# About This Document

---

*Palm OS Programmer's API Reference* is part of the Palm OS® Software Development Kit. This introduction provides an overview of SDK documentation, discusses what materials are included in this document, and what conventions are used.

## Palm OS SDK Documentation

The following documents are part of the SDK:

Document	Description
<i>Palm OS Programmer's API Reference</i>	An API reference document that contains descriptions of all Palm OS function calls and important data structures.
<i>Palm OS Programmer's Companion</i>	A multi-volume guide to application programming for the Palm OS. This guide contains conceptual and "how-to" information that complements the Reference.
<i>Constructor for Palm OS</i>	A guide to using Constructor to create Palm OS resource files.
<i>Palm OS Programming Development Tools Guide</i>	A guide to writing and debugging Palm OS applications with the various tools available.

## What This Volume Contains

This section provides an overview of this volume.

- Part I, "User Interface," documents the API contained in the header files in the `\Incs\Core\UI\` folder. This part contains chapters covering subjects such as application launch codes, user interface resources, events, and all window, form, and field object managers.

## About This Document

### *Additional Resources*

---

- Part II, “System Management,” documents the API contained in the header files in the `\Incs\Core\System\` folder. This part contains chapters covering subjects such as the alarm manager, data and resource manager, feature manager, float manager, graffiti manager, key manager, memory manager, preferences manager, sound manager, string manager, and system manager.
- Part III, “Communications,” documents the API related to communications, such as the exchange manager, IR library, net library, Secure Sockets Layer (SSL) library, serial manager, and serial drivers.
- Part IV, “Libraries,” documents the API contained in the header files in the `\Incs\Libraries\` folder. This part contains chapters covering the Internet Library and the Palm OS Glue library.

## Additional Resources

- Documentation  
PalmSource publishes its latest versions of this and other documents for Palm OS developers at  
<http://www.palmos.com/dev/support/docs/>
- Training  
PalmSource and its partners host training classes for Palm OS developers. For topics and schedules, check  
<http://www.palmos.com/dev/training>
- Knowledge Base  
The Knowledge Base is a fast, web-based database of technical information. Search for frequently asked questions (FAQs), sample code, white papers, and the development documentation at  
<http://www.palmos.com/dev/support/kb/>

