> .                                             |
| privacy          | The privacy type of the message. This must be one of the <a href="#">SMS Message Privacy Constants</a> .                                  |
| alertOnDelivery  | true if the user is to be alerted upon delivery of this message, and false if not.                                                        |
| manualAckRequest | true if a confirmation is requested from the recipient, and false if not.                                                                 |
| reserved         | Reserved for future use.                                                                                                                  |
| callbackNumber   | Number to which the confirmation should be sent.                                                                                          |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

### SmsSendGSMPParamsType

The [SMSSendParamsType](#) includes an `SmsSendGSMPParamsType` structure for GSM messages.

```
typedef struct SmsSendGSMPParamsTag
{
    UInt16 protocolId;
    Char *serviceCenterNumber;
    Boolean rejectDuplicated;
    Boolean replyPath;
} SmsSendGSMPParamsType, *SmsSendGSMPParamsPtr;
```

## SMS Exchange Library

### SMS Exchange Library Data Structures

---

#### Field Descriptions

|                                  |                                                                                                                                                                                                 |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>protocolId</code>          | Reserved for future use.                                                                                                                                                                        |
| <code>serviceCenterNumber</code> | The message center to be used. If not specified, the service center is set according to the system preferences.                                                                                 |
| <code>rejectDuplicated</code>    | If <code>true</code> , the service center rejects messages that have the same message ID, destination address, and originating address as a previously submitted message.                       |
| <code>replyPath</code>           | If <code>true</code> , the service center that delivers the message is requested to provide information about itself to the recipient so that replies are made through the same service center. |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

#### SMSSendParamsType

The `SMSSendParamsType` structure is used as the data field for the [SmsParamsType](#) structure when the SMS Exchange Library is sending data.

```
typedef struct SmsSendParamsTag
{
    TelSmsDateTimeType validityPeriod;
    Char *destinationAddress;
    UInt8 networkDeliveryRequested:1;
    UInt8 ignoreDefaultValue:1;
    UInt8 reserved:6;
    UInt16 partCount;
    UInt16 lastPart;
    UInt8 converter;
    union
    {
        SmsSendGSMParamsType gsm;
        SmsSendCDMAParamsType cdma;
    }
}
```

```
        SmsSendTDMAParamsType tdma;  
    } protocol;  
} SmsSendParamsType, *SmsSendParamsPtr;
```

### Field Descriptions

|                                       |                                                                                                                                                                                                                                                           |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>validityPeriod</code>           | The amount of time for which the message is valid. See <a href="#">TelSmsDateTimeType</a> . The default is set according to the SMS preferences.                                                                                                          |
| <code>destinationAddress</code>       | A buffer that contains the phone number of the message recipient. If no phone number is supplied, the user is prompted for the phone number.                                                                                                              |
| <code>networkDeliveryRequested</code> | If <code>true</code> , the SMS service center sends a delivery confirmation. The default is set according to the SMS preferences. The SMS Exchange Library disables this field for multipart messages.                                                    |
| <code>ignoreDefaultValue</code>       | If <code>false</code> , the validity period, network delivery requested, and SMS center specified in the preferences are used regardless of the values supplied in this structure. If <code>true</code> , the values supplied in this structure are used. |
| <code>reserved</code>                 | Reserved for future use.                                                                                                                                                                                                                                  |
| <code>partCount</code>                | The number of parts in the message. 0 means that the message is not a multipart message. If NBS is used to send the message, it determines the number of parts.                                                                                           |

|           |                                                                                           |
|-----------|-------------------------------------------------------------------------------------------|
| lastPart  | The last part of a multipart message that was successfully sent.                          |
| converter | The header added to the data to specify how it is converted.                              |
| protocol  | Data specific to the protocol used to send the message. Currently, only GSM is supported. |

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SmsSendTDMAParamsType

The [SMSSendParamsType](#) includes an `SmsSendTDMAParamsType` structure for TDMA messages. This structure is currently the same as the [SmsSendCDMAParamsType](#) structure.

```
typedef SmsSendCDMAParamsType  
    SmsSendTDMAParamsType,  
    *SmsSendTDMAParamsPtr;
```

**Compatibility** This structure is only defined if [4.0 New Feature Set](#) is present.

## SMS Exchange Library Constants

### SMS Control Constants

The SMS control constants are passed as the operation parameter to the [ExgControl](#) function. The `ExgControl` function is a way to communicate directly with the SMS Exchange Library. The following table lists the operation constant, the type of data that should be passed as the `valueP` parameter to [ExgControl](#), and what the SMS Exchange Library does in response.

**Table 84.1 ExgControl operations for SMS library**

| Operation                     | value Data Type                                   | Description                                                                                                                                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| exgLibSmsPrefGetOp            | <a href="#">SmsPrefType</a>                       | Returns a pointer to the SMS Exchange Libraries preferences in <code>valueP</code> , creating the preferences and setting them to the default values if they do not exist.                                                                                                                        |
| exgLibSmsPrefGetDefaultOp     | <a href="#">SmsPrefType</a>                       | Returns the default values for the SMS Exchange Library preferences.                                                                                                                                                                                                                              |
| exgLibSmsPrefSetOp            | <a href="#">SmsPrefType</a>                       | Sets the SMS Exchange Library preferences to the values passed in <code>valueP</code> .                                                                                                                                                                                                           |
| exgLibSmsPrefDisplayOp        | kSmsNetworkAuto or kSmsNetworkGSM.<br>Input only. | Display a form that allows the user to set the SMS preferences.                                                                                                                                                                                                                                   |
| exgLibSmsIncompleteGetCountOp | UInt16. Output only.                              | Get the number of incomplete messages currently stored in the SMS Exchange Library. The library stores message parts as it receives them. When it has received all of the parts, it reassembles the message and delivers it. This operation tells how many messages are currently under assembly. |
| exgLibSmsIncompleteDeleteOp   | UInt16. Input only.                               | Delete the incomplete message with the ID passed in <code>valueP</code> . Pass -1 to delete all incomplete messages.                                                                                                                                                                              |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Data Coding Scheme Constants

The SMS data coding scheme constants describe the coding scheme used for SMS data. These values are used as the `dataCodingScheme` parameter of the [SmsParamsType](#) structure.

| Constant                         | Value | Description                                 |
|----------------------------------|-------|---------------------------------------------|
| <code>kSmsRowDataEncoding</code> | 0     | 8-bit encoding scheme. This is the default. |
| <code>kSmsTextEncoding</code>    | 1     | 7-bit encoding scheme.                      |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Network Type Constants

The SMS network type constants identify the type of network being used for SMS messages. Currently, only the GSM network is supported.

| Constant                     | Value                    | Description                                           |
|------------------------------|--------------------------|-------------------------------------------------------|
| <code>kSmsNetworkAuto</code> | -1                       | The network is set by the phone. This is the default. |
| <code>kSmsNetworkCDMA</code> | <code>kTelNwkCDMA</code> | A CDMA network. Currently not supported.              |
| <code>kSmsNetworkGSM</code>  | <code>kTelNwkGSM</code>  | A GSM network.                                        |
| <code>kSmsNetworkTDMA</code> | <code>kTelNwkTDMA</code> | A TDMA network. Currently not supported.              |
| <code>kSmsNetworkPDC</code>  | <code>kTelNwkPDC</code>  | A PDC network. Currently not supported.               |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

## SMS Message Type Constants

The SMS message type constants identify the type of message being sent. They are used as the `dataType` field of the [SmsParamsType](#) structure.

| <b>Constant</b>    | <b>Value</b> | <b>Description</b>                                                    |
|--------------------|--------------|-----------------------------------------------------------------------|
| kSmsMessageType    | 0            | Standard SMS message of no more than 160 bytes. This is the default.  |
| kSmsIncompleteType | 1            | A part of a multipart SMS message.                                    |
| kSmsReportType     | 2            | A confirmation, indicating that an SMS message was successfully sent. |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

### **SMS Converter Constants**

The SMS converter constants identify the header information added to an SMS message.

| <b>Constant</b>  | <b>Value</b> | <b>Description</b>                                          |
|------------------|--------------|-------------------------------------------------------------|
| kSmsNBSConverter | 0            | An NBS header is added to the message. This is the default. |
| kSmsNoConverter  | 1            | No header is added to the message.                          |

**Compatibility** These constants are only defined if [4.0 New Feature Set](#) is present.

# Personal Data Interchange Library

---

This chapter provides reference material for the Personal Data Interchange (PDI) library, which provides tools for reading and writing vObjects, including vCards and vCals. This chapter discusses the following topics:

- [PDI Library Data Structures](#)
- [PDI Library Constants](#)
- [PDI Library Functions](#)

The header file `PdiLib.h` declares the Personal Data Interchange library API. The header file `PdiConst.h` declares the constants that you use with the PDI library.

For information about how to use the functions and constants described in this chapter, see [Chapter 3, “Personal Data Interchange,”](#) in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## PDI Library Data Structures

This section describes the data structures used with the PDI library functions.

### PdiDictionary

The `PdiDictionary` type is a simple typedef that represents an internal, binary object.

```
typedef UInt8 PdiDictionary;
```

## **PdiReaderType**

The `PdiReaderType` data structure represents a PDI reader object, which you use to read data from an input stream.

```
typedef struct _PdiReader {
    Err                error;
    UInt8              encoding;
    CharEncodingType   charset;
    UInt16             written;
    UInt8              fieldNum;
    UInt16             property;
    UInt16             propertyValueType;
    UInt16             parameter;
    UInt32             parameterPairs[kPDI_ENTRIES_NUMBER];
    UInt16             customFieldNumber;
    void               *appData;
    UInt16             pdiRefNum;
    UInt16             events;
    Char               *groupName;
    Char               *propertyName;
    Char               *parameterName;
    Char               *parameterValue;
    Char               *propertyValue;
    PdiDictionary      *dictionary[2];
} PdiReaderType
```

### **Field Descriptions**

|                       |                                                                          |
|-----------------------|--------------------------------------------------------------------------|
| <code>error</code>    | The most recent error.                                                   |
| <code>encoding</code> | The type of encoding for the property value.                             |
| <code>charset</code>  | The character set of the property value.                                 |
| <code>written</code>  | The number of characters that have currently been written to the buffer. |
| <code>fieldNum</code> | The current field number.                                                |

|                                                                                                         |                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>property</code>                                                                                   | The ID of the current property.                                                                                                                                                          |
| <code>propertyValueType</code>                                                                          | The value type of the current property value.                                                                                                                                            |
| <code>parameter</code>                                                                                  | The ID of the most recently parsed parameter name.                                                                                                                                       |
| <code>parameterPairs</code>                                                                             | An integer array with bits set for each parameter value that has been parsed for the current property value.                                                                             |
| <hr/> <b>NOTE:</b> You must use the <code>PdiParameterPairTest</code> macro to access this field. <hr/> |                                                                                                                                                                                          |
| <code>customFieldNumber</code>                                                                          | The number of the custom field parsed by the reader for the current property. Custom fields are used in the Palm™ Address Book.                                                          |
| <code>appData</code>                                                                                    | Application-dependent data field.                                                                                                                                                        |
| <code>pdiRefNum</code>                                                                                  | The library reference number associated with this reader.                                                                                                                                |
| <code>events</code>                                                                                     | The mask of events handled by the reader in its most recent operation. This is a combination of some number of the event constants described in <a href="#">Reader Event Constants</a> . |
| <code>groupName</code>                                                                                  | The group name for the current property.                                                                                                                                                 |
| <code>propertyName</code>                                                                               | The name of the current property.                                                                                                                                                        |
| <code>parameterName</code>                                                                              | The name of the current parameter.                                                                                                                                                       |
| <code>parameterValue</code>                                                                             | The value of the current parameter.                                                                                                                                                      |

## Personal Data Interchange Library

### *PDI Library Data Structures*

---

|               |                                                                                                                                                                                                                                                                            |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| propertyValue | The current property value string.                                                                                                                                                                                                                                         |
| dictionary    | An array of two dictionary pointers. The dictionary[0] entry is the main dictionary built into the PDI library, and the dictionary[1] entry is an optional, custom dictionary associated with the reader object with a call to <a href="#">PdiDefineReaderDictionary</a> . |

## **PdiWriterType**

The PdiWriterType data structure represents a PDI writer object, which you use to write data to an output stream.

```
typedef struct _PdiWriter {
    void                *appData;
    UInt16              pdiRefNum;
    UInt16              encoding;
    CharEncodingType    charset;
    Err                 error;
    PdiDictionary       *dictionary[2];
} PdiWriterType
```

### **Field Descriptions**

|           |                                                           |
|-----------|-----------------------------------------------------------|
| appData   | Application-dependent data field.                         |
| pdiRefNum | The library reference number associated with this reader. |
| encoding  | The type of encoding for the property value.              |
| charset   | The character set of the property value.                  |

|            |                                                                                                                                                                                                                                                                                                      |
|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| error      | The most recent error.                                                                                                                                                                                                                                                                               |
| dictionary | An array of two dictionary pointers. The <code>dictionary[0]</code> entry is the main dictionary built into the PDI library, and the <code>dictionary[1]</code> entry is an optional, custom dictionary associated with the reader object with a call to <a href="#">PdiDefineReaderDictionary</a> . |

## PDI Library Constants

This section describes the constants used in the PDI library, which include the following constant types:

- [Buffer Management Constants](#)
- [Encoding Type Constants](#)
- [Error Code Constants](#)
- [Parameter Name Constants](#)
- [Parameter Value Constants](#)
- [Property Name Constants](#)
- [Property Type Constants](#)
- [Property Value Field Constants](#)
- [Property Value Format Constants](#)
- [Reader and Writer Options Constants](#)
- [Reader Event Constants](#)
- [Value Type Constants](#)

### Buffer Management Constants

You use the buffer management constants to determine how buffers are managed in the PDI reader.

## Personal Data Interchange Library

### PDI Library Constants

---

| Constant                                | Value               | Description                                                                                                                                                                                                                  |
|-----------------------------------------|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kPdiResizableBuffer</code>        | <code>0xFFFF</code> | Indicates that the buffer can be automatically resized by the PDI library.                                                                                                                                                   |
| <code>kPdiDefaultBufferMaxSize</code>   | <code>0x3FFF</code> | The default maximum buffer size, in bytes. You can change the maximum size of a reader's buffer by calling the <a href="#">PdiDefineResizing</a> function.                                                                   |
| <code>kPdiDefaultBufferDeltaSize</code> | <code>0x0010</code> | The default number of bytes by which the input buffer is grown when the PDI library performs automatic resizing. You can change the delta amount of a reader's buffer by calling <a href="#">PdiDefineResizing</a> function. |

---

## Encoding Type Constants

You use the encoding type constants to specify the type of encoding used in a vObject reader or writer.

| Constant                       | Value                                          | Description                                                                                                                                                                                               |
|--------------------------------|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kPdiASCIIEncoding</code> | <code>0</code>                                 | The vObject is not encoded.                                                                                                                                                                               |
| <code>kPdiQPEncoding</code>    | <code>kPdiPAV_ENCODING_QUOTED_PRINTABLE</code> | The vObject uses the quoted printable encoding.                                                                                                                                                           |
| <code>kPdiB64Encoding</code>   | <code>kPdiPAV_ENCODING_BASE64</code>           | The vObject uses Base 64 encoding. The writer outputs "ENCODING=BASE64."                                                                                                                                  |
| <code>kPdiBEncoding</code>     | <code>kPdiPAV_ENCODING_B</code>                | The vObject uses Base 64 encoding. This is the same as the <code>kPdiB64Encoding</code> value, except that the PDI writer outputs "ENCODING=B."<br><br>This encoding is used with the vCard 3.0 standard. |

---

| <b>Constant</b>    | <b>Value</b> | <b>Description</b>                                |
|--------------------|--------------|---------------------------------------------------|
| kPdiEscapeEncoding | 0x8000       | The vObject uses escapes for special characters.  |
| kPdiNoEncoding     | 0x8001       | The PDI writer does not encode the vObject value. |

---

## **Error Code Constants**

The PDI library functions return the error code constants shown in the following table to indicate their status.

| <b>Constant</b>       | <b>Description</b>                                                                               |
|-----------------------|--------------------------------------------------------------------------------------------------|
| pdiErrRead            | An error occurred while reading from the input stream.                                           |
| pdiErrWrite           | An error occurred while writing to the output stream.                                            |
| pdiErrNoPropertyName  | An attempt was made to write a property value before the property name was written.              |
| pdiErrNoPropertyValue | The application did not write the last property value.                                           |
| pdiErrMoreChars       | The buffer is full. Superfluous characters have been discarded.                                  |
| pdiErrNoMoreFields    | There are no more property fields to read.                                                       |
| pdiErrOpenFailed      | The PDI library could not be opened.                                                             |
| pdiErrCloseFailed     | The PDI library could not be closed. This can occur if another application is using the library. |

---

## Parameter Name Constants

The `PdiConst.h` file defines several parameter name constants that you can use to specify the name of a parameter in functions that use parameter names. The parameter name constants have the following format:

```
kPdiPAN_parameterName
```

where *parameterValue* is replaced by a parameter name.

The following table shows examples of parameter name constants. For a complete list, see the `PdiConst.h` file.

| Constant                      | Description             |
|-------------------------------|-------------------------|
| <code>kPdiPAN_TYPE</code>     | The TYPE parameter.     |
| <code>kPdiPAN_ENCODING</code> | The ENCODING parameter. |
| <code>kPdiPAN_STATUS</code>   | The STATUS parameter.   |

## Parameter Value Constants

The `PdiConst.h` file defines several parameter value constants that you can use to specify the name and value of a parameter in functions that use name and value pairs. The parameter value constants have the following format:

```
kPdiPAV_parameterName_parameterValue
```

where *parameterName* is replaced by a parameter name and *parameterValue* is replaced by a parameter value.

The following table shows examples of parameter value constants. For a complete list, see the `PdiConst.h` file.

| Constant                             | Description                                                   |
|--------------------------------------|---------------------------------------------------------------|
| <code>kPdiPAV_TYPE_TEL</code>        | The parameter name is TYPE and the parameter value is TEL.    |
| <code>kPdiPAV_ENCODING_BASE64</code> | The parameter name is ENCODING and parameter value is BASE64. |

| <b>Constant</b>         | <b>Description</b>                                                |
|-------------------------|-------------------------------------------------------------------|
| kPdiPAV_ENCODING_8BIT   | The parameter name is ENCODING and the parameter value is 8BIT.   |
| kPdiPAV_STATUS_ACCEPTED | The parameter name is STATUS and the parameter value is ACCEPTED. |

## Property Name Constants

The `PdiConst.h` file defines several property name constants that you can use to specify the name of a PDI property in functions that use property names. The property name constants have the following format:

`kPdiPRN_propertyName`

where *propertyName* is replaced by a property name.