## Conventions Used in This Guide

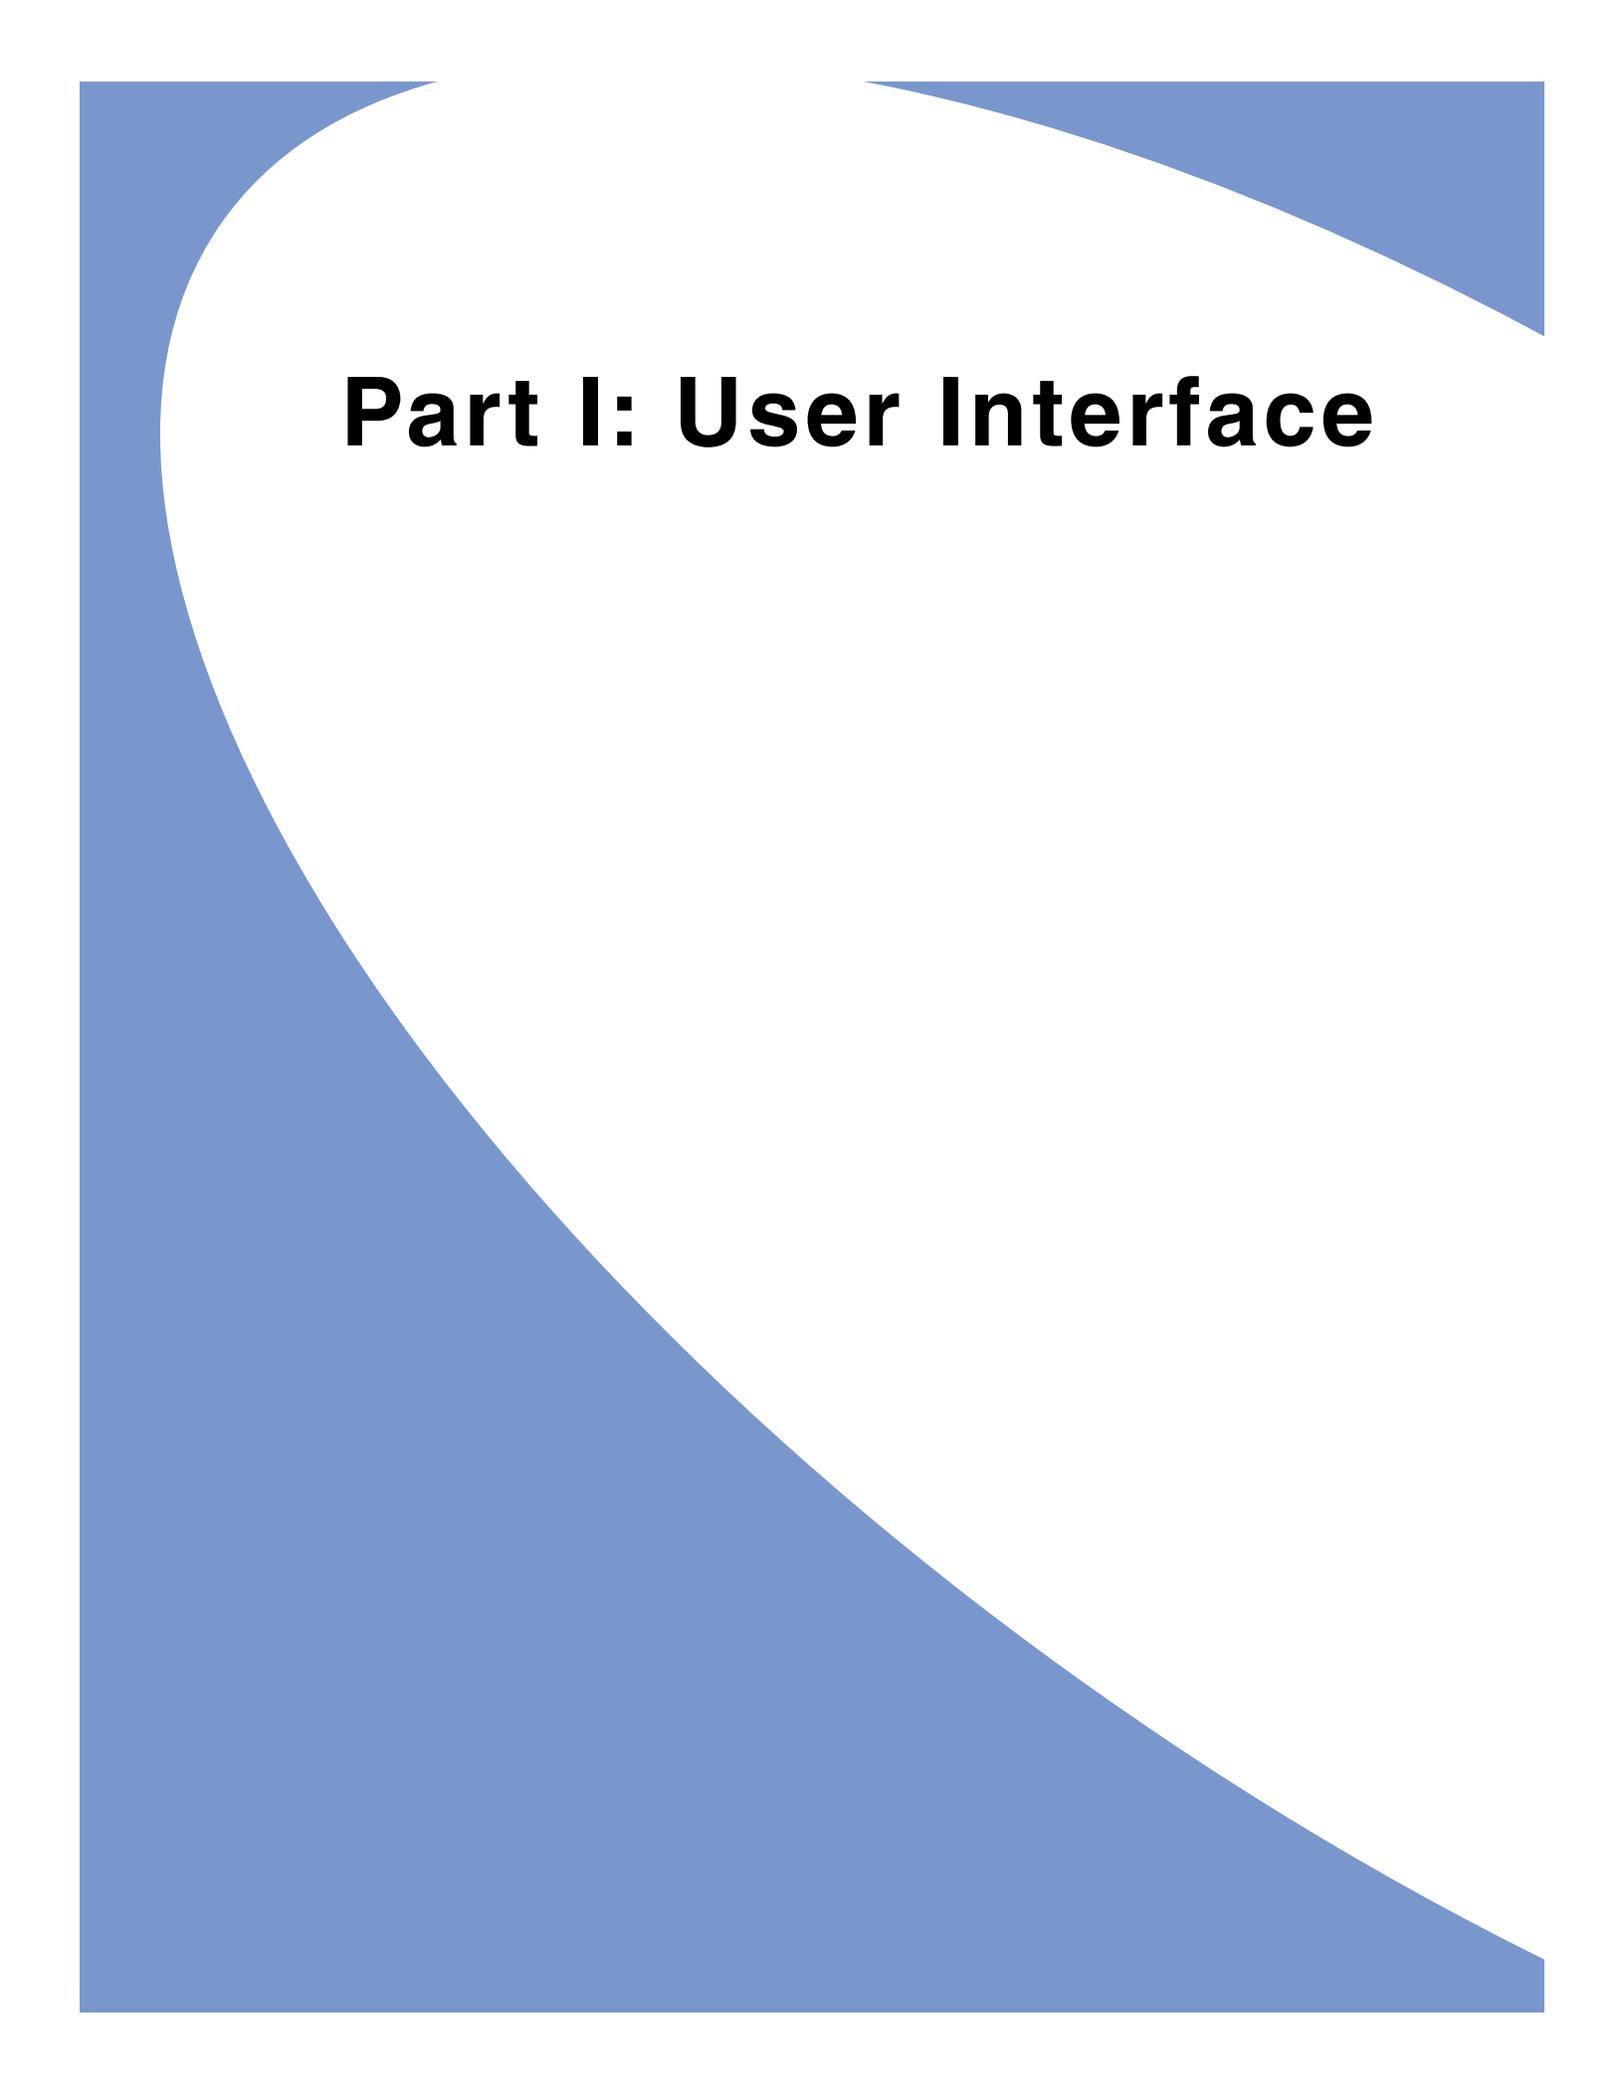

This guide uses the following typographical conventions:

<b>This style...</b>	<b>Is used for...</b>
<code>fixed width font</code>	Code elements such as function, structure, field, bitfield.
<i>italic</i>	Emphasis (for other elements).
<a href="#"><u>blue and underlined</u></a>	Hot links.

## **About This Document**

*Conventions Used in This Guide*

---

# **Part I: User Interface**

# Application Launch Codes

---

This chapter provides detailed information about the predefined application launch codes. Launch codes are declared in the header file `SystemMgr.h`. The associated parameter blocks are declared in `AppLaunchCmd.h`, `AlarmMgr.h`, `ExgMgr.h`, and `Find.h`.

[Table 1.1](#) lists all Palm OS® standard launch codes. More detailed information is provided immediately after the table:

- [Launch Codes](#)
- [Launch Flags](#)

To learn what a launch code is and how to use it, see the chapter titled “[Application Startup and Stop](#)” in the *Palm OS Programmer’s Companion*, vol. I.

**Table 1.1 Palm OS Launch Codes**

Code	Request
<a href="#">scptLaunchCmdExecuteCmd</a>	Execute the specified Network login script plugin command.
<a href="#">scptLaunchCmdListCmds</a>	Provide information about the commands that your Network script plugin executes.
<a href="#">sysAppLaunchCmdAddRecord</a>	Add a record to a database.
<a href="#">sysAppLaunchCmdAlarmTriggered</a>	Schedule next alarm or perform quick actions such as sounding alarm tones.
<a href="#">sysAppLaunchCmdAttention</a>	Perform the action requested by the attention manager.

## Application Launch Codes

---

Table 1.1 Palm OS Launch Codes (*continued*)

Code	Request
<a href="#"><u>sysAppLaunchCmdCardLaunch</u></a>	Launch the application. This launch code signifies that the application is being launched from an expansion card.
<a href="#"><u>sysAppLaunchCmdCountryChange</u></a>	Respond to country change.
<a href="#"><u>sysAppLaunchCmdDisplayAlarm</u></a>	Display specified alarm dialog or perform time-consuming alarm-related actions.
<a href="#"><u>sysAppLaunchCmdExgAskUser</u></a>	Let application override display of dialog asking user if they want to receive incoming data via the Exchange Manager.
<a href="#"><u>sysAppLaunchCmdExgGetData</u></a>	Notify application that it should send data using the Exchange Manager.
<a href="#"><u>sysAppLaunchCmdExgPreview</u></a>	Notify application that it should display a preview using the Exchange Manager.
<a href="#"><u>sysAppLaunchCmdExgReceiveData</u></a>	Notify application that it should receive incoming data using the Exchange Manager.
<a href="#"><u>sysAppLaunchCmdFind</u></a>	Find a text string.
<a href="#"><u>sysAppLaunchCmdGoto</u></a>	Go to a particular record, display it, and optionally select the specified text.
<a href="#"><u>sysAppLaunchCmdGoToURL</u></a>	Launch an application and open a URL.
<a href="#"><u>sysAppLaunchCmdHandleSyncCallApp</u></a>	Perform some application-specific operation at the behest of the application's conduit.
<a href="#"><u>sysAppLaunchCmdInitDatabase</u></a>	Initialize database.

**Table 1.1 Palm OS Launch Codes (*continued*)**

Code	Request
<a href="#"><u>sysAppLaunchCmdLookup</u></a>	Look up data. In contrast to <code>sysAppLaunchCmdFind</code> , a level of indirection is implied. For example, look up a phone number associated with a name.
<code>sysAppLaunchCmdNormalLaunch</code>	Launch normally.
<a href="#"><u>sysAppLaunchCmdNotify</u></a>	Notify about an event.
<a href="#"><u>sysAppLaunchCmdOpenDB</u></a>	Launch application and open a database.
<a href="#"><u>sysAppLaunchCmdPanelCalledFromApp</u></a>	Tell preferences panel that it was invoked from an application, not the Preferences application.
<a href="#"><u>sysAppLaunchCmdReturnFromPanel</u></a>	Tell an application that it's restarting after preferences panel had been called.
<a href="#"><u>sysAppLaunchCmdSaveData</u></a>	Save data. Often sent before find operations.
<a href="#"><u>sysAppLaunchCmdSyncNotify</u></a>	Notify applications that a HotSync <sup>®</sup> has been completed.
<a href="#"><u>sysAppLaunchCmdSystemLock</u></a>	Sent to the Security application to request that the system be locked down.
<a href="#"><u>sysAppLaunchCmdSystemReset</u></a>	Respond to system reset. No UI is allowed during this launch code.
<a href="#"><u>sysAppLaunchCmdTimeChange</u></a>	Respond to system time change.
<a href="#"><u>sysAppLaunchCmdURLParams</u></a>	Launch an application with parameters from the Web Clipping Application Viewer.

# Launch Codes

This section provides supplemental information about launch codes. For some launch codes, it lists the parameter block, which in some cases provides additional information about the launch code.

## sysAppLaunchCmdAddRecord

Add a record to an application's database.

This launch code is used to add a message to the Mail or iMessenger™ (on the Palm VII™ organizer) application's outbox. You pass information about the message such as address, body text, etc. in the parameter block. For iMessenger, you can set the `edit` field of the parameter block to control whether or not the iMessenger editor is displayed. Set it to `true` to display the editor or `false` not to display it.

For more information on sending messages via iMessenger, see "[Sending Email Messages](#)" on page 210 in the *Palm OS Programmer's Companion*, vol. II, *Communications*.

---

**IMPORTANT:** Implemented for iMessenger only if [Wireless Internet Feature Set](#) is present. Implemented for Mail only on OS version 3.0 or later.