The following table shows examples of property name constants. For a complete list, see the `PdiConst.h` file.

| <b>Constant</b>     | <b>Description</b>        |
|---------------------|---------------------------|
| kPdiPRN_ADR         | The ADR property.         |
| kPdiPRN_BDAY        | The BDAY property.        |
| kPdiPRN_BEGIN       | The BEGIN property.       |
| kPdiPRN_BEGIN_VCARD | The BEGIN:VCARD property. |

## Property Type Constants

You use the property type constants to specify the data type of a property.

| <b>Constant</b>     | <b>Value</b> | <b>Description</b>                            |
|---------------------|--------------|-----------------------------------------------|
| kPdiType_URI        | 0            | The data is a uniform resource identifier.    |
| kPdiType_UTC_OFFSET | 1            | The data is an offset from UTC to local time. |

## Personal Data Interchange Library

### PDI Library Constants

---

| Constant             | Value | Description                                       |
|----------------------|-------|---------------------------------------------------|
| kPdiType_RECUR       | 2     | The data is a specification of a recurrence rule. |
| kPdiType_PERIOD      | 3     | The data is a precise period of time.             |
| kPdiType_CAL_ADDRESS | 4     | Calendar user data.                               |
| kPdiType_BINARY      | 5     | Binary data.                                      |
| kPdiType_TEXT        | 6     | Text data.                                        |
| kPdiType_FLOAT       | 7     | Floating-point data.                              |
| kPdiType_DURATION    | 8     | Time duration data.                               |
| kPdiType_DATE_TIME   | 9     | Calendar date and time data.                      |
| kPdiType_DATE        | 10    | Date data.                                        |
| kPdiType_INTEGER     | 11    | Signed integer data.                              |
| kPdiType_TIME        | 12    | Time-of-day data.                                 |

---

### Property Value Field Constants

The `PdiConst.h` file defines several property value field constants that you can use to specify the position of a PDI property value field in functions that use fields. The property value field constants have the following format:

`kPdiPVF_propertyValueField`

where *propertyValueField* is replaced by a property value field name.

The following table shows examples of property name constants. For a complete list, see the `PdiConst.h` file.

| <b>Constant</b>         | <b>Description</b>                                                           |
|-------------------------|------------------------------------------------------------------------------|
| kPdiPVF_ADR_POST_OFFICE | The property value field that stores the post office portion of the address. |
| kPdiPVF_ADR_EXTENDED    | The property value field that stores the extended portion of the address.    |
| kPdiPAN_ADR_COUNTRY     | The property value field that stores the country portion of the address.     |

---

## Property Value Format Constants

Some properties have **structured values**, which are values that contain multiple fields. These fields are typically separated by commas or semicolons in the vObject input or output stream. You use the property value format constants with the [PdiReadPropertyField](#) and [PdiWritePropertyStr](#) functions to specify how to handle fields in a structured value.

| <b>Constant</b> | <b>Value</b> | <b>Description</b>                                                                                                                                                                                |
|-----------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiNoFields    | 0            | There are no fields in the property value; <a href="#">PdiReadPropertyField</a> reads the entire value, or <a href="#">PdiWritePropertyStr</a> specifies that the entire value should be written. |
| kPdiCommaFields | 1            | Fields are separated with comma (“,”) characters; <a href="#">PdiReadPropertyField</a> reads one field, or <a href="#">PdiWritePropertyStr</a> specifies that one field should be written.        |

## Personal Data Interchange Library

### PDI Library Constants

---

| Constant             | Value | Description                                                                                                                                                                                    |
|----------------------|-------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiSemicolonFields  | 2     | Fields are separated with semicolon (“;”) characters; <a href="#">PdiReadPropertyField</a> reads one field, or <a href="#">PdiWritePropertyStr</a> specifies that one field should be written. |
| kPdiDefaultFields    | 4     | The parser decides the property value format, based on the property name.                                                                                                                      |
| kPdiConvertComma     | 8     | Fields are separated with comma characters; <a href="#">PdiReadPropertyField</a> reads the entire value and converts each comma into a newline (“\n”) character.                               |
| kPdiConvertSemicolon | 16    | Fields are separated with semicolon characters; <a href="#">PdiReadPropertyField</a> reads the entire value and converts each semicolon into a newline (“\n”) character.                       |

---

## Reader and Writer Options Constants

You use the reader and writer option constants to control how the PDI reader (parser) reads values from the input stream or to control how the PDI writer (generator) writes values to the output stream.

| <b>Constant</b>                        | <b>Value</b> | <b>Description</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kPdiEnableFolding</code>         | 1            | <p>Enables folding of properties in the output stream.</p> <p><b>Folding</b> is a mechanism for breaking long lines to allow them to be transmitted without change. If you specify this flag, the PDI library folds long lines.</p> <p>Note that folding is not compatible with earlier versions of the Palm OS®.</p> <p>Also note that other encoding formats, including quoted-printable and Base 64, define their own mechanisms for splitting long lines.</p> |
| <code>kPdiEnableQuotedPrintable</code> | 2            | <p>Enables quoted-printable encoding in the output stream and makes it the default encoding.</p> <p>This is an encoding format for non-ASCII values. You must have this enabled for compatibility with earlier versions of the Palm OS.</p> <p>If you do not specify this option, the default encoding is Base 64.</p>                                                                                                                                            |

## Personal Data Interchange Library

### PDI Library Constants

---

| Constant                                | Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kPdiEscapeMultiFieldValues</code> | 4     | <p>For compatibility with earlier versions of the Palm OS.</p> <p>You must enable this for compatibility with earlier versions of the Palm OS. However, some non-Palm PDI software does not support this format.</p> <p>For more information about compatibility with earlier versions of the Palm OS, see <a href="#">Format Compatibility</a> in the <i>Palm OS Programmer's Companion</i>, vol. II, <i>Communications</i>.</p> |
| <code>kPdiPalmCompatibility</code>      | 6     | <p>This is a combination of <code>kPdiEnableQuotedPrintable</code>   <code>kPdiEscapeMultiFieldValues</code>.</p> <p>It forces the PDI writer to generate output that is compatible with earlier versions of the Palm OS.</p>                                                                                                                                                                                                     |
| <code>kPdiEnableB</code>                | 8     | <p>Enables base 64 encoding in the output stream, and tells the PDI writer to output "ENCODING=B" instead of "ENCODING=BASE64" when encoding a value with Base 64.</p> <p>Note: the vCard 3.0 standard has replaced the earlier ENCODING=BASE64 with ENCODING=B. The meaning is the same.</p>                                                                                                                                     |
| <code>kPdiOpenParser</code>             | 8     | <p>Specifies that the PDI reader is open to all formats, including Palm and others.</p>                                                                                                                                                                                                                                                                                                                                           |

---

## Reader Event Constants

The PDI reader event constants specify the events that the reader has handled during the current read operation. The event values are combined together and stored in the `events` field of the PDI reader object. You can use them to test whether the reader handled a certain event.

| <b>Constant</b>                              | <b>Value</b> | <b>Description</b>                                                                        |
|----------------------------------------------|--------------|-------------------------------------------------------------------------------------------|
| <code>kPdiEOFEventMask</code>                | 1            | End of file was reached.                                                                  |
| <code>kPdiGroupNameEventMask</code>          | 2            | A group name was found.                                                                   |
| <code>kPdiPropertyNameEventMask</code>       | 4            | A property name was found.                                                                |
| <code>kPdiParameterNameEventMask</code>      | 8            | A parameter name was found.                                                               |
| <code>kPdiParameterValueEventMask</code>     | 16           | A parameter value was found.                                                              |
| <code>kPdiPropertyDefinedEventMask</code>    | 32           | A property definition was found; this implies that the ":" separator character was found. |
| <code>kPdiPropertyValueEventMask</code>      | 64           | An entire property value was found                                                        |
| <code>kPdiPropertyValueFieldEventMask</code> | 128          | A value field was found; this implies that the ";" separator character was found.         |
| <code>kPdiPropertyValueItemEventMask</code>  | 256          | A value item was found; this implies that the "," separator character was found.          |

## Personal Data Interchange Library

### PDI Library Constants

---

| Constant                            | Value | Description                                                                                        |
|-------------------------------------|-------|----------------------------------------------------------------------------------------------------|
| kPdiPropertyValueMoreCharsEventMask | 512   | The buffer that you provided was not large enough. The superfluous characters have been discarded. |
| kPdiBeginObjectEventMask            | 1024  | The object begin indicator BEGIN was reached.                                                      |
| kPdiEndObjectEventMask              | 2048  | The object end indicator END was reached.                                                          |

---

### Value Type Constants

You can use the following constants to specify data typing information for the [PdiWritePropertyBinaryValue](#), [PdiWritePropertyFields](#), and [PdiWritePropertyValue](#) functions.

| Constant           | Value | Description                                                                                                                                                                                     |
|--------------------|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| kPdiWriteData      | 0     | The value is data. The PDI writer does not compute a character set. You can use this for binary data or pure ASCII data.                                                                        |
| kPdiWriteText      | 8     | The value is text data. The PDI writer parses the data character by character to compute the correct charset and character encoding for the data.                                               |
| kPdiWriteMultiline | 16    | Explicitly specifies that the value contains special characters, such as newlines, and must be encoded. If this flag is not specified, the encoding is determined by the applied character set. |

---

## PDI Library Functions

### PdiDefineReaderDictionary

- Purpose** Installs a new custom dictionary for use with a PDI reader object.
- Declared In** `PdiLib.h`
- Prototype**  
`PdiDictionary *PdiDefineReaderDictionary`  
`(UInt16 libRefnum, PdiReaderType *ioReader,`  
`PdiDictionary *dictionary,`  
`Boolean disableMainDictionary)`
- Parameters**
- > `libRefnum` The PDI library reference number.
  - > `ioReader` The PDI reader object with which to associate the dictionary. This object must have previously been created by a call to the [PdiReaderNew](#) function.
  - > `dictionary` A pointer to a dictionary object that was created by the . The dictionary object is an array of binary data.
  - > `disableMainDictionary`  
If `true`, the main reader dictionary is disabled, and only this new dictionary is searched for terms; if `false`, the new dictionary supplements the main dictionary.
- Result** Returns a pointer to the previously installed custom dictionary, or `NULL` if there was not a previously installed custom dictionary.
- Comments** This function installs a dictionary for use with the `ioReader` object. The dictionary contains the syntax for extensions or replacements of the PDI properties about which the PDI reader knows. The reader knows about properties specified in one of the vObject standards, including the vCard or vCal standards.
- You can uninstall the current custom dictionary by specifying `NULL` as the value of the `dictionary` parameter,

Note that the dictionary must have previously been compiled by the dictionary tool. For more information, review the PDI sample code, which you can find on the Palm Developer's Knowledge Base at <http://www.palmos.com/dev/tech/kb>.

## PdiDefineResizing

**Purpose** Defines the sizing information to use when automatically resizing a buffer. PDI reader objects read information from the input stream into a buffer and automatically adjust the buffer size as required.

**Declared In** PdiLib.h

**Prototype** Err PdiDefineResizing(UInt16 libRefnum,  
PdiReaderType \*ioReader, UInt16 deltaSize,  
UInt16 maxSize)

**Parameters**

- > libRefnum The PDI library reference number.
- > ioReader The PDI reader object, which was created by a previous call to the [PdiReaderNew](#) function.
- > deltaSize The number of bytes by which to grow the buffer when it needs resizing.
- > maxSize The maximum allowable size for the buffer.

**Result** Returns `errNone` if successful, and an error code if not successful.

**Comments** This function redefines the values to use when resizing a buffer. It does not perform any other actions.

The resizing values are used if your reader runs out of buffer space when storing input data during the processing of a property value. If possible, the reader resizes its internal buffer, using the values that you supply in this function.

The default resizing values apply if you do not call this function. The default values are:

|                            |        |
|----------------------------|--------|
| kPdiDefaultBufferDeltaSize | 0x0010 |
| kPdiDefaultBufferMaxSize   | 0x3FFF |

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## **PdiDefineWriterDictionary**

**Purpose**            Installs a new custom dictionary for use with a PDI writer object.

**Declared In**     PdiLib.h

**Prototype**       PdiDictionary \*PdiDefineWriterDictionary  
                  (UInt16 libRefnum, PdiWriterType \*ioWriter,  
                  PdiDictionary \*dictionary,  
                  Boolean disableMainDictionary)

**Parameters**

- > libRefnum        The PDI library reference number.
- > ioWriter         The PDI writer object with which to associate the dictionary. This object must have previously been created by a call to the [PdiWriterNew](#) function.
- > dictionary      A pointer to a dictionary object that was created by the . The dictionary object is an array of binary data.
- > disableMainDictionary  
                      If true, the main dictionary is disabled, and only this new dictionary is searched for terms; if false, the new dictionary supplements the main dictionary.

**Result**            Returns a pointer to the previously installed custom dictionary, or NULL if there was not a previously installed custom dictionary.

**Comments**        This function installs a dictionary for use with the ioWriter object. The dictionary contains the syntax for extensions or replacements of the PDI properties about which the PDI writer knows. The writer knows about properties specified in one of the vObject standards, including the vCard or vCal standards.

You can uninstall the current custom dictionary by specifying NULL as the value of the dictionary parameter,

## Personal Data Interchange Library

### PDI Library Functions

---

Note that the dictionary must have previously been compiled by the dictionary tool. For more information, review the PDI sample code, which you can find on the Palm Developer's Knowledge Base at <http://www.palmos.com/dev/tech/kb/>.

## PdiEnterObject

- Purpose** Tells the PDI library to enter into a recursively-defined object.
- Declared In** PdiLib.h
- Prototype**

```
Err PdiEnterObject (UInt16 libRefnum,
PdiReaderType *ioReader)
```
- Parameters**
- > libRefnum The PDI library reference number.
  - > ioReader The PDI reader object, which was created by a previous call to the [PdiReaderNew](#) function.
- Result** Returns `errNone` if successful, and an error code if not successful.
- Comments** Some vObjects recursively define other vObjects. Your application can choose whether or not to enter and parse the recursively defined objects.
- If you want to parse the nested object definition, you need to call this function; otherwise, all of the properties of the nested object are skipped when the next call is made to the [PdiReadProperty](#) or [PdiReadPropertyName](#) functions.
- Call this function after a `BEGIN_VObject` statement of the nested object has been parsed.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **PdiLibClose**

|                      |                                                                                                                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Close the PDI library after your application has finished with it.                                                                                                                                                                           |
| <b>Declared In</b>   | <code>PdiLib.h</code>                                                                                                                                                                                                                        |
| <b>Prototype</b>     | <code>Err PdiLibClose(UInt16 libRefnum)</code>                                                                                                                                                                                               |
| <b>Parameters</b>    | <code>-&gt; libRefnum</code> The PDI library reference number.                                                                                                                                                                               |
| <b>Result</b>        | Returns 0 if no other application uses the library. You may need to call <a href="#">SysLibRemove</a> to remove the PDI library from the system library table.<br>Returns <code>pdiErrCloseFailed</code> if the library could not be closed. |
| <b>Comments</b>      | You should call this function after your application has finished with the PDI library, to allow the resources to be recovered.                                                                                                              |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                          |
| <b>See Also</b>      | <a href="#">PdiLibOpen</a>                                                                                                                                                                                                                   |

## **PdiLibOpen**

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Purpose</b>     | Opens the PDI library for use by your application.                               |
| <b>Declared In</b> | <code>PdiLib.h</code>                                                            |
| <b>Prototype</b>   | <code>Err PdiLibOpen(UInt16 libRefnum)</code>                                    |
| <b>Parameters</b>  | <code>-&gt; libRefnum</code> The PDI library reference number.                   |
| <b>Result</b>      | Returns <code>errNone</code> if successful, and an error code if not successful. |
| <b>Comments</b>    | You must call this function before calling any of the other PDI functions.       |

## Personal Data Interchange Library

### PDI Library Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiLibClose](#)

## PdiParameterPairTest

**Purpose** A macro that determines if the reader has already parsed the specified parameter value or name-value pair.

**Declared In** PdiLib.h

**Prototype** PdiParameterPairTest (reader, pair)

**Parameters**

|           |                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------|
| -> reader | The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function. |
| -> pair   | The ID of the parameter. This must be one of the <a href="#">Parameter Value Constants</a> .              |

**Result** Returns `true` if the specified parameter name-value pair has been parsed for the current property, and `false` if not.

**Comments** Some vObject generators do not specify the parameter name if the name is considered evident from the context. This means that both of the following constructs are considered proper:

```
Name=Value  
Value
```

The `PdiParameterPairTest` macro returns `true` if the value has been parsed in either format. For example,

```
PdiParameterPairTest (reader, kPdiPAV_TYPE_WORK)
```

returns `true` for either of the following:

```
Type=WORK  
WORK
```

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **PdiReaderDelete**

|                      |                                                                                                                                                                                                                                                               |              |                                   |              |                                                                                                                        |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|-----------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Delete a PDI reader object that is associated with the specified library number.                                                                                                                                                                              |              |                                   |              |                                                                                                                        |
| <b>Declared In</b>   | PdiLib.h                                                                                                                                                                                                                                                      |              |                                   |              |                                                                                                                        |
| <b>Prototype</b>     | <pre>void PdiReaderDelete(UInt16 libRefnum,<br/>PdiReaderType **ioReader)</pre>                                                                                                                                                                               |              |                                   |              |                                                                                                                        |
| <b>Parameters</b>    | <table><tr><td>-&gt; libRefnum</td><td>The PDI library reference number.</td></tr><tr><td>&lt;-&gt; ioReader</td><td>A pointer to the PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function.</td></tr></table> | -> libRefnum | The PDI library reference number. | <-> ioReader | A pointer to the PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function. |
| -> libRefnum         | The PDI library reference number.                                                                                                                                                                                                                             |              |                                   |              |                                                                                                                        |
| <-> ioReader         | A pointer to the PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function.                                                                                                                                        |              |                                   |              |                                                                                                                        |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                              |              |                                   |              |                                                                                                                        |
| <b>Comments</b>      | This function deletes the UDARreader object associated with the reader object and frees the memory that was allocated for the reader object. The ioReader parameter is set to NULL.                                                                           |              |                                   |              |                                                                                                                        |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                           |              |                                   |              |                                                                                                                        |
| <b>See Also</b>      | <a href="#">PdiReaderNew</a>                                                                                                                                                                                                                                  |              |                                   |              |                                                                                                                        |

## **PdiReaderNew**

|                    |                                                                                                     |              |                                   |
|--------------------|-----------------------------------------------------------------------------------------------------|--------------|-----------------------------------|
| <b>Purpose</b>     | Create and initialize a new PDI reader object for use with the specified PDI library number.        |              |                                   |
| <b>Declared In</b> | PdiLib.h                                                                                            |              |                                   |
| <b>Prototype</b>   | <pre>PdiReaderType *PdiReaderNew(UInt16 libRefnum,<br/>UDARreaderType *input, UInt16 version)</pre> |              |                                   |
| <b>Parameters</b>  | <table><tr><td>-&gt; libRefnum</td><td>The PDI library reference number.</td></tr></table>          | -> libRefnum | The PDI library reference number. |
| -> libRefnum       | The PDI library reference number.                                                                   |              |                                   |

## Personal Data Interchange Library

### PDI Library Functions

---

- > `input`      The Unified Data Access (UDA) input object associated with the reader.
- > `version`      Options to control the parsing behavior of the reader. You can use a combination of the [Reader and Writer Options Constants](#).