---

## sysAppLaunchCmdAddRecord Parameter Block for Mail Application

**Prototype**

```
typedef enum {
    mailPriorityHigh,
    mailPriorityNormal,
    mailPriorityLow
} MailMsgPriorityType;

typedef struct {
    Boolean secret;
    Boolean signature;
    Boolean confirmRead;
    Boolean confirmDelivery;
    MailMsgPriorityType priority;
    UInt8 padding;
    Char* subject;
```

```
Char* from;  
Char* to;  
Char* cc;  
Char* bcc;  
Char* replyTo;  
Char* body;  
} MailAddRecordParamsType;
```

<b>Fields</b>	<code>secret</code>	True means that the message should be marked secret.
	<code>signature</code>	True means that the signature from the Mail application's preferences should be attached to the message.
	<code>confirmRead</code>	True means that a confirmation should be sent when the message is read.
	<code>confirmDelivery</code>	True means that a confirmation should be sent when the message is delivered.
	<code>priority</code>	Message priority. Specify one of the <code>MailMsgPriorityType</code> enumerated types.
	<code>padding</code>	Reserved for future use.
	<code>subject</code>	Message's subject, a null-terminated string (optional).
	<code>from</code>	Message's sender, a null-terminated string (not used on outgoing mail).
	<code>to</code>	Address of the recipient, a null-terminated string (required).
	<code>cc</code>	Addresses of recipients to be copied, a null-terminated string (optional).
	<code>bcc</code>	Addresses of recipients to be blind copied, a null-terminated string (optional).
	<code>replyTo</code>	Reply to address, a null-terminated string (optional).
	<code>body</code>	The text of the message, a null-terminated string (required).

## Application Launch Codes

### Launch Codes

---

#### sysAppLaunchCmdAddRecord Parameter Block for iMessenger Application

**Prototype**

```
typedef struct {
    UInt16 category;
    Boolean edit;
    Boolean signature;
    Char *subject;
    Char *from;
    Char *to;
    Char *replyTo;
    Char *body;
} MsgAddRecordParamsType;
```

<b>Fields</b>	<b>category</b>	Category in which to place the message. Specify one of the following categories:  MsgInboxCategory  MsgOutboxCategory  MsgDeletedCategory  MsgFiledCategory  MsgDraftCategory
	<b>edit</b>	True means that the message should be opened in the editor. False means that the message should simply be placed into the outbox and the editor not opened. You can specify true only if the category is set to MsgOutboxCategory.
	<b>signature</b>	True means that the signature from the iMessenger application preferences should be attached to the message.
	<b>subject</b>	Message's subject, a null-terminated string (optional).
	<b>from</b>	Message's sender, a null-terminated string (not used on outgoing mail).
	<b>to</b>	Address of the recipient, a null-terminated string (required).

replyTo	Reply to address, a null-terminated string (optional).
body	The text of the message, a null-terminated string (required).

## sysAppLaunchCmdAlarmTriggered

Performs quick action such as scheduling next alarm or sounding alarm.

This launch code is sent as close to the actual alarm time as possible. An application may perform any quick, non-blocking action at this time. Multiple alarms may be pending at the same time for multiple applications, and one alarm display shouldn't block the system and prevent other applications from receiving their alarms in a timely fashion. An opportunity to perform more time-consuming actions will come when [sysAppLaunchCmdDisplayAlarm](#) is sent.

### sysAppLaunchCmdAlarmTriggered Parameter Block

**Prototype**

```
typedef struct SysAlarmTriggeredParamType {
    UInt32      ref;
    UInt32      alarmSeconds;
    Boolean      purgeAlarm;
    UInt8       padding;
} SysAlarmTriggeredParamType;
```

<b>Fields</b>	-> ref	The caller-defined value specified when the alarm was set with <a href="#">AlmSetAlarm</a> .
	-> alarmSeconds	The date/time specified when the alarm was set with <code>AlmSetAlarm</code> . The value is given as the number of seconds since 1/1/1904.
	<- purgeAlarm	Upon return, set to <code>true</code> if the alarm should be removed from the alarm table. Use this as an optimization to prevent the application from receiving <a href="#">sysAppLaunchCmdDisplayAlarm</a> if you don't wish to perform any other processing for this alarm. If you do want to receive the launch code, set this field to <code>false</code> .

## Application Launch Codes

### Launch Codes

---

padding      Not used.

## sysAppLaunchCmdAttention

Perform the action requested by the attention manager. This launch code is accompanied by a value of the `AttnCommand` type; this type specifies the set of possible commands that can be sent to the application that requested the alarm.

```
typedef UInt16 AttnCommand;
```

The following table lists the values that `AttnCommand` can assume.

**Table 1.2 sysAppLaunchCmdAttention Commands**

Constant	Value	Description
<code>AttnCommand_drawDetail</code>	<code>((AttnCommand) 1)</code>	Indicates that the application needs to draw the detailed contents of the attention dialog. The command arguments parameter points to a structure of type <a href="#">AttnCommandDrawDetailArgsType</a> .
<code>AttnCommand_drawList</code>	<code>((AttnCommand) 2)</code>	Indicates that the application needs to draw the appropriate list item in the attention dialog. The command arguments parameter points to a structure of type <a href="#">AttnCommandDrawListArgsType</a> .

**Table 1.2 sysAppLaunchCmdAttention Commands**

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>AttnCommand_customEffect</code>	<code>((AttnCommand) 3)</code>	Indicates that the Attention Manager is doing something to get the user's attention, and any application-specific special effect should be done. This command is only sent to attention items that set the <code>AttnFlags_CustomEffectBit</code> when they call <a href="#">AttnGetAttention</a> , which most applications won't do.
<code>AttnCommand_goThere</code>	<code>((AttnCommand) 4)</code>	Tells the application to navigate to the item. The command arguments parameter is NULL. An application commonly calls <a href="#">SysAppLaunch</a> upon receipt of this command to have itself launched.
<code>AttnCommand_gotIt</code>	<code>((AttnCommand) 5)</code>	Tells the application that the user is dismissing the item. The command arguments parameter is NULL. The application may choose to clean up memory at this point.

## Application Launch Codes

### Launch Codes

---

**Table 1.2 sysAppLaunchCmdAttention Commands**

Constant	Value	Description
AttnCommand_snooze	((AttnCommand) 6)	Indicates to the application that the user is snoozing. The command arguments parameter is NULL. Most applications do nothing upon receipt of this command. This command is passed to each and every item currently pending, insistent or subtle. Applications with more than one attention item pending are called more than once.
AttnCommand_iterate	((AttnCommand) 7)	This command is passed to the application during the enumeration of attention items. This command is particularly useful after HotSync operations, as it allows the application to examine each item, updating or removing those that are stale or invalid.

---

### AttnCommandDrawDetailArgsType

When `AttnCommand_drawDetail` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, the application needs to draw the detailed contents of the attention dialog. The `AttnCommandDrawDetailArgsType` structure accompanies the `AttnCommand_drawDetail` command, and provides the information needed to draw the contents of that dialog.

```
typedef struct {
    RectangleType bounds;
    Boolean firstTime;
    AttnFlagsType flags;
} AttnCommandDrawDetailArgsType;
```

### Field Descriptions

<code>bounds</code>	Contains the window-relative bounding box for the area to draw. The clipping region is also set to the dimensions of this box to prevent accidental drawing outside.
<code>firstTime</code>	Set to <code>true</code> if the user has not yet seen this item. The value of this field could be used, for example, to display attentions that the user hasn't seen before in some special way.
<code>flags</code>	The global user preferences for this attention attempt combined with the custom flags passed in by the developer. For example, if the global preference is to mute sounds, and the developer flags are both zero, then the <code>AttnFlags_NoSound</code> flag is on and the <code>AttnFlags_AlwaysSound</code> flag is off.

### AttnCommandDrawListArgsType

When `AttnCommand_drawList` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, the application is to draw the appropriate list item in the attention dialog. The `AttnCommandDrawListArgsType` structure accompanies the `AttnCommand_drawList` command, and provides the information needed to draw the contents of that dialog.

```
typedef struct {
    RectangleType bounds;
    Boolean firstTime;
    AttnFlagsType flags;
}
```

## Application Launch Codes

### Launch Codes

---

```
} AttnCommandDrawListArgsType;
```

#### Field Descriptions

<code>bounds</code>	Contains the window-relative bounding box for the area to draw. The clipping region is also set to the dimensions of this box to prevent accidental drawing outside.
<code>firstTime</code>	Set to <code>true</code> if the user has not yet seen this item. The value of this field could be used, for example, to trigger a custom sound the first time this attention item is presented to the user.
<code>flags</code>	The global user preferences for this attention attempt combined with the custom flags passed in by the developer. For example, if the global preference is to mute sounds, and the developer flags were both zero, then the <code>AttnFlags_NoSound</code> flag is on and the <code>AttnFlags_AlwaysSound</code> flag is off.

#### AttnCommandGotItArgsType

When `AttnCommand_getIt` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, it is accompanied by an `AttnCommandGotItArgsType` structure. This structure indicates whether the `AttnCommand_getIt` command was generated because the user dismissed the attention, or whether the system is simply informing your application that [AttnForgetIt](#) was called. Your application normally ignores the latter case if your application made the call to `AttnForgetIt`.

```
typedef struct {
    Boolean dismissedByUser;
} AttnCommandGotItArgsType;
```

## Field Descriptions

<code>dismissedByUser</code>	<code>true</code> indicates that the user dismissed the attention. <code>false</code> indicates that the <code>AttnCommandGotIt</code> command was generated by a call to <code>AttnForgetIt</code> .
------------------------------	---

## sysAppLaunchCmdCardLaunch

This launch code is sent to applications that are being run from an expansion card. The application is copied into the device's main memory prior to being sent this launch code. If the application doesn't respond to `sysAppLaunchCmdCardLaunch`, it is then sent a `sysAppLaunchNormalLaunch` launch code. Applications that can profit from the knowledge that they are being launched from an expansion card may want to consult the fields in the parameter block that accompanies `sysAppLaunchCmdCardLaunch`.

When the Launcher sends `sysAppLaunchCmdCardLaunch` to an application, it also sends [sysAppLaunchFlagNewGlobals](#), and [sysAppLaunchFlagUIApp](#) flags. These two flags are not sent to `start.prc`, however. Applications should never interact with the user upon receiving this launch code, and should not depend on globals being available. This launch code is intended to notify the application that it is being launched from a card. Applications typically save some state information upon receiving this launch code and do the bulk of their processing when they receive `sysAppLaunchNormalLaunch`.

## sysAppLaunchCmdCardLaunch Parameter Block

<b>Prototype</b>	<pre>typedef struct {     Err    err;     UInt16 volRefNum;     const Char *path;     UInt16 startFlags;</pre>
------------------	--

## Application Launch Codes

### Launch Codes

---

```
} SysAppLaunchCmdCardType;
```

<b>Fields</b>	<code>&lt;- err</code>	Initially set to <code>expErrUnsupportedOperation</code> , applications that recognize <code>sysAppLaunchCmdCardLaunch</code> and that don't want to receive the subsequent <code>sysAppLaunchNormalLaunch</code> launch code should set this field to <code>errNone</code> .
	<code>-&gt; volRefNum</code>	The reference number of the volume from which the application is being launched.
	<code>-&gt; path</code>	The complete path to the application being launched.
	<code>&lt;-&gt; startFlags</code>	This field is made up of a combination of the following flags.  <code>sysAppLaunchStartFlagAutoStart</code> Indicates that the application is being run automatically upon card insertion.  <code>sysAppLaunchStartFlagNoUISwitch</code> Set this bit to prevent a UI switch to the application.  <code>sysAppLaunchStartFlagNoAutoDelete</code> Set this bit to prevent the VFS Manager from deleting the copy of the application in main memory when the associated volume is unmounted.

### **sysAppLaunchCmdCountryChange**

Responds to country change.

Applications should change the display of numbers to use the proper number separators. To do this, call [LocGetNumberSeparators](#), `StrLocalizeNumber`, and `StrDelocalizeNumber`.

### **sysAppLaunchCmdDisplayAlarm**

Performs full, possibly blocking, handling of alarm.

This is the application's opportunity to handle an alarm in a lengthy or blocking fashion. Alert dialogs are usually displayed when this launch code is received. This work should be done here, not when [sysAppLaunchCmdAlarmTriggered](#) is received. Multiple alarms may be pending at the same time for multiple applications, and one alarm display shouldn't block the system and prevent other applications from receiving their alarms in a timely fashion.