**Result**      Returns a pointer to the new PDI reader object. Returns NULL if the reader cannot be created.

**Comments**      The current implementation of the `PdiReaderNew` function does not make use of the `optionFlags` settings because the reader knows how to adapt itself to all of the supported formats. The options will be used in future versions.

The `input` value is a UDA object for reading data from an input stream that can be connected to various data sources. For example, you can use a `UDAExchangeReader` to read data from the Exchange Manager, and you can use a `UDAStringReader` to read data from a string. For more information about the UDA Manager, see [Chapter 86, "Unified Data Access Manager."](#)

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

**See Also**      [PdiReaderDelete](#), [PdiWriterNew](#)

## PdiReadParameter

**Purpose**      Read a single parameter name and its value from an input stream.

**Declared In**      `PdiLib.h`

**Prototype**      `Err PdiReadParameter(UInt16 libRefnum,  
PdiReaderType *ioReader)`

**Parameters**      -> `libRefnum`      The PDI library reference number.

**Result**

|               |                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------|
| -> ioReader   | The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function. |
| 0             | The parameter and its value were read successfully.                                                       |
| kPdiReadError | The parameter and its value could not be successfully read from the input stream.                         |

This function initializes the `parameterName` and `parameter` fields of the `ioReader` object.

This function sets the appropriate bits in the reader's `parameterValues` field if the parameter name is recognized.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiReaderNew](#), [PdiReadPropertyField](#), [PdiReadPropertyName](#)

## PdiReadProperty

**Purpose** Read the next property and its parameters from the input stream.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiReadProperty(UInt16 libRefnum, PdiReaderType *ioReader)`

**Parameters**

|              |                                                                                                           |
|--------------|-----------------------------------------------------------------------------------------------------------|
| -> libRefnum | The PDI library reference number.                                                                         |
| -> ioReader  | The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function. |

**Result** Returns `errNone` if successful. Returns `kPdiReadError` if an error occurs.

**Comments** The `PdiReadProperty` function reads a property name and its parameters, by reading until it encounters the PDI ":" separator character.

## Personal Data Interchange Library

### PDI Library Functions

---

This function looks each name up in the properties dictionary, and sets the appropriate bit in the `ioReader` object structure to indicate that property-parameter pair has been read. The properties dictionary stores information about properties that are considered well known, as described in [The PDI Library Properties Dictionary](#) in [Chapter 3, "Personal Data Interchange,"](#) in *Palm OS Programmer's Companion*, vol. II, *Communications*.

To read a property, you call `PdiReadProperty`, followed by a call or calls to the [PdiReadPropertyField](#) function to read the property value. For more information, see [Reading Properties](#) in [Chapter 3, "Personal Data Interchange,"](#) in *Palm OS Programmer's Companion*, vol. II, *Communications*.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiReaderNew](#), [PdiReadPropertyField](#),  
[PdiReadPropertyName](#), [PdiReadParameter](#)

## PdiReadPropertyField

**Purpose** Read one field of a property value. The property value can be structured to contain multiple fields that are separated by commas or semicolons.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiReadPropertyField(UInt16 libRefnum,  
PdiReaderType *ioReader, Char **bufferPP,  
UInt16 bufferSize, UInt16 readMode)`

**Parameters**

|                           |                                                                                                                                                |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>libRefnum</code> | The PDI library reference number.                                                                                                              |
| -> <code>ioReader</code>  | The PDI reader object, which was created by a previous call to the <a href="#">PdiReaderNew</a> function.                                      |
| <-> <code>bufferPP</code> | A pointer to a pointer to the buffer into which the field characters are stored. Set this value to NULL to allow the PDI library to manage it. |

Note that the PDI library may need to resize the buffer; thus, the value of this parameter might change.

-> `bufferSize` The size, in bytes, of the input buffer for reading the field.

You can use the `PdiResizableBuffer` constant to specify that the PDI Library can automatically resize the buffer as required.

If you do not specify the `PdiResizableBuffer` value, then the PDI library assumes that `buffer` cannot be moved, and that its size is fixed.

-> `readMode` The format of the fields in the property value. Use one of the [Property Value Format Constants](#).

**Result** 0 The field was read successfully.

`kPdiNoMoreFieldsError`

There are no more fields to read because the entire value has already been read.

`kPdiMoreCharsError`

The buffer is not large enough to store the entire field.

**Comments** The value returned in the `buffer` is terminated with the “\0” character.

If the field is an empty string, the buffer is erased from memory, and the value of `buffer` is set to `NULL`.

If you specify `kPdiResizableBuffer` for the value of the `bufferSize` parameter, and the buffer needs more space, `PdiReadPropertyField` resizes the buffer for you, which may cause the value of `buffer` to be modified.

This function initializes the `propertyValue` and `fieldNum` fields of the `ioReader` object.

To read a property, you usually call the [PdiReadProperty](#) function, followed by a call or calls to `PdiReadPropertyField` to

## Personal Data Interchange Library

### PDI Library Functions

---

read the property value. For more information, see [Reading Properties](#) in [Chapter 3, "Personal Data Interchange,"](#) in *Palm OS Programmer's Companion*, vol. II, *Communications*.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiReaderNew](#), [PdiReadProperty](#), [PdiReadPropertyName](#), [PdiReadParameter](#)

## PdiReadPropertyName

**Purpose** Read a property name from an input stream. Use this function when you want to parse and process each parameter individually.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiReadPropertyName(UInt16 libRefnum, PdiReaderType *ioReader)`

**Parameters**

- > `libRefnum` The PDI library reference number.
- > `ioReader` The PDI reader object, which was created by a previous call to the [PdiReaderNew](#) function.

**Result** Returns `errNone` if successful, and an error code if not successful.

**Comments** The `PdiReadProperty` function reads a property name only, reading until it encounters the PDI ":" separator character, or until it encounters the first parameter "," separator character.

This function initializes the `property` and `propertyName` fields of the `ioReader` object.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiReaderNew](#), [PdiReadPropertyField](#), [PdiReadProperty](#), [PdiReadParameter](#)

| <b>Result</b>        | Returns errNone if successful, and an error code if not successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |              |                                   |             |                                                                                                           |            |                                                                                                                                                                                                                                |
| <b>Comments</b>      | <p>This function tells ioWriter to use the specified charset for the next property value that it writes, rather than computing a character set for that value.</p> <p>You can determine the current character setting by examining the charset field of your PDI writer object.</p>                                                                                                                                                                                                                                     |              |                                   |             |                                                                                                           |            |                                                                                                                                                                                                                                |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |              |                                   |             |                                                                                                           |            |                                                                                                                                                                                                                                |
| <b>See Also</b>      | <a href="#">PdiSetEncoding</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |              |                                   |             |                                                                                                           |            |                                                                                                                                                                                                                                |

### PdiSetEncoding

- Purpose** Force the encoding of the current property value.
- Declared In** PdiLib.h
- Prototype** `Err PdiSetEncoding(UInt16 libRefnum, PdiWriterType *ioWriter, UInt16 encoding)`
- Parameters**
- > libRefnum The PDI library reference number.
  - > ioReader The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
  - > encoding The encoding to apply to the property value. This must be one of the [Encoding Type Constants](#).
- Result** Returns `errNone` if successful, and an error code if not successful.
- Comments** This function changes the encoding for the property value to the specified encoding value  
You can determine the current encoding setting by examining the encoding field of your PDI writer object.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [PdiSetCharset](#)

### PdiWriteBeginObject

- Purpose** Writes a vObject begin tag to an output stream.
- Declared In** PdiLib.h
- Prototype** `Err PdiWriteBeginObject(UInt16 libRefnum, PdiWriterType *ioWriter, UInt16 objectNameID)`
- Parameters**
- > libRefnum The PDI library reference number.

-> ioWriter      The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.

-> objectNameID      The object name ID. This must be one of the [Property Name Constants](#) that begins an object, including the following:

- kPdiPRN\_BEGIN\_VCAL
- kPdiPRN\_BEGIN\_VCAL
- kPdiPRN\_BEGIN\_VCARD
- kPdiPRN\_BEGIN\_VEVENT
- kPdiPRN\_BEGIN\_VFREEBUSY
- kPdiPRN\_BEGIN\_VJOURNAL
- kPdiPRN\_BEGIN\_VTIMEZONE
- kPdiPRN\_BEGIN\_VTODO

**Result**      Returns `errNone` if successful, and an error code if not successful.

**Comments**      Call this function to begin writing a `vObject` to the output stream. It writes a begin tag such as "BEGIN:VCARD" to the output stream.

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

**See Also**      [PdiWriteEndObject](#), [PdiWriteProperty](#)

## **PdiWriteEndObject**

**Purpose**      Writes a `vObject` end tag to an output stream.

**Declared In**      `PdiLib.h`

**Prototype**      `Err PdiWriteEndObject (UInt16 libRefnum, PdiWriterType *ioWriter, UInt16 objectNameID)`

**Parameters**      -> `libRefnum`      The PDI library reference number.

## Personal Data Interchange Library

### PDI Library Functions

---

-> ioWriter      The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.

-> objectNameID  
The object name ID. This must be one of the [Property Name Constants](#) that ends an object, including the following:

- kPdiPRN\_END\_VCAL
- kPdiPRN\_END\_VCAL
- kPdiPRN\_END\_VCARD
- kPdiPRN\_END\_VEVENT
- kPdiPRN\_END\_VFREEBUSY
- kPdiPRN\_END\_VJOURNAL
- kPdiPRN\_END\_VTIMEZONE
- kPdiPRN\_END\_VTODO

**Result**      Returns `errNone` if successful, and an error code if not successful.

**Comments**    Call this function to finish writing a `vObject` to the output stream. It writes a end tag such as "END:VCARD" to the output stream.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**      [PdiWriteBeginObject](#), [PdiWriteProperty](#)

## PdiWriteParameter

**Purpose**        Write a parameter, and optionally its name, to an output stream.

**Declared In**    `PdiLib.h`

**Prototype**     `Err PdiWriteParameter(UInt16 libRefnum,  
PdiWriterType *ioWriter, UInt16 parameter,  
Boolean parameterName)`

**Parameters**    -> `libRefnum`      The PDI library reference number.

- > `ioWriter`      The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
- > `parameter`      The ID of the parameter. This must be one of the [Parameter Value Constants](#).
- > `parameterName`  
If this is `true`, the parameter name, followed by the "=" symbol, followed by the parameter value is written to the output stream.  
  
If this is `false`, only the parameter value is written to the output stream.

**Result**      Returns `errNone` if successful, and an error code if not successful.

**Comments**      Use this function to write a parameter to the output stream. To write a property, you usually call the [PdiWriteProperty](#) function, followed by calls to `PdiWriteParameter` to write any parameters, followed by a call to the [PdiWritePropertyValue](#) function to write the property value. For more information, see [Writing Properties](#) in [Chapter 3, "Personal Data Interchange,"](#) in *Palm OS Programmer's Companion*, vol. II, *Communications*.

You can use the `parameterName` argument to specify that you want the parameter name written as well as the parameter value. For example, the following table shows what is written if the value of `parameter` is `kPdiPAV_TYPE_HOME`.

| Value of <code>parameterName</code> | Data written to output stream |
|-------------------------------------|-------------------------------|
| <code>true</code>                   | TYPE=HOME                     |
| <code>false</code>                  | HOME                          |

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

**See Also**      [PdiWriteProperty](#), [PdiWritePropertyValue](#), [PdiWritePropertyFields](#), [PdiWritePropertyStr](#), [PdiWriteParameterStr](#)

### PdiWriteParameterStr

- Purpose** Write a parameter name and the parameter value to an output stream.
- Declared In** PdiLib.h
- Prototype**  
`Err PdiWriteParameterStr(UInt16 libRefnum,  
PdiWriterType *ioWriter,  
const Char *parameterName,  
const Char *parameterValue)`
- Parameters**
- > libRefnum The PDI library reference number.
  - > ioWriter The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
  - > parameterName  
The name of the parameter. If the value of this is the empty string or NULL, only the parameter value is written.
  - > parameterValue  
The parameter value string.
- Result** Returns `errNone` if successful, and an error code if not successful.
- Comments** This function writes the parameter name, followed by the “=” symbol, followed by the parameter value, to the output stream. If `parameterName` is NULL, or if its value is the empty string, just the parameter value is written.
- This function is similar to the [PdiWriteParameter](#) function. The difference is that `PdiWriteParameterStr` takes the name and value of the parameter as strings, while `PdiWriteParameter` takes them as ID constants.

### **PdiWritePropertyBinaryValue**

**Purpose** Write a binary property value to an output stream.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiWritePropertyBinaryValue(UInt16 libRefnum, PdiWriterType *ioWriter, const Char *buffer, UInt16 size, UInt16 options)`

**Parameters**

- > `libRefnum` The PDI library reference number.
- > `ioWriter` The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
- > `buffer` A buffer that contains the binary data.
- > `size` The number of bytes of data to write from the buffer.
- > `options` The data type. This must be a combination of one or more of the [Value Type Constants](#).

**Result** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function to write a binary data property value, such as a sound or an image.

This function encodes the data when it is written. The character set that gets applied to the data is not computed by this function; however, you can call the [PdiSetCharset](#) function to set the character set.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty](#), [PdiWritePropertyFields](#), [PdiWritePropertyValue](#)

## PdiWritePropertyFields

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |              |                                   |             |                                                                                                           |           |                                                                                                     |                |                                           |            |                                                                                                        |

### PdiWritePropertyStr

- Purpose** Writes the name of a property to the output stream, and specifies the property value's structure for subsequent write operations.
- Declared In** PdiLib.h
- Prototype**  
`Err PdiWritePropertyStr(UInt16 libRefnum,  
PdiWriterType *ioWriter,  
const Char *propertyName, UInt8 writeMode,  
UInt8 requiredFields)`
- Parameters**
- > libRefnum The PDI library reference number.
  - > ioWriter The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
  - > propertyName The name of the property to write.
  - > writeMode The format of the fields in the property value. Use one of the following [Property Value Format Constants](#):
    - kPdiNoFields
    - kPdiCommaFields
    - kPdiSemicolonFields
  - > requiredFields The number of required fields for the value. This is usually set to 1.
- Result** Returns `errNone` if successful, and an error code if not successful.
- Comments** Use this function when you are writing a property that is not in the dictionary, or when you are writing a property that uses value formatting that differs from the standard formatting stored in the dictionary for the property name.
- This function writes the property name to the output stream, and then establishes the structure of the property's value, including the number of required fields and the separator character for those

fields. After calling this function, the next call to the [PdiWritePropertyValue](#) or [PdiWritePropertyFields](#) functions correctly writes the property value.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty](#), [PdiWritePropertyValue](#), [PdiWritePropertyFields](#), [PdiWriteParameter](#)

## **PdiWritePropertyValue**

**Purpose** Write a string to the output stream as the entire value of a property.

**Declared In** `PdiLib.h`

**Prototype** `Err PdiWritePropertyValue(UInt16 libRefnum, PdiWriterType *ioWriter, Char *buffer, UInt16 options)`

**Parameters**

- > `libRefnum` The PDI library reference number.
- > `ioWriter` The PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
- > `buffer` The input buffer that contains the string to be written.
- > `options` The data type. This must be a combination of one or more of the [Value Type Constants](#).

**Result** Returns `errNone` if successful, and an error code if not successful.

**Comments** Use this function to write a property value that contains a single field.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [PdiWriteProperty](#), [PdiWritePropertyFields](#), [PdiWriteParameter](#), [PdiWritePropertyBinaryValue](#)

### PdiWriterDelete

- Purpose** Delete a PDI output stream object.
- Declared In** PdiLib.h
- Prototype**  
`void PdiWriterDelete(UInt16 libRefnum,  
PdiWriterType **ioWriter)`
- Parameters**
- > libRefnum The PDI library reference number.
  - <-> ioWriter A pointer to the PDI writer object, which was created by a previous call to the [PdiWriterNew](#) function.
- Result** Returns nothing.
- Comments** This function frees the memory that was allocated for the writer object. The ioWriter parameter is set to NULL.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [PdiWriterNew](#)

### PdiWriterNew

- Purpose** Initializes a new PDI writer object for use with the specified library number.
- Declared In** PdiLib.h
- Prototype**  
`PdiWriterType *PdiWriterNew(UInt16 libRefnum,  
UDAWriterType *output, UInt16 version)`
- Parameters**
- > libRefnum The PDI library reference number.
  - > output The Unified Data Access (UDA) output object associated with the writer.

-> version      Options to control the behavior of the writer.  
You can use a combination of the [Reader and  
Writer Options Constants](#).

**Result**      Returns a pointer to the new PDI writer object. Returns NULL if the reader cannot be created.

**Comments**      The media pointer is copied into a field in the writer object; thus, you do not need to retain your copy.

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

# Unified Data Access Manager

---

This chapter provides reference material for the Unified Data Access (UDA) Manager, which provides a mechanism for abstracting read and write access to different kinds of source and destination media, including memory and the Exchange Manager.

The Personal Data Interchange (PDI) reader and writer objects use UDA objects, and you must create UDA objects to use the PDI functions.

This chapter discusses the following topics:

- [UDA Manager Data Structures](#)
- [UDA Manager Constants](#)
- [UDA Manager Functions](#)
- [UDA Object Creation Functions](#)

The header file `UDAMgr.h` declares the Unified Data Access Manager API.

You use the UDA Manager in conjunction with the PDI library. For more information about the PDI library, see [Chapter 85, “Personal Data Interchange Library.”](#)

[Chapter 3, “Personal Data Interchange,”](#) in the *Palm OS Programmer’s Companion*, vol. II, *Communications*, provides examples of using the UDA functions with the PDI library.

## UDA Manager Data Structures

### UDABufferSize

The `UDABufferSize` type is a simple typedef that defines the size of buffers used with UDA read functions.

## Unified Data Access Manager

### UDA Manager Data Structures

---

```
typedef UInt16 UDABufferSize
```

## UDAObjectType

The UDAObjectType is the base class for all UDA objects, and defines the common properties of all of the objects.

```
typedef struct UDAObjectTag {
    UInt16                optionFlags;
    UDADeleteFunction     deleteF;
    UDAControlFunction    controlF;
} UDAObjectType
```

### Field Descriptions

|             |                                                                                                            |
|-------------|------------------------------------------------------------------------------------------------------------|
| optionFlags | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> . |
| deleteF     | The delete function associated with this UDA object.                                                       |
| controlF    | The control function associated with this UDA object.                                                      |

## UDAFilterType

The UDAFilterType represents UDA Filters, which take input from a UDA Reader or UDA Filter, perform some encoding or decoding operation, and output the data to a memory buffer.

```
typedef struct UDAFilterTag {
    UInt16                optionFlags;
    UDADeleteFunction     deleteF;
    UDAControlFunction    controlF;
    UDAReadFunction       readF;
    UDAReaderType*        upperReader;
} UDAFilterType
```

### Field Descriptions

|                          |                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------|
| <code>optionFlags</code> | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> .              |
| <code>deleteF</code>     | The delete function associated with this UDA object.                                                                    |
| <code>controlF</code>    | The control function associated with this UDA object.                                                                   |
| <code>readF</code>       | The read function associated with this UDA object.                                                                      |
| <code>upperReader</code> | The <a href="#">UDAREaderType</a> or <a href="#">UDAFilterType</a> object that reads the data that this object outputs. |

### UDAREaderType

The `UDAREaderType` represents UDA Readers, which read input from a medium.

```
typedef struct UDAREaderTag {
    UInt16          optionFlags;
    UDADeleteFunction deleteF;
    UDAControlFunction controlF;
    UDAREadFunction readF;
} UDAREaderType
```

### Field Descriptions

|                          |                                                                                                            |
|--------------------------|------------------------------------------------------------------------------------------------------------|
| <code>optionFlags</code> | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> . |
| <code>deleteF</code>     | The delete function associated with this UDA object.                                                       |

## Unified Data Access Manager

### UDA Manager Data Structures

---

|                       |                                                       |
|-----------------------|-------------------------------------------------------|
| <code>controlF</code> | The control function associated with this UDA object. |
| <code>readF</code>    | The read function associated with this UDA object.    |

## UDAWriterType

The `UDAWriterType` represents UDA Writers, which take data from a UDA Reader or UDA Filter and write the data to an output medium.

```
typedef struct UDAWriterTag {
    UInt16          optionFlags;
    UDADeleteFunction deleteF;
    UDAControlFunction controlF;
    UDAWriteFunction initiateWriteF;
    UDAFlushFunction flushF;
    UDAReaderType*  upperReader;
} UDAWriterType
```

### Field Descriptions

|                             |                                                                                                            |
|-----------------------------|------------------------------------------------------------------------------------------------------------|
| <code>optionFlags</code>    | Options for the object. This is a combination of values described in <a href="#">Object Option Flags</a> . |
| <code>deleteF</code>        | The delete function associated with this UDA object.                                                       |
| <code>controlF</code>       | The control function associated with this UDA object.                                                      |
| <code>initiateWriteF</code> | The write function associated with this UDA object.                                                        |
| <code>flushF</code>         | The flush function associated with this UDA object.                                                        |
| <code>upperReader</code>    | The <a href="#">UDARedReaderType</a> object that reads the data that this object writes.                   |

## UDA Manager Constants

This section describes the constants used with the UDA Manager, which include the following constant types:

- [Control Flags](#)
- [Error Constants](#)
- [Object Option Flags](#)
- [Miscellaneous Constants](#)

### Control Flags

Use the control flag constants to control UDA objects with the [UDAControl](#) macro.

---

| Constant         | Value | Description                                                                    |
|------------------|-------|--------------------------------------------------------------------------------|
| kUDAReinitialize | 1     | Used with the <a href="#">UDAControl</a> macro to reinitialize the UDA object. |

---

### Error Constants

At the time of this writing, there is only one error constant associated with the UDA object API.

---

| Constant      | Description                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------|
| udaErrControl | Returned by the <a href="#">UDAControl</a> macro when the control parameter is not valid for the UDA object. |

---

### Object Option Flags

You use the object option flag constants to determine information about the internal state of UDA objects. Note that the [UDAEndOfReader](#) and [UDAMoreData](#) macros provide you with a convenient means of accessing this same information.

## Unified Data Access Manager

### UDA Manager Functions

---

| Constant        | Value | Description                                                                       |
|-----------------|-------|-----------------------------------------------------------------------------------|
| kUDAEndOfReader | 1     | Indicates that the UDA reader has reached the end of its data.                    |
| kUDAMoreData    | 2     | Indicates that the UDA reader needs more space in the read buffer to do its work. |

---

### Miscellaneous Constants

| Constant                 | Value  | Description                                                                                                                     |
|--------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------|
| kUDAZeroTerminatedBuffer | 0xFFFF | Indicates that the buffer is a null-terminated string. Use this value when creating or reinitializing a UDAMemoryReader object. |

---

## UDA Manager Functions

### UDAControl

|                    |                                                                                                                                                                                                                                                                                                                                                                    |              |                                                                                                                                                                                                            |              |                                                         |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|---------------------------------------------------------|
| <b>Purpose</b>     | Applies controls to a UDA object.                                                                                                                                                                                                                                                                                                                                  |              |                                                                                                                                                                                                            |              |                                                         |
| <b>Declared In</b> | UDAMgr.h                                                                                                                                                                                                                                                                                                                                                           |              |                                                                                                                                                                                                            |              |                                                         |
| <b>Prototype</b>   | Err UDAControl (UDAObjectType* ioObjectP, UInt16 parameter, va_args)                                                                                                                                                                                                                                                                                               |              |                                                                                                                                                                                                            |              |                                                         |
| <b>Parameters</b>  | <table><tr><td>-&gt; ioObjectP</td><td>A pointer to the <a href="#">UDAObjectType</a> object that you want to control. This can be a <a href="#">UDAREaderType</a>, a <a href="#">UDAFilterType</a>, or a <a href="#">UDAWriterType</a> object.</td></tr><tr><td>-&gt; parameter</td><td>The control action that you want applied to the object.</td></tr></table> | -> ioObjectP | A pointer to the <a href="#">UDAObjectType</a> object that you want to control. This can be a <a href="#">UDAREaderType</a> , a <a href="#">UDAFilterType</a> , or a <a href="#">UDAWriterType</a> object. | -> parameter | The control action that you want applied to the object. |
| -> ioObjectP       | A pointer to the <a href="#">UDAObjectType</a> object that you want to control. This can be a <a href="#">UDAREaderType</a> , a <a href="#">UDAFilterType</a> , or a <a href="#">UDAWriterType</a> object.                                                                                                                                                         |              |                                                                                                                                                                                                            |              |                                                         |
| -> parameter       | The control action that you want applied to the object.                                                                                                                                                                                                                                                                                                            |              |                                                                                                                                                                                                            |              |                                                         |

-> va\_args      Additional parameters, as required for the control and object type.

**Result**      Returns `errNone` if no error, or `udaErrorClass` if the control parameter is not valid for the `ioObjectP`.

**Comments**      The `UDAControl` function applies a control action to a UDA object. You may need to supply additional parameters, depending on the object type and control parameter values.

The only control action defined in Palm OS 4.0 is `kUDAREinitialize`. You can use it as shown in [Table 86.1](#).

**Table 86.1 UDAControl actions**

| Object Type                        | Usage                                                                    | Action                                                                                                                           |
|------------------------------------|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|

| <code>UDAExchangeWriterType</code> | <code>UDAControl(myExgWtr, kUDAREinitialize)</code>                      | Does nothing                                                                                                                     |
| <code>UDAMemoryReaderType</code>   | <code>UDAControl(myMemRdr, kUDAREinitialize, bufferP, bufferSize)</code> | Reinstalls a new buffer for the memory reader. See <a href="#">UDAMemoryReaderNew</a> for more information about the parameters. |

**Compatibility**      Implemented only if [4.0 New Feature Set](#) is present.

## UDADelete

- Purpose** Macro that deletes a UDA object.
- Declared In** UDAMgr.h
- Prototype** UDADelete (ioObjectP)
- Parameters** -> ioObjectP A pointer to the [UDAObjectType](#) object that you want to delete. This can be a [UDAREaderType](#), a [UDAFilterType](#), or a [UDAWriterType](#) object.
- Result** Returns nothing.
- Comments** The ioObjectP pointer is not valid after this macro completes.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## UDAEndOfReader

- Purpose** Macro that tests if the end of the reader has been reached.
- Declared In** UDAMgr.h
- Prototype** UDAEndOfReader (ioReaderP)
- Parameters** -> ioReaderP A pointer to a [UDAREaderType](#) object.
- Result** Returns true if the end of the reader referenced by ioReaderP has been reached, and false if not.
- Comments** The end of the reader has been reached.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## UDAFilterJoin

|                      |                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that joins a filter with a reader.                                                                                                                                                                                                                                                                                                                                                  |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>     | UDAFilterJoin (ioFilterP, newReaderP)                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>    | --> ioFilterP A pointer to a <a href="#">UDAFilterType</a> object.<br>--> newReaderP A pointer to the <a href="#">UDAREaderType</a> object with which you want the filter joined.                                                                                                                                                                                                         |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Comments</b>      | Each <a href="#">UDAFilterType</a> object receives its data from the <a href="#">UDAREaderType</a> object to which it is joined; this relationship is established when you create the filter object. You can use this macro to change the reader with which the filter is joined. Upon completion, the filter referenced by ioFilterP is joined with the reader referenced by newReaderP. |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                       |

## UDAInitiateWrite

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Macro that causes the <a href="#">UDAWriterType</a> object to read data and then write that data to output. |
| <b>Declared In</b> | UDAMgr.h                                                                                                    |
| <b>Prototype</b>   | UDAInitiateWrite (ioWriterP)                                                                                |
| <b>Parameters</b>  | -> ioWriterP A pointer to a <a href="#">UDAWriterType</a> object.                                           |
| <b>Result</b>      | Returns errNone if successful, and an error code if not.                                                    |

## Unified Data Access Manager

### UDA Manager Functions

---

**Comments** When you use this macro, the `ioWriterP` reads data from the reader to which it is joined. It reads data until the reader is empty, and then writes the data to the output medium.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### UDAMoreData

**Purpose** Macro that tests if there is more data available to read, but not enough room in the buffer to read it in.

**Declared In** `UDAMgr.h`

**Prototype** `UDAMoreData (ioReaderP)`

**Parameters** `-> ioReaderP` A pointer to a [UDAREaderType](#) object.

**Result** Returns `true` if there is more data available for the reader and `false` if there is no more data available.

**Comments** You can use this macro with [UDAREaderType](#) objects to determine if there is more data waiting to read. This can happen when the reader's buffer is full.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### UDARead

**Purpose** Macro that uses the specified [UDAREaderType](#) object to read data from the input source and place that data into the specified buffer.

**Declared In** `UDAMgr.h`

**Prototype** `UDARead (ioReaderP, bufferToFillP, bufferSize, errorP)`

**Parameters** `-> ioReaderP` A pointer to a [UDAREaderType](#) object that performs the read.

- > `bufferToFillP` A pointer to the buffer into which data is placed.
- > `bufferSize` The size of the buffer, in bytes.
- > `errorP` A pointer to an `Err` value that represents the result of the read operation; if the operation is successful, the value is set to `errNone`.

**Result** Returns the number of bytes that were actually read. This value can be less than or equal to the value of `bufferSize`.

**Comments** The reader reads from the input source associated with the reader object and places the data into the specified buffer, reading no more than `bufferSize` bytes of data.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## UDAWriterFlush

**Purpose** Macro that flushes the buffer used by the [UDAWriterType](#) object.

**Declared In** `UDAMgr.h`

**Prototype** `UDAWriterFlush (ioWriterP)`

**Parameters** -> `ioWriterP` A pointer to a `_UDAWriterType` object.

**Result** Returns `errNone` if successful, and an error code if not.

**Comments** You can use this macro to flush any data remaining in the buffer of the writer object referenced by `ioWriterP`. This causes any data in the buffer to be sent to the output medium.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## UDAWriterJoin

- Purpose** Macro that joins a writer object to a different reader object.
- Declared In** UDAMgr.h
- Prototype** `UDAWriterJoin (ioWriterP, newReaderP)`
- Parameters**
- > `ioWriterP` A pointer to a [UDAWriterType](#) object.
  - > `newReaderP` A pointer to the [UDAREaderType](#) object with which you want the writer joined.
- Result** Returns nothing.
- Comments** Each [UDAWriterType](#) object receives its data from the [UDAREaderType](#) object to which it is joined; this relationship is established when you create the writer object. You can use this macro to change the reader with which the writer is joined. Upon completion, the writer referenced by `ioWriterP` is joined with the reader referenced by `newReaderP`.
- Compatibility** Implemented only if 4.0 Feature Set is present.

## UDA Object Creation Functions

### UDAExchangeReaderNew

|                      |                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Creates a new <a href="#">UDAReaderType</a> object that you can use to read data from an Exchange Manager socket.        |
| <b>Declared In</b>   | UDAMgr.h                                                                                                                 |
| <b>Prototype</b>     | <code>UDAReaderType* UDAExchangeReaderNew<br/>(ExgSocketPtr socket)</code>                                               |
| <b>Parameters</b>    | -> socket      A pointer to an <a href="#">ExgSocketType</a> structure that describes the connection.                    |
| <b>Result</b>        | Returns a pointer to the newly created <a href="#">UDAReaderType</a> object, or NULL if the reader could not be created. |
| <b>Comments</b>      | Use this function to create a UDA Reader object that takes input from an Exchange Manager socket.                        |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present.                                                      |
| <b>See Also</b>      | <a href="#">ExgSocketType</a>                                                                                            |

### UDAExchangeWriterNew

|                    |                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Creates a new <a href="#">UDAWriterType</a> object that you can use to write data to an Exchange Manager socket. |
| <b>Declared In</b> | UDAMgr.h                                                                                                         |
| <b>Prototype</b>   | <code>UDAWriterType* UDAExchangeWriterNew<br/>(ExgSocketPtr socket, UDABufferSize bufferSize)</code>             |
| <b>Parameters</b>  | -> socket      A pointer to an <a href="#">ExgSocketType</a> structure that describes the connection.            |

## Unified Data Access Manager

### UDA Object Creation Functions

---

-> bufferSize The size, in bytes, of the buffer for the new writer object.

**Result** Returns a pointer to the newly created UDA Writer, or NULL if the writer could not be created.

**Comments** Use this function to create a UDA Writer object that sends output to an Exchange Manager socket.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [ExgSocketType](#)

## UDAMemoryReaderNew

**Purpose** Creates a new [UDAREaderType](#) object that you can use to read data from a memory buffer.

**Declared In** UDAMgr.h

**Prototype** UDAREaderType\* UDAMemoryReaderNew  
(const UInt8\* bufferP,  
UDABufferSize bufferSizeInBytes)

**Parameters**

-> bufferP A pointer to a buffer in memory from which data is read.

-> bufferSize The size of the buffer, in bytes. If this value is equal to kUDAZeroTerminatedBuffer, bufferP must point to a null-terminated string buffer.