### sysAppLaunchCmdDisplayAlarm Parameter Block

**Prototype**

```
typedef struct SysDisplayAlarmParamType {
    UInt32      ref;
    UInt32      alarmSeconds;
    Boolean      soundAlarm;
    UInt8       padding;
} SysDisplayAlarmParamType;
```

**Fields**

- > `ref`            The caller-defined value specified when the alarm was set with [AlmSetAlarm](#).
- > `alarmSeconds`    The date/time specified when the alarm was set with `AlmSetAlarm`. The value is given as the number of seconds since 1/1/1904.
- > `soundAlarm`    `true` if the alarm should be sounded, `false` otherwise. This value is currently not used.
- `padding`        Not used.

### sysAppLaunchCmdExgAskUser

The Exchange Manager sends the `sysAppLaunchCmdExgAskUser` launch code to the application when data has arrived for that application. This launch code allows the application to tell the Exchange Manager not to display the exchange dialog, which it uses to have the user confirm the receipt of data. If the application does not handle this launch code, the default course of action is that the Exchange Manager displays the exchange dialog.

Applications may want to respond to this launch code under these circumstances:

## Application Launch Codes

### Launch Codes

---

- To reject all incoming data or to reject data under certain circumstances without first prompting the user. To reject incoming data, set the `result` field of the parameter block to `exgAskCancel` and then return.
- To receive incoming data without confirmation. To automatically receive incoming data, set the result field to `exgAskOk`.
- To provide a user confirmation dialog with extra functionality. This is described in more detail below.

Starting with Palm OS 3.5, the Exchange Manager allows applications to provide extra functionality in the exchange dialog. You can have the dialog include a category pop-up list from which the user chooses a category in which to file the incoming data. If you want to provide a category pop-up list, call the [ExgDoDialog](#) function in response to this launch code and pass it a database that contains the categories to be listed. See the description of that function for more information.

Applications may also bypass the call to `ExgDoDialog` altogether and provide their own dialogs.

If an application responds to this launch code, it must set the `result` field in the parameter block to the appropriate value. Possible values are:

<code>exgAskDialog</code>	Display the default exchange dialog provided by Exchange Manager.
<code>exgAskOk</code>	Accept the incoming data.
<code>exgAskCancel</code>	Reject the incoming data.

On Palm OS 3.5 or higher if you don't use the default version of the dialog, return `exgAskOk` if the user confirmed or `exgAskCancel` if the user canceled. If you don't set the `result` field properly, two dialogs are displayed.

---

**IMPORTANT:** Implemented only if [3.0 New Feature Set](#) is present.

---

**sysAppLaunchCmdExgAskUser Parameter Block**

**Prototype**

```
typedef struct {
    ExgSocketPtr      socketP;
    ExgAskResultType result;
    UInt8             reserved;
} ExgAskParamType;
```

**Fields**

<-> socketP	Socket pointer (see <a href="#">ExgSocketType</a> )
<- result	Show dialog, auto-confirm, or auto-cancel
-> reserved	Reserved for future use

**sysAppLaunchCmdExgGetData**

The Exchange Manager sends the `sysAppLaunchCmdExgGetData` launch code when the exchange library requests data to be sent to a remote device. That is, an application on a remote device has performed an [ExgGet](#) function to request data, and the Exchange Manager has determined that the launched application should handle the request.

To respond to this launch code, applications should initiate a connection with [ExgPut](#), use [ExgSend](#) to send the data, and call [ExgDisconnect](#) when finished.

The parameter block sent with this launch code is a pointer to the [ExgSocketType](#) structure corresponding to the Exchange Manager connection on which the data is to be sent. You pass this socket pointer to `ExgPut`. For more details, see the “[Exchange Manager](#)” chapter.

---

**IMPORTANT:** Implemented only if [4.0 New Feature Set](#) is present.

---

**sysAppLaunchCmdExgPreview**

Following the launch code [sysAppLaunchCmdExgAskUser](#), the Exchange Manager sends the `sysAppLaunchCmdExgPreview` launch code to have the application display the preview in the exchange dialog.

## Application Launch Codes

### Launch Codes

---

#### sysAppLaunchCmdExgPreview Parameter Block

**Prototype**

```
typedef struct {
    UInt16          version;
    ExgSocketType  *socketP;
    UInt16          op;
    Char           *string;
    UInt32          size;
    RectangleType  bounds;
    UInt16          types;
    Err            error;
} ExgPreviewInfoType;
```

**Fields**

- > version      Set this field to 0 to specify version 0 of this structure.
  
- > socketP      A pointer to the socket structure (see [ExgSocketType](#)). The libraryRef field must point to the exchange library from which preview data should be received.
  
- > op            A constant that identifies the operation. This can be one of the following:
  - exgPreviewDialog  
    Display a form or modal dialog containing the preview. This constant is only used in situations where one application launches another to display data.
  
  - exgPreviewDraw  
    Draw the preview as a graphic in the bounds rectangle.
  
  - exgPreviewLongString  
    Return the preview as a long string in the string field.
  
  - exgPreviewQuery  
    Return the list of preview modes the application supports in the types field.
  
  - exgPreviewLongString  
    Return the preview as a short string in the string field.

<code>&lt;- string</code>	A buffer into which the preview string is placed if one of the string preview operations is specified.
<code>-&gt; size</code>	The allocated size of the <code>string</code> field.
<code>-&gt; bounds</code>	The bounds of the rectangle in which to draw the graphic if the preview operation is <code>exgPreviewDraw</code> .
<code>&lt;- types</code>	Upon return from <code>exgPreviewQuery</code> , a bit field identifying the types of previews the library supports ( <code>exgPreviewDraw</code> , <code>exgPreviewLongString</code> , or <code>exgPreviewShortString</code> ).
<code>&lt;- error</code>	The error code returned from the library. If this is <code>errNone</code> , the preview operation was successful.

Applications that respond to this launch code should check the parameter block's `op` field and respond as described above.

Applications can define and use their own constants for the preview operation. Operations specific to an application are numbered starting at `exgPreviewFirstUser` and should be no greater than `exgPreviewLastUser`.

Applications respond to this launch in much the same way they respond to [sysAppLaunchCmdExgReceiveData](#). Use [ExgAccept](#) to accept the preview connection, [ExgReceive](#) to receive the data, and then [ExgDisconnect](#) to end the connection. The only difference is what is done with the data when it is received. With this launch code, the application should return the data in the `string` field or draw it in the `bounds` rectangle. With the `sysAppLaunchCmdExgReceiveData` launch code, the application stores the received data.