**Result** Returns a pointer to the newly created [UDAREaderType](#) object, or NULL if the reader could not be created.

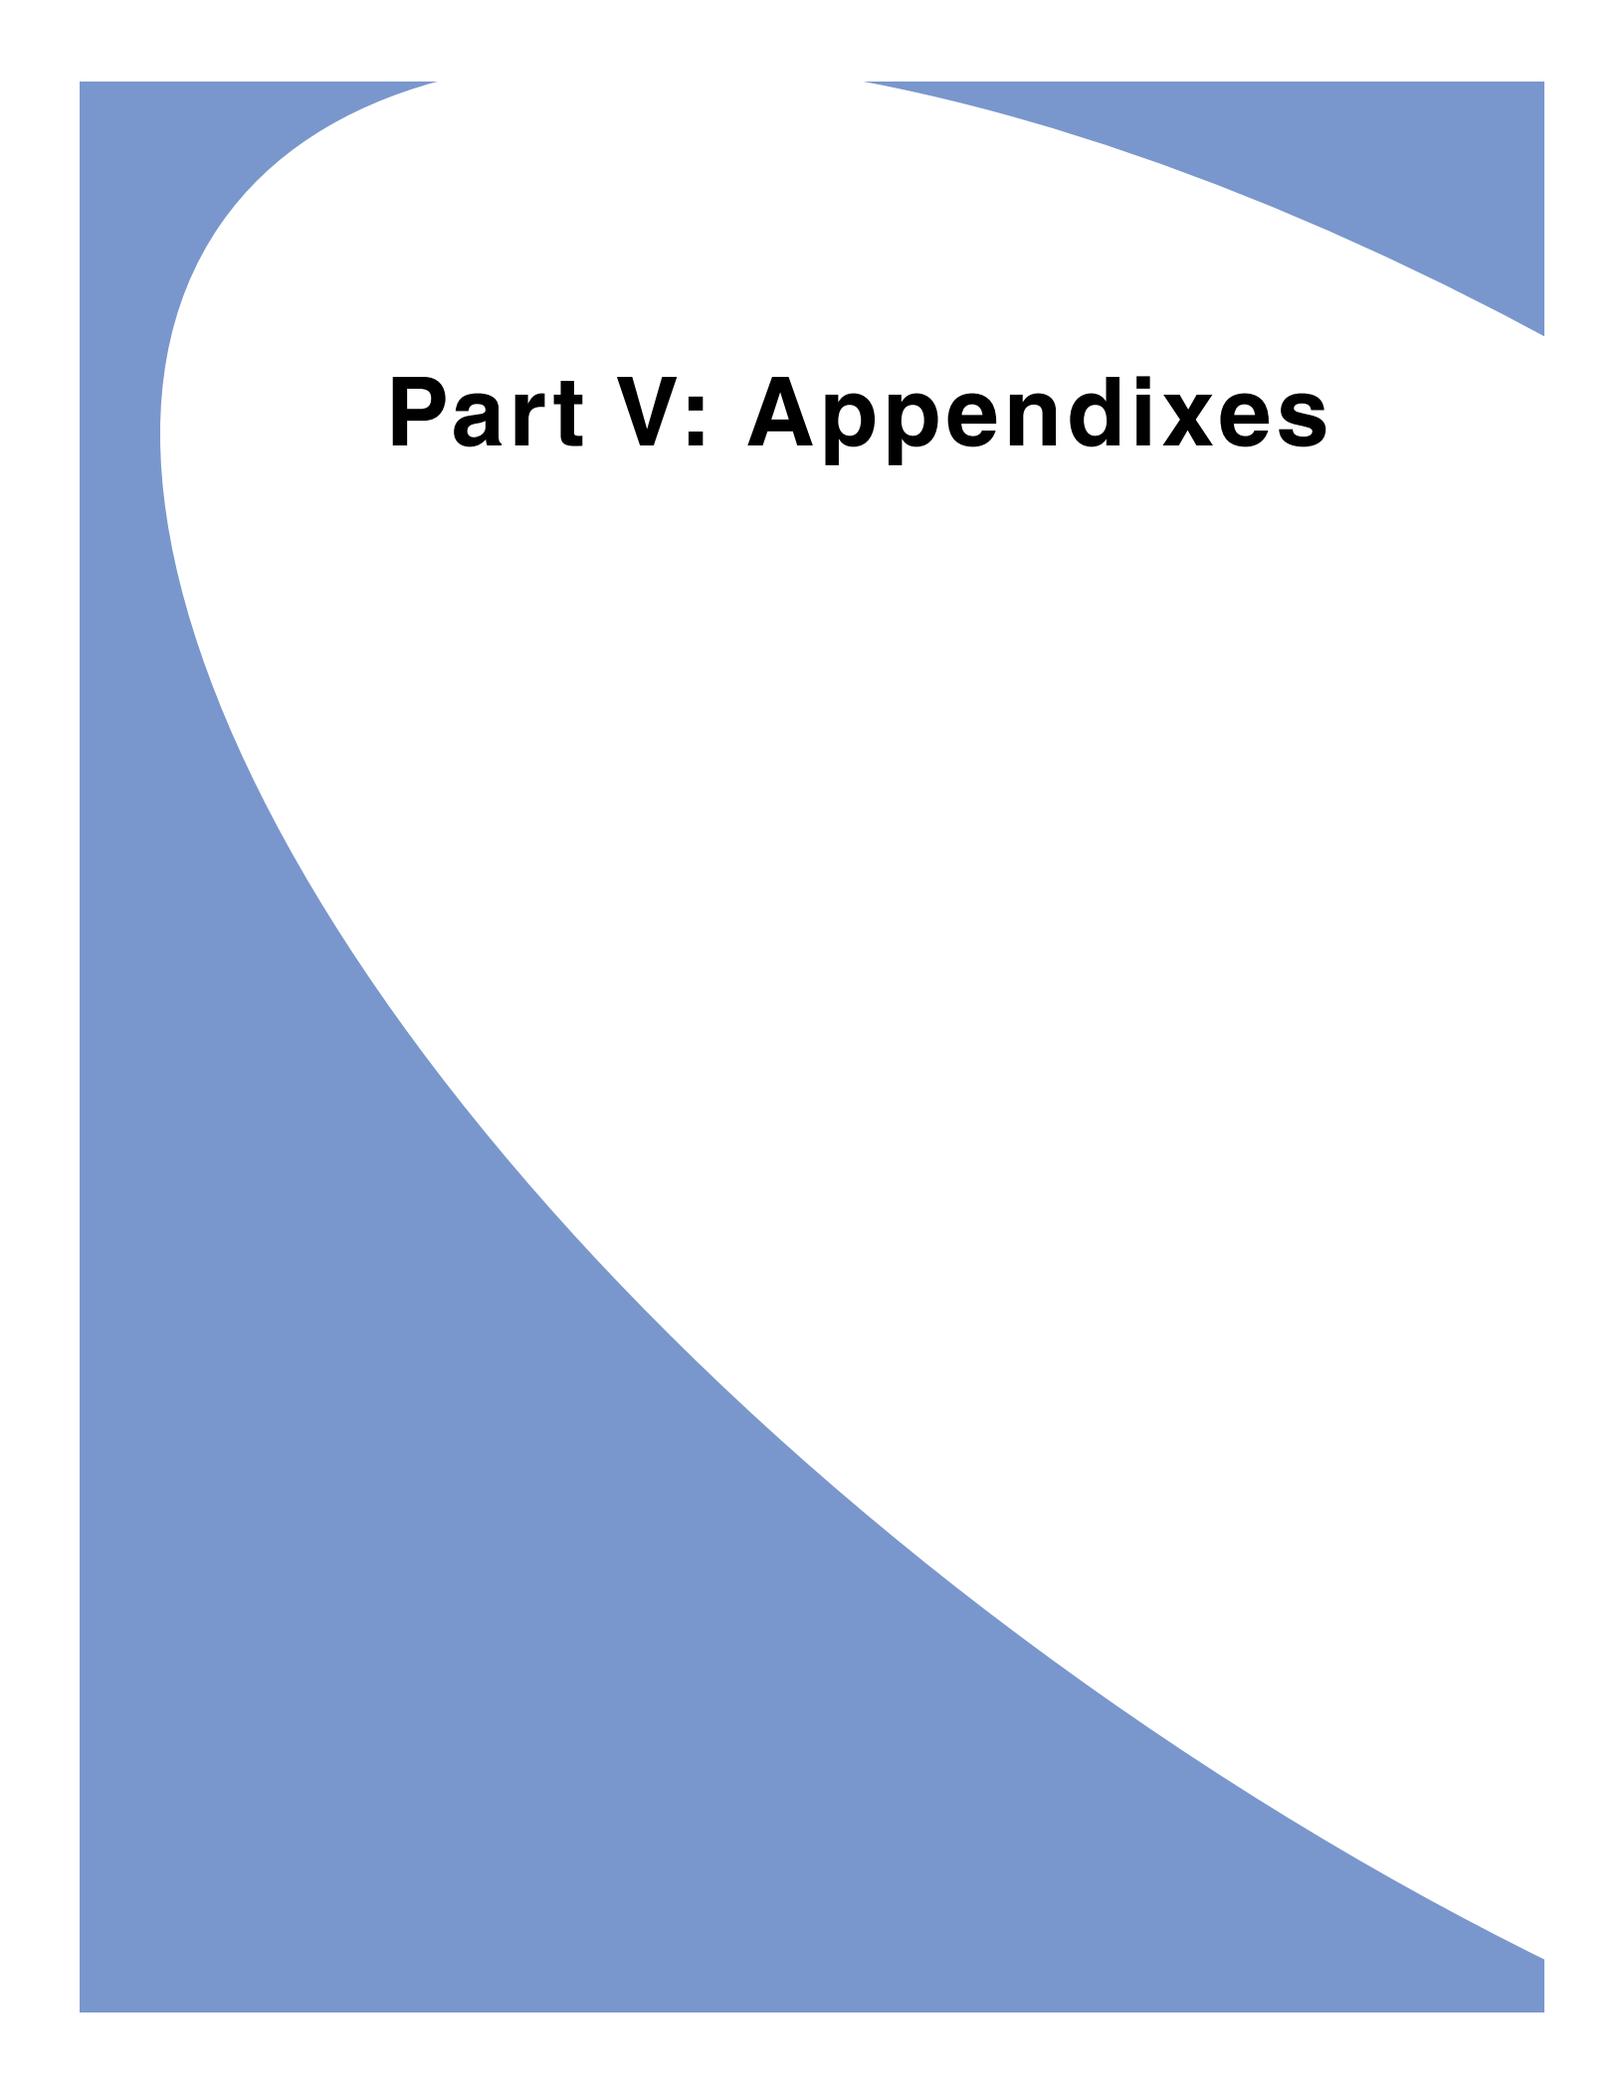

**Comments** Use this function to create a reader that takes input from memory.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

# B

## Compatibility Guide

---

This appendix lists groups of functions and other features (such as events and launch codes) that have been added to the Palm OS® after version 1.0.

Before you use any new functions or features in an application, you must check to ensure that they are implemented in the OS version your application is running on. Checking the OS version number is **not** a reliable indicator that a specific feature is present, since some later OS versions do not include features present in earlier versions. In order to ensure that your code is supported, you must check for the presence of individual features.

To make this check easier, this appendix lists new functions and features in groups such that all functions and features in a group are always implemented together in the ROM of a Palm™ device. This means that you can check for a single feature in that group and be assured that if that feature is present then all functions and features in that group are implemented.

Each group includes a recommended test to check if it is implemented. The following groups are described:

- [2.0 New Feature Set](#)
- [3.0 New Feature Set](#)
- [3.1 New Feature Set](#)
- [3.2 New Feature Set](#)
- [International Feature Set](#)
- [Japanese Feature Set](#)
- [Wireless Internet Feature Set](#)
- [New Serial Manager Feature Set](#)
- [Connection Manager Feature Set](#)
- [3.5 New Feature Set](#)
- [Notification Feature Set](#)

## Compatibility Guide

### 2.0 New Feature Set

---

- [4.0 New Feature Set](#)
- [Expansion Manager Feature Set](#)
- [VFS Manager Feature Set](#)
- [Bluetooth Library Feature Set](#)
- [High-Density Display Feature Set](#)
- [Sound Stream Feature Set](#)
- [5.0 New Feature Set](#)
- [5.1 New Feature Set](#)

## 2.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 2.0 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romversion);
```

The `romversion` parameter should be 0x02003000 or greater.

### Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdLookup](#)  
[sysAppLaunchCmdPanelCalledFromApp](#)  
[sysAppLaunchCmdReturnFromPanel](#)  
[sysAppLaunchCmdSystemLock](#)

### Functions

This feature set adds the following functions:

|                                          |                                   |
|------------------------------------------|-----------------------------------|
| <a href="#">CategoryInitialize</a>       | <a href="#">CategorySetName</a>   |
| <a href="#">DmDeleteCategory</a>         | <a href="#">DmDatabaseProtect</a> |
| <a href="#">EvtAddUniqueEventToQueue</a> | <a href="#">EvtEventAvail</a>     |
| <a href="#">EvtSysEventAvail</a>         |                                   |

|                                                   |                                               |
|---------------------------------------------------|-----------------------------------------------|
| <a href="#"><u>FldGetNumberOfBlankLines</u></a>   | <a href="#"><u>FldGetScrollValues</u></a>     |
| <a href="#"><u>FldSetInsertionPoint</u></a>       |                                               |
| <a href="#"><u>FntGetScrollValues</u></a>         | <a href="#"><u>FntWordWrap</u></a>            |
| <a href="#"><u>FntWordWrapReverseNLines</u></a>   |                                               |
| <a href="#"><u>FrmPointInTitle</u></a>            | <a href="#"><u>FrmSetMenu</u></a>             |
| <a href="#"><u>FrmSetObjectBounds</u></a>         |                                               |
| <a href="#"><u>KeySetMask</u></a>                 | <a href="#"><u>LocGetNumberSeparator</u></a>  |
|                                                   | <a href="#"><u>s</u></a>                      |
| <a href="#"><u>LstScrollList</u></a>              | <a href="#"><u>LstGetVisibleItems</u></a>     |
| <a href="#"><u>MemCmp</u></a>                     | <a href="#"><u>MenuSetActiveMenuRscID</u></a> |
|                                                   | <a href="#"><u>D</u></a>                      |
| <a href="#"><u>PhoneNumberLookup</u></a>          |                                               |
| <a href="#"><u>PrefSetPreference</u></a>          | <a href="#"><u>PrefGetPreference</u></a>      |
| <a href="#"><u>SclDrawScrollBar</u></a>           | <a href="#"><u>SclGetScrollBar</u></a>        |
| <a href="#"><u>SclHandleEvent</u></a>             | <a href="#"><u>SclSetScrollBar</u></a>        |
| <a href="#"><u>SerControl</u></a>                 |                                               |
| <a href="#"><u>StrDelocalizeNumber</u></a>        | <a href="#"><u>StrLocalizeNumber</u></a>      |
| <a href="#"><u>StrNCaselessCompare</u></a>        | <a href="#"><u>StrNCat</u></a>                |
| <a href="#"><u>StrNCompare</u></a>                | <a href="#"><u>StrNCopy</u></a>               |
| <a href="#"><u>StrPrintf</u></a>                  | <a href="#"><u>StrVPrintf</u></a>             |
| <a href="#"><u>SysBinarySearch</u></a>            | <a href="#"><u>SysCreateDataBaseList</u></a>  |
| <a href="#"><u>SysCreatePanelList</u></a>         | <a href="#"><u>SysErrString</u></a>           |
| <a href="#"><u>SysGraffitiReferenceDialog</u></a> | <a href="#"><u>SysLibLoad</u></a>             |
| <a href="#"><u>SysStringByIndex</u></a>           | <a href="#"><u>SysTicksPerSecond</u></a>      |
| <a href="#"><u>TblHasScrollBar</u></a>            | <a href="#"><u>TblSetBounds</u></a>           |
| <a href="#"><u>TblSetColumnEditIndicator</u></a>  | <a href="#"><u>TblSetRowStaticHeight</u></a>  |
| <a href="#"><u>WinSetWindowBounds</u></a>         |                                               |

## Existing Functions that Changed

Several functions that existed in 1.0 were changed in 2.0:

## Compatibility Guide

### 2.0 New Feature Set

---

[CategoryCreateList](#) (old function renamed [CategoryCreateListV10](#))

[CategoryEdit](#) (old function renamed [CategoryEditV10](#))

[CategoryFreeList](#) (old function renamed [CategoryFreeListV10](#))

[CategorySelect](#) (old function renamed [CategorySelectV10](#))

[SelectDay](#) (old function renamed [SelectDayV10](#))

[DmFindSortPosition](#) (old function renamed [DmFindSortPositionV10](#))

[PrefGetAppPreferences](#) (old function renamed [PrefGetAppPreferencesV10](#))

[PrefOpenPreferenceDB](#) (old function renamed [PrefOpenPreferenceDBV10](#))

[PrefSetAppPreferences](#) (old function renamed [PrefSetAppPreferencesV10](#))

[SerReceive](#) (old function renamed [SerReceive10](#))

[SerSend](#) (old function renamed [SerSend10](#))

[SysKeyboardDialog](#) (old function renamed [SysKeyboardDialogV10](#))

## Other Changes

As a rule, all Palm OS applications developed with the 1.0 SDK should run error-free on the latest device. There are two possible pitfalls for 1.0 applications:

- **fldChangedEvent Change**—The operating system now correctly sends a `fldChangedEvent` whenever a field object is changed. Previously, the event was at times not sent, especially when a `FldSetText` operation was performed. If your application doesn't catch the events that are now sent, it may have problems.
- **Non-standard tools**—If your application was not developed with Metrowerks Code Warrior for the Palm OS, it may run

into problems. One known problem can occur if the application:

- was compiled with optimization turned on
- uses system preferences

## 3.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.0 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The `romVersion` parameter should be greater than or equal to `0x03003000`, which can be constructed using the `sysMakeROMVersion` macro:

```
sysMakeROMVersion(3, 0, 0, sysROMStageRelease, 0)
```

### Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdExgAskUser](#)  
[sysAppLaunchCmdExgReceiveData](#)

In addition, the launch code [sysAppLaunchCmdGoto](#) is now also sent by the exchange manager, in addition to its use by the global find operation.

### Font

This feature set adds the following font:

`largeBoldFont`

### Functions

This feature set adds the following functions:

#### Dynamic User Interface Functions

|                                    |                                   |
|------------------------------------|-----------------------------------|
| <a href="#">CtlNewControl</a>      | <a href="#">FrmNewLabel</a>       |
| <a href="#">CtlValidatePointer</a> | <a href="#">FrmRemoveObject</a>   |

| <a href="#">IrIAS_GetOctetStringLength</a> | <a href="#">IrSetConTypeTTP</a>           |
| <a href="#">IrIAS_GetType</a>              | <a href="#">IrSetDeviceInfo</a>           |
| <a href="#">IrIAS_GetUserString</a>        | <a href="#">IrTestReq</a>                 |
| <a href="#">IrIAS_GetUserStringCharSet</a> | <a href="#">IrUnbind</a>                  |

For more information, see the chapter [Beaming \(Infrared Communication\)](#) in the *Palm OS Programmer's Companion*, vol. II, *Communications*.

## Miscellaneous Functions

|                                                 |                                 |
|-------------------------------------------------|---------------------------------|
| <a href="#">FrmRestoreActiveState</a>           | <a href="#">SysGetROMToken</a>  |
| <a href="#">FrmSaveActiveState</a>              | <a href="#">SysGetStackInfo</a> |
| <a href="#">ScrDisplayMode</a>                  | <a href="#">SysGremlins</a>     |
| <a href="#">SysGetAppInfo</a> (system use only) | <a href="#">TblGetItemFont</a>  |
| <a href="#">SysGetOSVersionString</a>           | <a href="#">TblSetItemFont</a>  |

## Existing Functions that Changed

Two functions that existed in 2.0 were changed in 3.0:

[CategoryEdit](#) (old function renamed [CategoryEditV20](#))

[SysBatteryInfo](#) (old function renamed [SysBatteryInfoV20](#))

## Other Changes

- The dynamic heap has been increased in size to 96 KB.
- Storage RAM is no longer subdivided into multiple storage heaps of 64 KB each. All storage RAM on a memory card is configured as a single storage heap.
- Each flash ROM-based Palm device holds a serial number that identifies it uniquely and can be retrieved via [SysGetROMToken](#). For more information, see “[Retrieving the ROM Serial Number](#)” on page 353 of the *Palm OS Programmer’s Companion*, vol. I.
- The Application Launcher (accessed via the silkscreen “Applications” button) is now an application, rather than a popup. The `SysAppLauncherDialog` function, which provides the API to the old popup launcher, is still present in Palm OS 3.0 for compatibility purposes, but has not been updated and generally should not be used. For more information, see “[Application Launcher](#)” on page 153 of the *Palm OS Programmer’s Companion*, vol. I.
- The sound manager supports MIDI sound files, adding new sounds, asynchronous playback, and other features. There are also new selectors for setting the volume preferences. For more information, see the section “[System Boot and Reset](#)” on page 337 of the *Palm OS Programmer’s Companion*, vol. I.

## Compatibility Guide

### 3.1 New Feature Set

---

The following functions existed in the system previously, but were not documented:

[RctCopyRectangle](#)                      [RctOffsetRectangle](#)  
[RctGetIntersection](#)                  [RctPtInRectangle](#)  
[RctInsetRectangle](#)                   [RctSetRectangle](#)

The following event type existed in the system previously, but was not previously documented:

[frmGotoEvent](#)

## 3.1 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.1 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The romVersion parameter should be greater than or equal to 0x03103000, which can be constructed using the sysMakeROMVersion macro:

```
sysMakeROMVersion(3, 1, 0, sysROMStageRelease, 0)
```

### Functions

This feature set adds the following functions:

[ChrHorizEllipsis](#)  
[ChrNumericSpace](#)  
ContrastAdjust  
[FntWidthToOffset](#)  
[FtrPtrNew](#)  
[FtrPtrFree](#)  
[FtrPtrResize](#)  
[SelectOneTime](#)  
[WinDrawChar](#)  
[WinDrawTruncChars](#)

---

**NOTE:** The `PalmOSGlue.lib` provides compatibility functions and macros for `ChrHorizEllipsis`, `ChrNumericSpace`, `WinDrawChar`, and `WinDrawTruncChars`. If you want to use these functions on systems that don't have the 3.1 feature set, you can link your application with `PalmOSGlue.lib`. See the chapter "[PalmOSGlue Library](#)" on page 1891 for more information.

---

## Changes to the Character Encoding

Starting in Palm OS 3.1, the character encoding used on most systems is Microsoft Windows code page 1252. Versions prior to 3.1 used an encoding that was very similar to code page 1252 but did not follow it exactly. The following changes to the character set are introduced in Palm OS 3.1:

- Some of the special Palm OS glyphs in the high ASCII range (such as the shortcut stroke and the command stroke) have been moved down into the control code range, and other characters (such as the numeric space and horizontal ellipsis) have been copied into the control range so that they're guaranteed to exist in every encoding. For the numeric space and horizontal ellipsis, you can use the macros [ChrNumericSpace](#) and [ChrHorizEllipsis](#) to return the appropriate character regardless of the character map. In `PalmOSGlue.lib`, these two macros are named `TxtGlueGetNumericSpaceChar` and `TxtGlueGetHorizEllipsisChar`, respectively.
- The four playing-card characters have been moved from the high ASCII range in the standard four fonts to the 9-point Symbol font.

## Other Changes in 3.1

- Palm OS 3.1 supports a new processor: the EZ Dragonball processor. This processor is compatible with the existing Dragonball processor, so your application should run

## Compatibility Guide

### 3.1 New Feature Set

---

without changes as long as it doesn't access registers or system globals directly.

If your application needs to know if it is running on an EZ Dragonball, it can check using the following code:

```
DWord id, chip;
Word revision;
Err err;
err = FtrGet(sysFtrCreator,
             sysFtrNumProcessorID, &id);
if (!err) {
    chip = id & sysFtrNumProcessorMask;
    revision = id & 0x0ffff;
    if (chip==sysFtrNumProcessor328)
        // traditional Dragonball
    else if (chip==sysFtrNumProcessorEZ)
        // Dragonball EZ
}
```

- The constant `preferenceDataVersion` was removed and replaced with `preferenceDataVerLatest`.
- Character variables are now two bytes long. The type `WChar` defines a character variable.
- The `keyDownEvent` structure's `chr` field (which contains the input character) has been changed from a `Word` to a `WChar`.
- The string manager functions [StrChr](#) and [StrStr](#) now treat buffers as characters, not arbitrary byte arrays. If you previously used these functions to search data buffers, your code may no longer work.
- The string manager function [StrToLower](#) can now handle any type of characters, including accented characters.
- The underline attribute of [FieldAttrType](#) now has support for the value 2. Previously, the only underline modes available were no underline (0) and gray underline (1). In Palm OS 3.1 and higher, the value 2 is interpreted as solid underline. The `UnderlineModeType` enum defined in `Window.h` defines the possible values for the underline attribute.

- The use of the [DmGetNextDatabaseByTypeCreator](#) `onlyLatestVers` parameter changed in 3.1. If `onlyLatestVers` is true, you only receive one matching database for each type/creator pair. In version 3.0 and earlier, you could receive multiple matching databases if `onlyLatestVers` was true. See that function's description for a more detailed description.

## 3.2 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.2 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The `romVersion` parameter should be greater than or equal to `0x03203000`, which can be constructed using the `sysMakeROMVersion` macro:

```
sysMakeROMVersion(3, 2, 0, sysROMStageRelease, 0)
```

### Functions

This feature set adds the following functions:

|                                        |                                           |
|----------------------------------------|-------------------------------------------|
| <a href="#">AlmGetProcAlarm</a>        | <a href="#">NetLibConfigIndexFromName</a> |
| <a href="#">AlmSetProcAlarm</a>        | <a href="#">NetLibConfigList</a>          |
| <a href="#">ClipboardAppendItem</a>    | <a href="#">NetLibConfigMakeActive</a>    |
| <a href="#">DmGetDatabaseLockState</a> | <a href="#">NetLibConfigRename</a>        |
| <a href="#">ErrAlert</a>               | <a href="#">NetLibConfigSaveAs</a>        |
| <a href="#">NetLibConfigAliasGet</a>   | <a href="#">NetLibOpenConfig</a>          |
| <a href="#">NetLibConfigAliasSet</a>   | <a href="#">SndPlaySmfResource</a>        |
| <a href="#">NetLibConfigDelete</a>     |                                           |

Note that the `NetLib...` functions, although present in the 3.2 New Feature Set, are first declared in the Palm OS 5 SDK.

## Existing Functions that Changed

Two functions that existed in 3.0 were changed in 3.2:

[SysGremlins](#) was removed and replaced with a `SysGremlins` macro that maps it to the function `HostGremlinIsRunning`. The prototype is slightly different, but you can still call `SysGremlins` in the same way you did before.

[PrgStartDialog](#) (old function renamed [PrgStartDialogV31](#))

## Other Changes in 3.2

- The prototype for the system use only function `AlmDisplayAlarm` changed from no return value to a Boolean return value. This change may affect system patches and extensions that intercept `AlmDisplayAlarm` calls.

## International Feature Set

You can check that this feature set is implemented by checking for the existence of the international manager. You can check by calling [FtrGet](#) as follows:

```
err = FtrGet(sysFtrCreator, sysFtrNumIntlMgr,
            &value);
```

If the international manager is installed, the `value` parameter will be non-zero and the returned error should also be zero (for no error).

You can learn more about the international manager by reading the chapter “[Localized Applications](#)” on page 363 in the *Palm OS Programmer’s Companion*, vol. I.

---

**NOTE:** If you want to use international functions on systems that don’t have the international feature, you can link your application with `PalmOSGlue.lib`. The functions in this library are the same as those listed below except that they use the prefix “`TxtGlue`” instead of “`Txt`.” For more information, see the chapter “[PalmOSGlue Library](#)” on page 1891.

---

## Functions

This feature set adds the following functions:

### Text Manager Functions

|                                           |                                               |
|-------------------------------------------|-----------------------------------------------|
| <a href="#"><u>TxtByteAttr</u></a>        | <a href="#"><u>TxtCharXAttr</u></a>           |
| <a href="#"><u>TxtCaselessCompare</u></a> | <a href="#"><u>TxtCompare</u></a>             |
| <a href="#"><u>TxtCharAttr</u></a>        | <a href="#"><u>TxtEncodingName</u></a>        |
| <a href="#"><u>TxtCharBounds</u></a>      | <a href="#"><u>TxtFindString</u></a>          |
| <a href="#"><u>TxtCharEncoding</u></a>    | <a href="#"><u>TxtGetChar</u></a>             |
| <a href="#"><u>TxtCharIsAlNum</u></a>     | <a href="#"><u>TxtGetNextChar</u></a>         |
| <a href="#"><u>TxtCharIsAlpha</u></a>     | <a href="#"><u>TxtGetPreviousChar</u></a>     |
| <a href="#"><u>TxtCharIsCntrl</u></a>     | <a href="#"><u>TxtCharIsValid</u></a>         |
| <a href="#"><u>TxtCharIsDigit</u></a>     | <a href="#"><u>TxtMaxEncoding</u></a>         |
| <a href="#"><u>TxtCharIsGraph</u></a>     | <a href="#"><u>TxtNextCharSize</u></a>        |
| <a href="#"><u>TxtCharIsHardKey</u></a>   | <a href="#"><u>TxtPreviousCharSize</u></a>    |
| <a href="#"><u>TxtCharIsHex</u></a>       | <a href="#"><u>TxtReplaceStr</u></a>          |
| <a href="#"><u>TxtCharIsLower</u></a>     | <a href="#"><u>TxtSetNextChar</u></a>         |
| <a href="#"><u>TxtCharIsPrint</u></a>     | <a href="#"><u>TxtStrEncoding</u></a>         |
| <a href="#"><u>TxtCharIsPunct</u></a>     | <a href="#"><u>TxtTransliterate</u></a>       |
| <a href="#"><u>TxtCharIsSpace</u></a>     | <a href="#"><u>TxtGetTruncationOffset</u></a> |
| <a href="#"><u>TxtCharIsUpper</u></a>     | <a href="#"><u>TxtWordBounds</u></a>          |
| <a href="#"><u>TxtCharSize</u></a>        |                                               |

### Other Functions

[IntlGetRoutineAddress](#)

### Removed Functions and Macros

If the international feature set exists, then the following functions and macros are no longer available:

## Compatibility Guide

### Japanese Feature Set

---

[GetCharAttr](#)  
[GetCharCaselessValue](#)  
[GetCharSortValue](#)  
IsAscii  
IsAlNum  
IsAlpha  
IsCntrl  
IsDigit  
IsGraph  
IsLower  
IsPrint  
IsPunct  
IsSpace  
IsUpper  
IsHex  
IsDelim

## Japanese Feature Set

You can check that the Japanese feature set is implemented by checking if the unit is Japanese. You can check by calling [FtrGet](#) as follows:

```
err = FtrGet(sysFtrCreator, sysFtrNumEncoding,  
&value);
```

The unit has the Japanese OS if the value parameter is `charEncodingCP932`.

For further information about the Japanese implementation, see the section "[Notes on the Japanese Implementation](#)" in the *Palm OS Programmer's Companion*, vol. I.

## Wireless Internet Feature Set

You can check that this feature set is implemented by checking for the existence of the Web Clipping Application Viewer (*Viewer*) and iMessenger™ applications. Here's an example of how to check for Viewer:

```
DmSearchStateType searchState;  
UInt16 cardNo;  
LocalID dbID;  
err = DmGetNextDatabaseByTypeCreator(true,  
&searchState, sysFileTApplication,  
sysFileCClipper, true, &cardNo, &dbID);
```

If Viewer is not present, the `DmGetNextDatabaseByTypeCreator` routine returns an error. To check for iMessenger, you can use the creator type `sysFileCMessaging`.

---

**NOTE:** The Viewer was formerly described as the Clipper.

---

You can learn more about the Palm.Net™ system for wireless Internet access and the programmatic interfaces to the Viewer and iMessenger applications by reading the chapter “[Internet and Messaging Applications](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*. For a more complete description, see the *Web Clipping Developer’s Guide*.

## Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdAddRecord](#) (for iMessenger application; existed for Mail in 3.0)  
[sysAppLaunchCmdGoToURL](#)  
[sysAppLaunchCmdOpenDB](#)  
[sysAppLaunchCmdURLParams](#)

## Events

This feature set adds the following events:

[inetSockReadyEvent](#)  
[inetSockStatusChangeEvent](#)

This feature set also adds the following `keyDownEvent` key codes:

## Compatibility Guide

### New Serial Manager Feature Set

---

vchrHardAntenna  
vchrRadioCoverageOK  
vchrRadioCoverageFail

These key codes are described in the section [Wireless keyDownEvent Key Codes](#).

## Functions

This feature set adds the following functions.

### Internet Library Functions

For more information, see the chapter “[Network Communication](#)” in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

|                                            |                                          |
|--------------------------------------------|------------------------------------------|
| <a href="#">INetLibCacheGetObject</a>      | <a href="#">INetLibSockClose</a>         |
| <a href="#">INetLibCacheList</a>           | <a href="#">INetLibSockConnect</a>       |

| <a href="#">INetLibOpen</a>                | <a href="#">INetLibURLOpen</a>           |
| <a href="#">INetLibSettingGet</a>          | <a href="#">INetLibURLsAdd</a>           |
| <a href="#">INetLibSettingSet</a>          | <a href="#">INetLibWiCmd</a>             |

## New Serial Manager Feature Set

The New Serial Manager feature set has two different versions.

## New Serial Manager Feature Set Version 1

You can check that this feature set is implemented by checking for the existence of the new Serial Manager. You can check by calling [FtrGet](#) as follows:

```
err = FtrGet(sysFileCSerialMgr,  
            sysFtrNewSerialPresent, &value);
```

If the new Serial Manager is installed, the `value` parameter will be non-zero and the returned error should also be zero (for no error).

You can learn more about the new Serial Manager and Connection Manager by reading the sections “[The Serial Manager](#)” on page 92 and “[The Connection Manager](#)” on page 116 in the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

This feature set adds the following functions.

### Serial Manager Functions

|                                       |                                       |
|---------------------------------------|---------------------------------------|
| <a href="#">SrmClearErr</a>           | <a href="#">SrmReceiveFlush</a>       |
| <a href="#">SrmClose</a>              | <a href="#">SrmReceiveWait</a>        |
| <a href="#">SrmControl</a>            | <a href="#">SrmReceiveWindowClose</a> |
| <a href="#">SrmGetDeviceCount</a>     | <a href="#">SrmReceiveWindowOpen</a>  |
| <a href="#">SrmGetDeviceInfo</a>      | <a href="#">SrmSend</a>               |
| <a href="#">SrmGetStatus</a>          | <a href="#">SrmSendCheck</a>          |
| <a href="#">SrmOpen</a>               | <a href="#">SrmSendFlush</a>          |
| <a href="#">SrmOpenBackground</a>     | <a href="#">SrmSendWait</a>           |
| <a href="#">SrmPrimeWakeupHandler</a> | <a href="#">SrmSetReceiveBuffer</a>   |
| <a href="#">SrmReceive</a>            | <a href="#">SrmSetWakeupHandler</a>   |
| <a href="#">SrmReceiveCheck</a>       | <a href="#">WakeupHandlerProcPtr</a>  |

### Virtual Driver Functions

|                                      |                                   |
|--------------------------------------|-----------------------------------|
| <a href="#">DrvEntryPointProcPtr</a> | <a href="#">VdrvStatusProcPtr</a> |
| <a href="#">GetSizeProcPtr</a>       | <a href="#">VdrvWriteProcPtr</a>  |
| <a href="#">GetSpaceProcPtr</a>      | <a href="#">WriteBlockProcPtr</a> |
| <a href="#">VdrvControlProcPtr</a>   | <a href="#">WriteByteProcPtr</a>  |
| <a href="#">VdrvOpenProcPtr</a>      |                                   |

## Compatibility Guide

### New Serial Manager Feature Set

---

#### Connection Manager Functions

[CncAddProfile](#)

[CncGetProfileInfo](#)

[CncDeleteProfile](#)

[CncGetProfileList](#)

#### Serial Link Manager Function

[SlkSocketPortID](#)

## New Serial Manager Feature Set Version 2

You can check that version 2 of the new Serial Manager feature set is implemented by checking the Serial Manager version number and the Palm OS version number. You can check by calling [FtrGet](#) as follows:

```
err = FtrGet(sysFileCSerialMgr,  
            sysFtrNewSerialVersion, &value);  
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The new Serial Manager is present if:

- Both calls to [FtrGet](#) return zero (for no error).
- The value parameter is 2.
- The romVersion parameter is 0x04003000, which can be constructed using the `sysMakeROMVersion` macro:  

```
sysMakeROMVersion(4, 0, 0, sysROMStageRelease, 0)
```

This feature set adds the following functions.

#### Serial Manager Functions

[SrmCustomControl](#)

[SrmExtOpen](#)

[SrmExtOpenBackground](#)

#### Virtual Driver Functions

[VdrvControlCustomProcPtr](#) [VdrvOpenProcV4Ptr](#)

[SignalCheckPtr](#)

---

**IMPORTANT:** Some Handspring devices ship with Palm OS version 3.5 but have new Serial Manager feature set version 2. These devices support the `SignalCheckPtr` virtual driver function and have expanded functionality for USB support, but they do not support the other function calls in this feature set.

---

You can learn more about the new Serial Manager by reading the chapter “[Serial Communication](#)” on page 89 of *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Connection Manager Feature Set

You can check that the Connection Manager feature set is implemented by checking the value of the Connection Manager feature. You can check by calling [FtrGet](#) as follows:

```
err = FtrGet(kCncFtrCncMgrCreator,  
            kCncFtrCncMgrVersion, &version);
```

The `version` parameter should be greater than or equal to `0x00040001`. In the 4.0 Palm OS SDK, this value is represented by the `kCncMgrVersion` constant.

---

**NOTE:** An earlier version of the Connection Manager is available if [New Serial Manager Feature Set Version 1](#) is present.

---

## Functions

This feature set adds the following functions:

|                                          |                                         |
|------------------------------------------|-----------------------------------------|
| <a href="#">CncProfileCloseDB</a>        | <a href="#">CncProfileGetIDFromName</a> |
| <a href="#">CncProfileCount</a>          | <a href="#">CncProfileGetIndex</a>      |
| <a href="#">CncProfileCreate</a>         | <a href="#">CncProfileOpenDB</a>        |
| <a href="#">CncProfileDelete</a>         | <a href="#">CncProfileSetCurrent</a>    |
| <a href="#">CncProfileGetCurrent</a>     | <a href="#">CncProfileSettingGet</a>    |
| <a href="#">CncProfileGetIDFromIndex</a> | <a href="#">CncProfileSettingSet</a>    |

## 3.5 New Feature Set

You can check that this feature set is implemented by checking that the system version is 3.5 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The `romVersion` parameter should be greater than or equal to `0x03503000`, which can be constructed using the `sysMakeROMVersion` macro:

```
sysMakeROMVersion(3, 5, 0, sysROMStageRelease, 0)
```

### Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdNotify](#)

### Events

This feature set adds the following events:

[frmGadgetEnterEvent](#)

[frmGadgetMiscEvent](#)

[menuCmdBarOpenEvent](#)

[menuOpenEvent](#)

### Functions

This feature set adds the following functions.

#### Bitmaps

[BmpBitsSize](#)

[BmpColortableSize](#)

[BmpCompress](#)

[BmpCreate](#)

[BmpDelete](#)

[BmpGetBits](#)

[BmpGetColortable](#)

[BmpSize](#)

[ColorTableEntries](#)

For more information on creating and using bitmaps, see the section “[Bitmaps](#)” on page 123 of the *Palm OS Programmer’s Companion*, vol. I.

## Controls

[CtlGetSliderValues](#)                      [CtlSetGraphics](#)  
[CtlNewGraphicControl](#)                [CtlSetSliderValues](#)  
[CtlNewSliderControl](#)

These functions add support for graphical buttons and slider controls. For more information, see the section “[Offscreen Windows](#)” on page 91 of the *Palm OS Programmer’s Companion*, vol. I.

## Forms

[FrmCustomResponseAlert](#)            [FrmSetGadgetHandler](#)  
[FrmNewGsi](#)

Among the changes to form functions is extended gadget support. For more information on gadgets and extended gadgets, see the section “[Custom UI Objects \(Gadgets\)](#)” on page 140 of the *Palm OS Programmer’s Companion*, vol. I.

## Menus

[MenuAddItem](#)                              [MenuCmdBarAddButton](#)  
[MenuCmdBarDisplay](#)                    [MenuCmdBarGetButtonData](#)  
[MenuHideItem](#)                            [MenuShowItem](#)

For more information on using menu functions, see the section “[Menus](#)” on page 105 of the *Palm OS Programmer’s Companion*, vol. I.

## Overlay Manager

[OmGetCurrentLocale](#)                    [OmLocaleToOverlayDBName](#)  
[OmGetIndexedLocale](#)                   [OmOverlayDBNameToLocale](#)  
[OmGetRoutineAddress](#)                 [OmSetSystemLocale](#)  
[OmGetSystemLocale](#)

For more information on using the overlay manager, see the section “[Using Overlays to Localize Resources](#)” on page 365 of the *Palm OS Programmer’s Companion*, vol. I.

## Private Records

[SecSelectViewStatus](#)                    [SecVerifyPW](#)

## Compatibility Guide

### 3.5 New Feature Set

---

#### Tables

[TblGetItemPtr](#)  
[TblRowMasked](#)

[TblSetColumnMasked](#)  
[TblSetRowMasked](#)

#### UI Colors

[UIColorGetTableEntryIndex](#)      [UIColorSetTableEntry](#)  
[UIColorGetTableEntryRGB](#)

For more information on using the UI Colors API, see the section “[Color and Grayscale Support](#)” on page 144 of the *Palm OS Programmer’s Companion*, vol. I.