---

**IMPORTANT:** Implemented only if [4.0 New Feature Set](#) is present.

---

## Application Launch Codes

### Launch Codes

---

### sysAppLaunchCmdExgReceiveData

The Exchange Manager sends the `sysAppLaunchCmdExgReceiveData` launch code following the [sysAppLaunchCmdExgAskUser](#) and [sysAppLaunchCmdExgPreview](#) launch codes to notify the application that it should receive the data (assuming that the application and/or the user has indicated the data should be received).

The application should use Exchange Manager functions to receive the data and store it or do whatever it needs to with the data. Specifically, most applications should respond to this launch code by calling [ExgAccept](#) to accept the connection and then [ExgReceive](#) to receive the data.

Note that the application may not be the active application, and thus may not have globals available when it is launched with this launch code. You can check if you have globals by using this code in the [PilotMain](#) routine:

---

```
Boolean appIsActive = launchFlags & sysAppLaunchFlagSubCall;
```

---

The `appIsActive` value is `true` if your application is active and globals are available; otherwise, you won't be able to access any of your global variables during the receive operation.

The parameter block sent with this launch code is a pointer to the [ExgSocketType](#) structure corresponding to the Exchange Manager connection on which the data is arriving. Pass this pointer to the [ExgAccept](#) function to begin receiving the data. For more details, refer to the "[Exchange Manager](#)" chapter.

---

**IMPORTANT:** Implemented only if [3.0 New Feature Set](#) is present.

---

### sysAppLaunchCmdFind

This launch code is used to implement the global find. When the user enters a text string in the Find dialog, the system sends this launch code with the `FindParamsType` parameter block to each

application. The application should search for the string that the user entered and return any records matching the find request.

The system displays the results of the query in the Find results dialog. The system continues the search with each application until it has a full screen of matching records or until all of the applications on the device have had a chance to respond. If the screen is full, a Find More button appears at the bottom of the dialog. If the user clicks the Find More button, the search resumes. Applications can test whether the current find is a continuation of a previous one by checking the `continuation` field in the parameter block.

Most applications that use text records should support this launch code. When they receive it, they should search all records for matches to the find string and return all matches. Functions that you can use to respond to this launch code are described in [Chapter 10, "Find."](#)

An application can also integrate the find operation in its own user interface and send the launch code to a particular application.

Applications that support this launch code should support [sysAppLaunchCmdSaveData](#) and [sysAppLaunchCmdGoto](#) as well.

### sysAppLaunchCmdFind Parameter Block

**Prototype**

```
typedef struct {
    UInt16      dbAccessMode;
    UInt16      recordNum;
    Boolean     more;
    Char        strAsTyped [maxFindStrLen+1];
    Char        strToFind [maxFindStrLen+1];
    UInt8       reserved1;
    UInt16      numMatches;
    UInt16      lineNumber;
    Boolean     continuation;
    Boolean     searchedCaller;
    LocalID     callerAppDbID;
    UInt16      callerAppCardNo;
    LocalID     appDbID;
    UInt16      appCardNo;
    Boolean     newSearch;
    UInt8       reserved2;
    DmSearchStateType searchState;
}
```

## Application Launch Codes

### Launch Codes

---

```
        FindMatchType          match [maxFinds];  
    } FindParamsType;
```

<b>Fields</b>	<code>dbAccessMode</code>	Mode in which to open the application's database. Pass this directly to <a href="#">DmOpenDatabase</a> as the mode parameter. Its value is either <code>dmModeReadOnly</code> or <code>dmModeReadOnly   dmModeShowSecret</code> . (See " <a href="#">Open Mode Constants</a> " for more information.)
	<code>recordNum</code>	Index of last record that contained a match. Start the search from this location. Do not set this value directly. Instead, call <a href="#">FindSaveMatch</a> when you have a matching record.
	<code>more</code>	If <code>true</code> , the Find results dialog displays the Find More button indicating that there may be more results to display.  Typically <a href="#">FindSaveMatch</a> handles setting the <code>more</code> field. Applications with large databases to search may want to periodically check for and stop the search if an event is pending. If so, they should set this field to <code>true</code> before stopping.
	<code>strAsTyped</code>	Search string as the user entered it.
	<code>strToFind</code>	Normalized version of the search string. The method by which a search string is normalized varies depending on the version of Palm OS and the character encoding supported by the device. You pass <code>strToFind</code> directly to the search function (either <a href="#">FindStrInStr</a> , <a href="#">TxtFindString</a> , or <a href="#">TxtGlueFindString</a> ).
	<code>reserved1</code>	Reserved for future use.
	<code>numMatches</code>	The current number of matches. Do not set this field directly. Instead, call <a href="#">FindSaveMatch</a> , which increments it for you.

<code>lineNumber</code>	Line number of the next line that displays the results. Do not set this field directly. It is incremented by a call to <a href="#">FindDrawHeader</a> .
<code>continuation</code>	If <code>true</code> , the launch code is being sent as part of a continuation of a previous Find. If <code>false</code> , this is a new Find. Do not set this field directly; the system sets it when the Find results dialog is full.
<code>searchedCaller</code>	If <code>true</code> , the application that was active at the time the user tapped the Find button has responded to this launch code. This application is always searched before any others.
<code>callerAppDbID</code>	Database ID of the application that was active when the user tapped the Find button. Do not change the value of this field; the system sets it and uses it when searching for application databases.
<code>callerAppCardNo</code>	Card number of the application that was active when the user tapped the Find button. Do not change the value of this field; the system sets it and uses it when searching for application databases.
<code>appDbID</code>	The ID of your application's resource database. Do not set this field directly; the system sets it and uses it when searching for application databases.
<code>appCardNo</code>	The card number of your application's resource database. Do not set this field directly; the system sets it and uses it when searching for application databases.
<code>newSearch</code>	System use only.
<code>reserved2</code>	Reserved for future use.
<code>searchState</code>	System use only.
<code>match</code>	System use only.

## Application Launch Codes

### Launch Codes

---

## sysAppLaunchCmdGoto

Sent in conjunction with [sysAppLaunchCmdFind](#) or [sysAppLaunchCmdExgReceiveData](#) to allow users to actually inspect the record that the global find returned or that was received by the Exchange Manager.

Applications should do most of the normal launch actions, then display the requested item. The application should continue running unless explicitly closed.

An application launched with this code does have access to global variables, static local variables, and code segments other than segment 0 (in multi-segment applications).