#### UI Controls

[UIBrightnessAdjust](#)

[UIPickColor](#)

#### Windows

[WinCreateBitmapWindow](#)  
[WinDrawPixel](#)  
[WinErasePixel](#)  
[WinGetBitmap](#)  
[WinGetPatternType](#)  
[WinGetPixel](#)  
[WinIndexToRGB](#)  
[WinInvertPixel](#)  
[WinPaintBitmap](#)  
[WinPaintChar](#)  
[WinPaintChars](#)  
[WinPaintLine](#)  
[WinPaintLines](#)  
[WinPaintPixel](#)  
[WinPaintPixels](#)

[WinPaintRectangle](#)  
[WinPaintRectangleFrame](#)  
[WinPalette](#)  
[WinPopDrawState](#)  
[WinPushDrawState](#)  
[WinRGBToIndex](#)  
[WinScreenLock](#)  
[WinScreenMode](#)  
[WinScreenUnlock](#)  
[WinSetBackColor](#)  
[WinSetDrawMode](#)  
[WinSetForeColor](#)  
[WinSetPatternType](#)  
[WinSetTextColor](#)

For more information on using the window functions, see the section “[Drawing on the Palm Powered Handheld](#)” on page 72 of the *Palm OS Programmer’s Companion*, vol. I.

## Miscellaneous New Functions

[DmOpenDBNoOverlay](#)  
[ExgDoDialog](#)  
[DateToAscii](#)

[ResLoadConstant](#)  
[TxtParamString](#)

## Existing Functions that Changed

The following functions that existed prior to 3.5 have changed in release 3.5:

`ScrDisplayMode` was changed to [WinScreenMode](#).

`ContrastAdjust` was changed to [UIContrastAdjust](#).

[SelectTime](#) (old function renamed [SelectTimeV33](#))

## New Data Types

The data types `Byte`, `Word`, `DWord` and so on are now deprecated. It is recommend that you use the corresponding new data types. For example, use `Int16` instead of `SWord` and `UInt32` instead of `DWord`. In particular, the unfortunate distinction between `Handle`/`VoidHand` has been fixed; use `MemHandle` instead.

To learn in general how the type names changed, see the header file `PalmOSCompatibility.h`. This file provides a mapping from the old type name to the new type name. If you need to move forward without modifying your code, you can include this file in your project to provide declarations for the old type names.

## Changes to Events

- The `tapCount` field has been added to the [EventType](#) structure. The `tapCount` field specifies the number of times the user tapped the pen at the current location; in fields, two taps selects a word, and three taps selects a line.

## Compatibility Guide

### 3.5 New Feature Set

---

---

**IMPORTANT:** Because the `tapCount` field has been added to the `EventType` structure, it has become more critical that you clear the event structure before using it to add a new event to the queue. Otherwise, the `tapCount` will be incorrect for the new event.

---

- The structures for [ctlRepeatEvent](#) and [ctlSelectEvent](#) have a `value` field added to them. This new field is used only for sliders; it holds the current value of the slider.
- Form objects now handle the [frmTitleSelectEvent](#) by adding a [keyDownEvent](#) with the `vchrMenu` character to the event queue (which causes the form's menu to display).
- Some of the structure definitions for system-level events have moved from `Event.h` to `SysEvent.h`.
- The [winEnterEvent](#) is now not generated until [FrmDrawForm](#) is called. Make sure to draw your form in response to [frmOpenEvent](#), not `winEnterEvent`.
- [EvtSetNullEventTick](#) is now a function. In previous releases it was a macro.

## Other Changes

- [FrmDrawForm](#)

On release 3.5, `FrmDrawForm` erases the window's rectangle before it draws, so you must perform custom drawing after the call to `FrmDrawForm`, not before. If you have drawn before the call to `FrmDrawForm`, your changes are lost. On debug ROMs, the window handle is invalid until `FrmDrawForm` is called so that draws before `FrmDrawForm` result in a bus error.
- Resource Manager

The resource manager functions have been updated to work with overlay databases. See “[Using Overlays to Localize Resources](#)” on page 365 of the *Palm OS Programmer's Companion*, vol. I.

- [DmGetDatabase](#)

The order in which this call returns databases has changed. Previously all of the databases from ROM were returned first, then all from RAM. Now they are intermingled. Developers should not rely on the order in which databases are returned from this call.

- [StrToLower](#)

This function is different in 3.5 Latin ROMs. Previously it only changed A through Z. Now it also changes high ASCII characters.

- [Time Manager](#)

If you are using a debug ROM, the string buffer is filled with `dateStringLength` or `longStringLength` debugging bytes, depending on the `dateFormat` parameter. For the routines that return the day-of-week name in addition to the date, the size of the buffers has been expanded, so developers need to check the max lengths defined in `DateTime.h`.

- The format of the storage heap header has changed, thus any existing saved Simulator card images are invalid and should be tossed.

- [Category Data Structures](#)

The data structure [AppInfoType](#) has been documented.

[CategoryCreateList](#) now has a “hide” function with two new constants; `categoryHideEditCategory`, and `categoryDefaultEditCategoryString`.

- [FtrPtrNew](#)

`FtrPtrNew` now allows allocating chunks larger than 64KB.

- Dynamic heap

The dynamic heap is now sized based on the amount of memory available to the system.

**Table B.1 Dynamic heap size**

| Device RAM Size                  | Heap Size |
|----------------------------------|-----------|
| $x < 2\text{MB}$                 | 64KB      |
| $2\text{MB} \leq x < 4\text{MB}$ | 128KB     |
| $x \geq 4\text{MB}$              | 256KB     |

## Notification Feature Set

You can check that this feature set is implemented by checking for the existence of the notification manager. You can check by calling [FtrGet](#) as follows:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumNotifyMgrVersion, &value);
```

If the notification manager is part of the system, the `value` parameter will be non-zero and the returned error should also be zero (for no error).

### Notification Manager

[SysNotifyBroadcast](#)                      [SysNotifyRegister](#)  
[SysNotifyBroadcastDeferred](#)      [SysNotifyUnregister](#)

To learn more about the notification manager, see the section “[Notifications](#)” on page 30 of the *Palm OS Programmer’s Companion*, vol. I.

## 4.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 4.0 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The `romVersion` parameter should be greater than or equal to `0x04003000`, which can be constructed using the `sysMakeROMVersion` macro:

`sysMakeROMVersion(4,0,0,sysROMStageRelease,0)`

## Launch Codes

This feature set adds the following launch codes:

[sysAppLaunchCmdAttention](#)  
[sysAppLaunchCmdExgGetData](#)  
[sysAppLaunchCmdExgPreview](#)

## Notifications

This feature set adds the following notifications:

[cncNotifyProfileEvent](#)  
[sysExternalConnectorAttachEvent](#)  
[sysExternalConnectorDetachEvent](#)  
[sysNotifyCardInsertedEvent](#)  
[sysNotifyCardRemovedEvent](#)  
[sysNotifyDBDeletedEvent](#)  
[sysNotifyDeleteProtectedEvent](#)  
[sysNotifyDeviceUnlocked](#)  
[sysNotifyGotUsersAttention](#)  
[sysNotifyHelperEvent](#)  
[sysNotifyLocaleChangedEvent](#)  
[sysNotifyNetLibIFMediaEvent](#)  
[sysNotifyRetryEnqueueKey](#)  
[sysNotifyVolumeMountedEvent](#)  
[sysNotifyVolumeUnmountedEvent](#)

## Functions

This feature set adds the following functions:

### Attention Manager

|                                             |                                             |
|---------------------------------------------|---------------------------------------------|
| <a href="#"><u>AttnDoSpecialEffects</u></a> | <a href="#"><u>AttnIndicatorEnable</u></a>  |
| <a href="#"><u>AttnForgetIt</u></a>         | <a href="#"><u>AttnIndicatorEnabled</u></a> |
| <a href="#"><u>AttnGetAttention</u></a>     | <a href="#"><u>AttnIterate</u></a>          |

For more information about the Telephony Manager, see [Chapter 10](#), “[Telephony Manager](#),” in *Palm OS Programmer’s Companion*, vol. II, *Communications*.

### Windows Manager

|                                    |                                    |
|------------------------------------|------------------------------------|
| <a href="#">WinGetPixelRGB</a>     | <a href="#">WinSetBackColorRGB</a> |
| <a href="#">WinSetForeColorRGB</a> | <a href="#">WinSetTextColorRGB</a> |

### Internationalization Functions

The following functions have been added to aid with creating localized applications:

|                                       |                                       |
|---------------------------------------|---------------------------------------|
| <a href="#">FntWCharWidth</a>         | <a href="#">OmGetNextSystemLocale</a> |
| <a href="#">StrCompareAscii</a>       | <a href="#">TxtConvertEncoding</a>    |
| <a href="#">TxtGetWordWrapOffset</a>  | <a href="#">TxtNameToEncoding</a>     |
| <a href="#">IntlSetRoutineAddress</a> |                                       |

## Existing Functions that Changed

The following functions that existed prior to 4.0 have changed in release 4.0:

[ExgRegisterData](#) has been deprecated. The preferred function is now [ExgRegisterDatatype](#).

[ExgGet](#) was previously unimplemented. It has been implemented in release 4.0

[ExgNotifyReceive](#) was previously a private function. It is now a public function, intended to be used by exchange libraries.

[FldRecalculateField](#) now updates the word-wrapping information whenever `FldRecalculateField` is called, regardless of the value of the `redraw` parameter. Prior to Palm OS 4.0 it updated the word-wrapping information only if the `redraw` parameter was set to `true`.

[StrNCaselessCompare](#) now requires both of its string parameters to be null-terminated.

[StrNCompare](#) now requires both of its string parameters to be null-terminated.

## Expansion Manager Feature Set

Because not every system has (or needs) Expansion Manager services, applications wishing to use these services should check to make sure they are present before calling them. This is accomplished by checking for the Expansion Manager's system feature with a call to [FtrGet](#), supplying `sysFileCExpansionMgr` for the feature creator and `expFtrIDVersion` for the feature number.

The following code shows how to check for the presence and proper version of the Expansion Manger. Note that `expectedExpMgrVersionNum` should be replaced by the actual version number you expect.

```
UInt32 expMgrVersion;
Err err;

err = FtrGet(sysFileCExpansionMgr,
    expFtrIDVersion, &expMgrVersion);
if(err){
    // Expansion Manager not installed
} else {
    // check version number of Expansion Manager,
    // if necessary
    if(expMgrVersion == expectedExpMgrVersionNum)
        // everything is OK
}
```

---

You can learn more about the expansion manager by reading [Chapter 29, “Expansion Manager,”](#) on page 653.

## Functions

This feature set adds the following functions.

### Expansion Manager Functions

|                                      |                                     |
|--------------------------------------|-------------------------------------|
| <a href="#">ExpCardGetSerialPort</a> | <a href="#">ExpSlotDriverRemove</a> |
| <a href="#">ExpCardInfo</a>          | <a href="#">ExpSlotEnumerate</a>    |
| <a href="#">ExpCardPresent</a>       | <a href="#">ExpSlotLibFind</a>      |
| <a href="#">ExpSlotDriverInstall</a> |                                     |

## VFS Manager Feature Set

Because not every system has (or needs) Virtual File System (VFS) Manager services, applications wishing to use these services should check to make sure they are present before calling them. This is accomplished by checking for the VFS Manager’s system feature with a call to [FtrGet](#), supplying `sysFileCVFSMgr` for the feature creator and `vfsFtrIDVersion` for the feature number.

The following code shows how to check for the presence and proper version of the VFS Manger. Note that `expectedVFSMgrVersionNum` should be replaced by the actual version number you expect.

## Compatibility Guide

### VFS Manager Feature Set

---

---

```
UInt32 vfsMgrVersion;
Err err;

err = FtrGet(sysFileCVFSMgr,
    vfsFtrIDVersion, &vfsMgrVersion);
if(err){
    // VFS Manager not installed
} else {
    // check version number of VFS Manager,
    // if necessary
    if(vfsMgrVersion == expectedVFSMgrVersionNum)
        // everything is OK
}
```

---

You can learn more about the VFS manager by reading [Chapter 53](#), “[Virtual File System Manager](#),” on page 1075.

## Functions

This feature set adds the following functions.

### VFS Manager Functions

|                                               |                                                 |

## Bluetooth Library Feature Set

Because not every system has (or needs) Bluetooth Library services, applications wishing to use these services should check to make sure they are present before calling them. This is accomplished by checking for the Bluetooth Library's system feature with a call to [FtrGet](#), supplying `btLibFeatureCreator` for the feature creator and `btLibFeatureVersion` for the feature number.

The following code shows how to check for the presence of the Bluetooth Library.

---

```
UInt32 btVersion;

// Make sure Bluetooth components are installed
// This check also ensures Palm OS 4.0 or greater
if (FtrGet(btLibFeatureCreator, btLibFeatureVersion,
          &btVersion) != errNone) {
    // Alert the user if it's the active application
```

## Compatibility Guide

### Bluetooth Library Feature Set

---

```
    if ((launchFlags & sysAppLaunchFlagNewGlobals) &&
        (launchFlags & sysAppLaunchFlagUIApp))
        FrmAlert (MissingBtComponentsAlert);
    return sysErrRomIncompatible;
}
```

---

You can learn more about the Bluetooth Library by reading [Chapter 6, “Bluetooth,”](#) on page 131 of the *Palm OS Programmer’s Companion*, vol. II, *Communications*.

## Functions

This feature set adds the following functions.

## High-Density Display Feature Set

You can verify that this feature set is implemented by checking the version of the Window Manager. If the Window Manager version is 4 or greater, the High-Density Display feature set is supported. To check the version of the Window Manager, use this call:

```
err = FtrGet(sysFtrCreator,
            sysFtrNumWinVersion, &version);
```

Upon return, if `version` has a value of 4 or greater, the High-Density Display feature set is present. Note that just because the High-Density Display feature set is present, it isn't necessarily being used. You may want to check the density of the screen, as follows:

---

```
WinScreenGetAttribute(winScreenDensity, &attr);
if (attr == kDensityDouble) {
    //the screen is high density
}
```

---

The [5.0 New Feature Set](#) incorporates all of the functionality present in the High-Density Display Feature Set, so if your application is running on Palm OS 5 you can assume that the High-Density Display Feature Set is present as well.

## New Data Types

This feature set adds the following new data types.

### Bitmap Data Types

[BitmapTypeV0](#)

[BitmapTypeV1](#)

[BitmapTypeV2](#)

[BitmapTypeV3](#)

[DensityType](#)

[PixelFormatType](#)

In addition, the definition of [BitmapType](#) changed.

### Font Data Types

[FontDensityType](#)

[FontTypeV2](#)

In addition, this feature set defines a new [Extended Font Resource](#).

### Window Constants

This feature set adds a new set of [Window Coordinate System Constants](#).

## Functions

This feature set adds the following functions.

### Bitmap Functions

[BmpCreateBitmapV3](#)

[BmpGetCompressionType](#)

[BmpGetDensity](#)

[BmpGetNextBitmapAnyDensity](#)

[BmpGetTransparentValue](#)

[BmpGetVersion](#)

[BmpSetDensity](#)

[BmpSetTransparentValue](#)

## Compatibility Guide

### Sound Stream Feature Set

---

#### System Event Manager Functions

[EvtGetPenNative](#)

#### Window Functions

[WinGetCoordinateSystem](#)      [WinGetSupportedDensity](#)

[WinPaintRoundedRectangle](#)   [WinPaintTiledBitmap](#)  
[Frame](#)

[WinScaleCoord](#)                      [WinScalePoint](#)

[WinScaleRectangle](#)                [WinScreenGetAttribute](#)

[WinSetCoordinateSystem](#)        [WinUnscaleCoord](#)

[WinUnscalePoint](#)                    [WinUnscaleRectangle](#)

## Sound Stream Feature Set

The Sound Stream feature set adds a number of “stream” functions and constants to the Sound Manager. You can verify that this feature set is supported by checking for the Sound Manager’s version number. If the Sound Manager’s version feature is defined, the Sound Stream feature set is supported.

The following code shows how to check for the presence and proper version of the Sound Manger. Note that `expectedSndMgrVersionNum` should be replaced by the actual version number you expect (typically, `sndMgrVersionNum`).

---

```
UInt32 version;
Err err;

err = FtrGet(sysFileCSoundMgr, sndFtrIDVersion, &version);
if(err){
    // Sound Stream Feature Set not present
} else {
    // The Sound Stream Feature Set is present.
    // Check version number of Sound Manager,
    // if necessary
    if(version == expectedSndMgrVersionNum)
        // everything is OK
}
```

---

## 5.0 New Feature Set

You can check that this feature set is implemented by checking that the system version is 5.0 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The `romVersion` parameter should be greater than or equal to `0x05003000`, which can be constructed using the `sysMakeROMVersion` macro:

```
sysMakeROMVersion(5, 0, 0, sysROMStageRelease, 0)
```

This feature set corresponds to version 5.0 of Palm OS 5.

The Palm OS Application Compatibility Environment (PACE) has its own version associated with it. You can obtain this version number with:

```
err = FtrGet('pace', 0, &paceVersion);
```

### Notifications

This feature set adds the following database-related notifications:

[sysNotifyDBCreatedEvent](#)   [sysNotifyDBDirtyEvent](#)  
[sysNotifyDBChangedEvent](#)

It also broadcasts the following notifications:

[sysNotifyAppLaunchingEvent](#)  
[sysNotifyAppQuittingEvent](#)  
[sysNotifyEventDequeuedEvent](#)  
[sysNotifyIdleTimeEvent](#)  
[sysNotifyInsPtEnableEvent](#)  
[sysNotifyKeyboardDialogEvent](#)  
[sysNotifyProcessPenStrokeEvent](#)  
[sysNotifyVirtualCharHandlingEvent](#)

### Functions

This feature set adds the following functions.

## **ARM-Native Functions**

[PceNativeCall](#)

## **Functions and Traps not Supported by PACE**

For various reasons a number of functions and traps are not supported by PACE. The following sections list those functions, grouped according to the reason that they are not implemented.

### **Unimplemented “System Use Only” Functions**

The following functions, which are documented as “System Use Only,” are not supported by the Palm OS Application Compatibility Environment (PACE).

## Compatibility Guide

| MemPtrFlags                     | WinRemoveWindow          |
| MemPtrOwner                     |                          |

1. Implemented on release ROMs but flagged as illegal on debug ROMs.

As a rule, functions and traps that are not documented should be treated as if they are unimplemented and should not be used by applications.

### Implemented “System Use Only” Functions and Traps

Although marked “System Use Only,” a number of functions and traps are required by applications in the ROM, by Palm Debugger, by test applications, by scripting, or by some popular applications. Because of this, the following System Use Only functions and traps are supported by PACE. Because they are intended only for system use, however, applications should do what they can to avoid using them.

|                                           |                                   |
|-------------------------------------------|-----------------------------------|
| <code>AlmEnableNotification</code>        | <code>HwrDockStatus</code>        |
| <code>AttnAllowClose</code>               | <code>HwrLEDAttributes</code>     |
| <code>AttnEnableNotification</code>       | <code>HwrMemReadable</code>       |
| <code>AttnIndicatorAllow</code>           | <code>HwrMemWritable</code>       |
| <code>AttnIndicatorAllowed</code>         | <code>HwrVibrateAttributes</code> |
| <code>AttnIndicatorGetBlinkPattern</code> | <code>MemChunkNew</code>          |
| <code>AttnIndicatorSetBlinkPattern</code> | <code>MemHeapPtr</code>           |
| <code>AttnReopen</code>                   | <code>PenRawToScreen</code>       |
| <code>DmResetRecordStates</code>          | <code>PenScreenToRaw</code>       |
| <code>EvtEnqueuePenPoint</code>           | <code>SysGetAppInfo</code>        |
| <code>EvtGetSilkscreenAreaList</code>     | <code>SysLaunchConsole</code>     |
| <code>FileReadLow</code>                  | <code>SndSetDefaultVolume</code>  |
| <code>Find</code>                         | <code>SysLCDContrast</code>       |
| <code>FrmActiveState</code>               | <code>SysSetA5</code>             |
| <code>FrmHandleEvent</code>               | <code>SysSetPerformance</code>    |
| <code>HwrDelay</code>                     | <code>SysSleep</code>             |
|                                           | <code>SysUIBusy</code>            |
|                                           | <code>WinDrawWindowFrame</code>   |

### Obsolete Functions and Traps

The following functions are not supported by PACE because they are obsolete.

|                                                          |                                                         |
|----------------------------------------------------------|---------------------------------------------------------|
| <code><a href="#">FplAdd</a><sup>1</sup></code>          | <code><a href="#">FplFToA</a><sup>1</sup></code>        |
| <code><a href="#">FplAToF</a><sup>1</sup></code>         | <code><a href="#">FplLongToFloat</a><sup>1</sup></code> |
| <code><a href="#">FplBase10Info</a><sup>1</sup></code>   | <code><a href="#">FplMul</a><sup>1</sup></code>         |
| <code><a href="#">FplDiv</a><sup>1</sup></code>          | <code><a href="#">FplSub</a><sup>1</sup></code>         |
| <code><a href="#">FplFloatToLong</a><sup>1</sup></code>  | <code>WiCmdV32</code>                                   |
| <code><a href="#">FplFloatToULong</a><sup>1</sup></code> |                                                         |

1. Implemented on release ROMs but flagged as illegal on debug ROMs.

## Compatibility Guide

### 5.0 New Feature Set

---

#### 'NOP' Functions and Traps

These functions and traps should not be called by applications (many are documented as "System Use Only"). Because some third-party applications do call them, for backward compatibility they act as NOPs.

|                         |                     |
|-------------------------|---------------------|
| <a href="#">FplFree</a> | SerReceiveISP       |
| <a href="#">FplInit</a> | SrmSleep            |
| HwrEnableDataWrites     | SrmWake             |
| HwrDisableDataWrites    | SysDisableInts      |
| HwrTimerSleep           | SysRestoreStatus    |
| HwrTimerWake            | TimHandleInterrupt  |
| KeyResetDoubleTap       | TimSleep            |
| KeySleep                | TimWake             |
| KeyWake                 | WinDisableWindow    |
| PenSleep                | WinEnableWindow     |
| PenWake                 | WinInitializeWindow |

#### Unimplemented Rare Functions and Traps

These functions and traps are only used internally by Palm OS, by serial drivers, by OEM extensions, and the like. They are not implemented by PACE.

|                                    |                                       |
|------------------------------------|---------------------------------------|
| ConGetS                            | FlashErase                            |
| ConPutS                            | FlashProgram                          |
| <a href="#">DayDrawDays</a>        | <a href="#">IntlSetRoutineAddress</a> |
| <a href="#">DayDrawDaySelector</a> | MemGetRomNVParams                     |
| DbgCommSettings                    | MemNVParams                           |
| DbgGetMessage                      | OEMDispatch <sup>1</sup>              |
| DlkDispatchRequest                 | <a href="#">ResLoadForm</a>           |
| DlkStartServer                     | <a href="#">SlkSetSocketListener</a>  |
| DmMoveOpenDBContext                | SysNotifyDatabaseAdded                |
| DmOpenDBWithLocale                 | SysNotifyDatabaseRemoved              |
| FlashCompress                      | <a href="#">SysSetTrapAddress</a>     |

1. Supported if the OEM supports the trap.

## 5.1 New Feature Set

You can check that this feature set is implemented by checking that the system version is 5.1 or higher. Use this [FtrGet](#) call:

```
err = FtrGet(sysFtrCreator,  
            sysFtrNumROMVersion, &romVersion);
```

The `romVersion` parameter should be greater than or equal to `0x05103000`, which can be constructed using the `sysMakeROMVersion` macro:

```
sysMakeROMVersion(5, 1, 0, sysROMStageRelease, 0)
```

This feature set corresponds to version 5.1 of Palm OS 5.

### Net Library Interface Settings

This feature set adds the following Net Library Interface Settings:

|                              |                                     |
|------------------------------|-------------------------------------|
| <code>DriverVersion</code>   | <code>80211AccessPointBSSID</code>  |
| <code>FirmwareVersion</code> | <code>80211AssociationStatus</code> |
| <code>FirmwareDate</code>    | <code>80211MKKCallSign</code>       |
| <code>80211Device</code>     | <code>80211CountryTest</code>       |
| <code>80211ESSID</code>      |                                     |

See [NetLibIFSettingGet](#) for a description of each of the above settings.

### CPM Library

This feature set includes the Cryptographic Provider Manager (CPM) shared library. The CPM library isn't automatically loaded upon system boot: before making use of the CPM library you must first load it, using `SysLibFind` and `SysLibLoad`.

The CPM library defines a number of constants:

- [AP Capability Constants](#)
- [Block Encryption Mode Constants](#)
- [Cipher Algorithm Constants](#)
- [Export Encoding Constants](#)
- [Hashing Algorithm Constants](#)

## Compatibility Guide

### 5.1 New Feature Set

---

- [Key Class Constants](#)
- [Key Usage Constants](#)
- [Plaintext Padding Constants](#)

The following structures are defined as part of the CPM library:

|                                         |                                      |
|-----------------------------------------|--------------------------------------|
| <a href="#">APCipherInfoStruct</a>      | <a href="#">APProviderInfoStruct</a> |
| <a href="#">APHashInfoStruct</a>        | <a href="#">APVerifyInfoStruct</a>   |
| <a href="#">APKeyInfoStruct</a>         | <a href="#">CPMInfoStruct</a>        |
| <a href="#">APProviderContextStruct</a> |                                      |

Finally, the CPM library contains the following functions:

|                                        |                                         |
|----------------------------------------|-----------------------------------------|
| <a href="#">CPMLibDecrypt</a>          | <a href="#">CPMLibHash</a>              |
| <a href="#">CPMLibDecryptFinal</a>     | <a href="#">CPMLibHashFinal</a>         |
| <a href="#">CPMLibDecryptInit</a>      | <a href="#">CPMLibHashInit</a>          |
| <a href="#">CPMLibDecryptUpdate</a>    | <a href="#">CPMLibImportCipherInfo</a>  |
| <a href="#">CPMLibEncrypt</a>          | <a href="#">CPMLibImportHashInfo</a>    |
| <a href="#">CPMLibEncryptFinal</a>     | <a href="#">CPMLibImportKeyInfo</a>     |
| <a href="#">CPMLibEncryptInit</a>      | <a href="#">CPMLibImportVerifyInfo</a>  |
| <a href="#">CPMLibEncryptUpdate</a>    | <a href="#">CPMLibReleaseCipherInfo</a> |
| <a href="#">CPMLibExportCipherInfo</a> | <a href="#">CPMLibReleaseHashInfo</a>   |
| <a href="#">CPMLibExportHashInfo</a>   | <a href="#">CPMLibReleaseKeyInfo</a>    |

| <a href="#">CPMLibGetProviderInfo</a>  | <a href="#">CPMLibVerifyUpdate</a>      |

## SSL Library

The 5.1 New Feature Set includes the Secure Sockets Layer (SSL) shared library. The SSL library isn't automatically loaded upon system boot: before making use of the SSL library you must first load it and open it, using code similar to the following:

---

```
Err error;
UInt16 libRef;

if ( SysLibFind( kSslDBName, &libRef ) != 0 )
{
    error = SysLibLoad(kSslLibType, kSslLibCreator, &libRef);
}
```

```
/* error checking goes here. */  
error = SslLibOpen( libRef );  
...
```

---

## SSL Library Structures and Data Types

The SSL library defines a number of structures and data types:

|                                    |                                  |
|------------------------------------|----------------------------------|
| <a href="#">SslAttribute</a>       | <a href="#">SslExtendedItems</a> |
| <a href="#">SslContext</a>         | <a href="#">SslIoBuf</a>         |
| <a href="#">SslLib</a>             | <a href="#">SslLibCallback</a>   |
| <a href="#">SslCallback</a>        | <a href="#">SslSession</a>       |
| <a href="#">SslCipherSuiteInfo</a> | <a href="#">SslSocket</a>        |
| <a href="#">SslExtendedItem</a>    | <a href="#">SslVerify</a>        |

## SSL Library Functions

|                                   |                               |
|-----------------------------------|-------------------------------|
| <a href="#">SslClose</a>          | <a href="#">SslLibOpen</a>    |
| <a href="#">SslConsume</a>        | <a href="#">SslLibGetLong</a> |
| <a href="#">SslContextCreate</a>  | <a href="#">SslLibGetPtr</a>  |
| <a href="#">SslContextDestroy</a> | <a href="#">SslLibSetLong</a> |
| <a href="#">SslContextGetLong</a> | <a href="#">SslLibSetPtr</a>  |
| <a href="#">SslContextGetPtr</a>  | <a href="#">SslOpen</a>       |
| <a href="#">SslContextSetLong</a> | <a href="#">SslPeek</a>       |
| <a href="#">SslContextSetPtr</a>  | <a href="#">SslRead</a>       |
| <a href="#">SslFlush</a>          | <a href="#">SslReceive</a>    |
| <a href="#">SslLibClose</a>       | <a href="#">SslSend</a>       |
| <a href="#">SslLibCreate</a>      | <a href="#">SslWrite</a>      |
| <a href="#">SslLibDestroy</a>     |                               |

In addition, the SSL library defines one callback function:

- [SslCallbackFunc](#)

## SSL Library Attributes and Macros

You interact with SSL attributes using the following macros:

- [SslContextGet\\_Attribute \(integer version\)](#)
- [SslContextGet\\_Attribute \(pointer version\)](#)
- [SslLibSet\\_Attribute \(integer version\)](#)
- [SslContextSet\\_Attribute \(pointer version\)](#)

## Compatibility Guide

### 5.1 New Feature Set

---

- [SslLibGet\\_Attribute \(integer version\)](#)
- [SslLibGet\\_Attribute \(pointer version\)](#)
- [SslLibSet\\_Attribute \(integer version\)](#)
- [SslLibSet\\_Attribute \(pointer version\)](#)

The attributes that you can manipulate with the above macros are:

|                                     |                                 |
|-------------------------------------|---------------------------------|
| <a href="#">AppInt32</a>            | <a href="#">LastIO</a>          |
| <a href="#">AppPtr</a>              | <a href="#">Mode</a>            |
| <a href="#">AutoFlush</a>           | <a href="#">PeerCert</a>        |
| <a href="#">BufferedReuse</a>       | <a href="#">PeerCommonName</a>  |
| <a href="#">CipherSuite</a>         | <a href="#">ProtocolVersion</a> |
| <a href="#">CipherSuiteInfo</a>     | <a href="#">RbufSize</a>        |
| <a href="#">CipherSuites</a>        | <a href="#">ReadBufPending</a>  |
| <a href="#">Compat</a>              | <a href="#">ReadOutstanding</a> |
| <a href="#">DontSendShutdown</a>    | <a href="#">ReadRecPending</a>  |
| <a href="#">DontWaitForShutdown</a> | <a href="#">ReadStreaming</a>   |
| <a href="#">Error</a>               | <a href="#">SessionReused</a>   |
| <a href="#">HsState</a>             | <a href="#">Socket</a>          |
| <a href="#">InfoCallback</a>        | <a href="#">SslSession</a>      |
| <a href="#">InfoInterest</a>        | <a href="#">SslVerify</a>       |
| <a href="#">IoTimeout</a>           | <a href="#">Streaming</a>       |
| <a href="#">IoFlags</a>             | <a href="#">VerifyCallback</a>  |
| <a href="#">IoStruct</a>            | <a href="#">WbufSize</a>        |
| <a href="#">LastAlert</a>           | <a href="#">WriteBufPending</a> |
| <a href="#">LastApi</a>             |                                 |

# 1.0 Float Manager

---

This section provides reference material for the Palm OS 1.0 float manager. In Palm OS 1.0, the float manager API is declared in the header file `FloatMgr.h`. In Palm OS 2.0, this file was renamed to `FloatMgrOld.h`. In Palm OS 3.5, this file was made private.

---

**NOTE:** New applications should no longer use the 1.0 Float Manager. See [Chapter 32, “Float Manager,”](#) on page 695 for the functions now provided by the Float Manager.

---

## Float Manager Functions

### FplAdd

|                      |                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Add two floating-point numbers (returns $a + b$ ).                                                                                                                                                                   |
| <b>Prototype</b>     | <code>FloatType FplAdd (FloatType a, FloatType b)</code>                                                                                                                                                             |
| <b>Parameters</b>    | <code>a, b</code> The floating-point numbers.                                                                                                                                                                        |
| <b>Result</b>        | Returns the normalized floating-point result of the addition.                                                                                                                                                        |
| <b>Comments</b>      | Under Palm OS <sup>®</sup> 2.0 and later, most applications will want to use the arithmetic symbols instead. See the <a href="#">“Floating-Point”</a> section in the <i>Palm OS Programmer’s Companion</i> , vol. I. |
| <b>Compatibility</b> | This function is not supported by PACE ( <a href="#">5.0 New Feature Set</a> ).                                                                                                                                      |

## 1.0 Float Manager

### Float Manager Functions

---

#### FplAToF

- Purpose** Convert a zero-terminated ASCII string to a floating-point number. The string must be in the format: [-]x[.]yyyyyyyy[e[-]zz]
- Prototype** `FloatType FplAToF (char* s)`
- Parameters** `s` Pointer to the ASCII string.
- Result** Returns the floating-point number.
- Comments** The mantissa of the number is limited to 32 bits.
- Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).
- See Also** [FplFToA](#), [FplFree](#), [FplInit](#)

#### FplBase10Info

- Purpose** Extract detailed information on the base 10 form of a floating-point number: the base 10 mantissa, exponent, and sign.
- Prototype** `Err FplBase10Info (FloatType a, ULong* mantissaP, Int* exponentP, Int* signP)`
- Parameters**
- |                        |                                      |
|------------------------|--------------------------------------|
| <code>a</code>         | The floating-point number.           |
| <code>mantissaP</code> | The base 10 mantissa (return value). |
| <code>exponentP</code> | The base 10 exponent (return value). |
| <code>signP</code>     | The sign, 1 or -1 (return value).    |
- Result** Returns an error code, or 0 if no error.
- Comments** The mantissa is normalized so it contains at least `kMaxSignificantDigits` significant digits when printed as an integer value.

FlpBase10Info reports that zero is "negative"; that is, it returns a one for xSign. If this is a problem, a simple workaround is:

```
if (xMantissa == 0) {  
    xSign = 0;  
}
```

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

## **FplDiv**

**Purpose** Divide two floating-point numbers (result = dividend/divisor).

**Prototype** `FloatType FplDiv (FloatType dividend,  
FloatType divisor)`

**Parameters**

|          |                          |
|----------|--------------------------|
| dividend | Floating-point dividend. |
| divisor  | Floating-point divisor.  |

**Result** Returns the normalized floating-point result of the division.

Under Palm OS 2.0 and later, most applications will want to use the arithmetic symbols instead. See the "[Floating-Point](#)" section in the *Palm OS Programmer's Companion*, vol. I.

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

## **FplFloatToLong**

**Purpose** Convert a floating-point number to a long integer.

**Prototype** `Long FplFloatToLong (FloatType f)`

**Parameters**

|   |                                        |
|---|----------------------------------------|
| f | Floating-point number to be converted. |
|---|----------------------------------------|

**Result** Returns the long integer.

## 1.0 Float Manager

### Float Manager Functions

---

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

**See Also** [FplLongToFloat](#), [FplFloatToULong](#)

### FplFloatToULong

**Purpose** Convert a floating-point number to an unsigned long integer.

**Prototype** `ULong FplFloatToULong (FloatType f)`

**Parameters** `f` Floating-point number to be converted.

**Result** Returns an unsigned long integer.

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

**See Also** [FplLongToFloat](#), [FplFloatToLong](#)

### FplFree

**Purpose** Release all memory allocated by the floating-point initialization.

**Prototype** `void FplFree()`

**Parameters** None.

**Result** Returns nothing.

**Comments** Applications must call this routine after they've called other functions that are part of the float manager.

**Compatibility** If [5.0 New Feature Set](#) is present, this function acts as a NOP.

**See Also** [FplInit](#)

## **FplFToA**

- Purpose** Convert a floating-point number to a zero-terminated ASCII string in exponential format: [-]x.yyyyyyye[-]zz
- Prototype** `Err FplFToA (FloatType a, char* s)`
- Parameters**
- |   |                                                |
|---|------------------------------------------------|
| a | Floating-point number.                         |
| s | Pointer to buffer to contain the ASCII string. |
- Result** Returns an error code, or 0 if no error.
- Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).
- See Also** [FplAToF](#), [FplFree](#), [FplInit](#)

## **FplInit**

- Purpose** Initialize the floating-point conversion routines.  
Allocate space in the system heap for floating-point globals.  
Initialize the `tenPowers` array in the globals area to the powers of 10 from -99 to +99 in floating-point format.
- Prototype** `Err FplInit()`
- Parameters** None.
- Result** Returns an error code, or 0 if no error.
- Comments** Applications must call this routine before calling any other `Fpl` function.
- Compatibility** If [5.0 New Feature Set](#) is present, this function acts as a NOP.
- See Also** [FplFree](#)

## 1.0 Float Manager

### Float Manager Functions

---

#### FplLongToFloat

- Purpose** Convert a long integer to a floating-point number.
- Prototype** `FloatType FplLongToFloat (Long x)`
- Parameters** `x` A long integer.
- Result** Returns the floating-point number.
- Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

#### FplMul

- Purpose** Multiply two floating-point numbers.
- Prototype** `FloatType FplMul (FloatType a, FloatType b)`
- Parameters** `a, b` The floating-point numbers.
- Result** Returns the normalized floating-point result of the multiplication.
- Comments** Under Palm OS 2.0 and later, most applications will want to use the arithmetic symbols instead. See the [“Floating-Point”](#) section in the *Palm OS Programmer’s Companion*, vol. I.
- Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).

#### FplSub

- Purpose** Subtract two floating-point numbers (returns  $a - b$ ).
- Prototype** `FloatType FplSub (FloatType a, FloatType b)`
- Parameters** `a, b` The floating-point numbers.
- Result** Returns the normalized floating-point result of the subtraction.

**Comments** Under Palm OS 2.0 and later, most applications will want to use the arithmetic symbols instead. See the [“Floating-Point”](#) section in the *Palm OS Programmer’s Companion*, vol. I.

**Compatibility** This function is not supported by PACE ([5.0 New Feature Set](#)).