Applications that receive this launch code should test the `sysAppLaunchFlagNewGlobals` launch flag to see if they need to initialize global variables. `sysAppLaunchFlagNewGlobals` indicates that the system has just allocated your global variables.

For example:

```
case sysAppLaunchCmdGoTo:
    if (launchFlags & sysAppLaunchFlagNewGlobals)
        StartApplication();
```

Note that you shouldn't automatically initialize the global variables in response to this launch code. Test the launch flag first. Your application receives this launch code when the user selects a record in the global find results. If your application was the current application before the user selected the Find command, the launch flag is clear to indicate that your globals should not be re-initialized.

## sysAppLaunchCmdGoto Parameter Block

**Prototype**

```
typedef struct {
    Int16      searchStrLen;
    UInt16     dbCardNo;
    LocalID    dbID;
    UInt16     recordNum;
    UInt16     matchPos;
    UInt16     matchFieldNum;
    UInt32     matchCustom;
} GoToParamsType;
```

<b>Fields</b>	<code>searchStrLen</code>	Length of normalized search string. This is <b>not</b> the length of the matching string. See below for a full explanation.
	<code>dbCardNo</code>	Card number of the database to open.
	<code>dbID</code>	Local ID of the database to open.
	<code>recordNum</code>	Index of record containing a match.
	<code>matchPos</code>	Position of the match within the field.
	<code>matchFieldNum</code>	Field number string was found in.
	<code>matchCustom</code>	Application-specific information.

Often, applications highlight the search string when displaying the resulting record. Localizable applications commonly store the length of the string to select in the `matchCustom` field for this purpose. Some multi-byte character encodings represent certain characters both as a single-byte character and a multi-byte character. When the search is performed, the single-byte character is accurately matched against its multi-byte equivalent. For this reason, the length of the string searched for does not always equal the length of the matching string. Applications that support being localized to multi-byte character sets often set the `matchCustom` field to the length of the matching string in the call to [FindSaveMatch](#) so that they know the length of the string to select.

### sysAppLaunchCmdGoToURL

Applications can respond to this launch code to retrieve and display the specified URL.

The parameter block for this launch command is simply a pointer to a string containing the URL.

This launch code may be sent in the following instances:

- If the [Wireless Internet Feature Set](#) is, applications can send this launch code directly to the Web Clipping Application Viewer application.
- If [4.0 New Feature Set](#) is present, the [ExgRequest](#) function launches an application with this launch code if it cannot find an exchange library that is registered for the URL it has

## Application Launch Codes

### Launch Codes

---

received. To receive the launch code, the application must first use [ExgRegisterDatatype](#) to register for a URL scheme.

---

**IMPORTANT:** Implemented only if [Wireless Internet Feature Set](#) is present.

---

### **sysAppLaunchCmdHandleSyncCallApp**

This launch command is sent by the Desktop Link server when `SyncCallRemoteModule` is called from a conduit to request that the handheld application do some processing on the conduit's behalf.

Along with this launch code you receive a `sysAppLaunchCmdHandleSyncCallApp` parameter block which contains all of the information passed to `SyncCallRemoteModule` on the desktop plus the fields needed to pass the result back to the desktop. Pass the results back to the conduit by calling [DlkControl](#). See the comments section for `DlkControl` in the *Palm OS Programmer's API Reference* for an example of how to handle this launch code.

**sysAppLaunchCmdHandleSyncCallApp Parameter Block**

**Prototype**

```
typedef struct
SysAppLaunchCmdHandleSyncCallAppType {
    UInt16 pbSize;
    UInt16 action;
    void *paramP;
    UInt32 dwParamSize;
    void *dlRefP;
    Boolean handled;
    UInt8 reserved1;
    Err replyErr;
    UInt32 dwReserved1;
    UInt32 dwReserved2;
} SysAppLaunchCmdHandleSyncCallAppType;
```

<b>Fields</b>	pbSize	Size, in bytes, of this parameter block. Set to sizeof (SysAppLaunchCmdHandleSyncCallAppType).
	action	Call action ID (application-specific).
	paramP	Pointer to parameter block (call action ID specific).
	dwParamSize	Parameter block size, in bytes.
	dlRefP	DesktopLink reference pointer. Supply this value in the <a href="#">DlkCallAppReplyParamType</a> structure when calling <a href="#">DlkControl</a> with the dlkCtlSendCallAppReply control code.
	handled	Initialized to false by DLServer; if handled, your application must set it to true (and your handler the handler must call <a href="#">DlkControl</a> with the dlkCtlSendCallAppReply control code). If your handler is not going to send a reply back to the conduit, leave this field set to false, in which case the DesktopLink Server will send the default "unknown request" reply.
	reserved1	Reserved. Set to NULL.

## Application Launch Codes

### Launch Codes

---

replyErr	Error code returned from the call to <a href="#">DlkControl</a> with the <code>dlkCtlSendCallAppReply</code> control code.
dwReserved1	Reserved. Set to NULL.
dwReserved2	Reserved. Set to NULL.

### sysAppLaunchCmdInitDatabase

This launch code is sent by the Desktop Link server in response to a request to create a database. It is sent to the application whose creator ID matches that of the requested database.

The most frequent occurrence of this is when a 'data' database is being installed or restored from the desktop. In this case, HotSync creates a new database on the device and passes it to the application via a `sysAppLaunchCmdInitDatabase` command, so that the application can perform any required initialization. HotSync will then transfer the records from the desktop database to the device database.

When a Palm OS application crashes while a database is installed using HotSync, the reason may be that the application is not handling the `sysAppLaunchCmdInitDatabase` command properly. Be especially careful not to access global variables.

The system will create a database and pass it to the application for initialization. The application must perform any initialization required, then pass the database back to the system, unclosed.

### sysAppLaunchCmdInitDatabase Parameter Block

**Prototype**

```
typedef struct {
    DmOpenRef    dbP;
    UInt32       creator;
    UInt32       type;
    UInt16       version;
} SysAppLaunchCmdInitDatabaseType;
```

<b>Fields</b>	dbP	Database reference.
	creator	Database creator.
	type	Database type.

`version` Database version.

### **sysAppLaunchCmdLookup**

The system or an application sends this launch command to retrieve information from another application. In contrast to `Find`, there is a level of indirection; for example, this launch code could be used to retrieve the phone number based on input of a name.

This functionality is currently supported by the standard Palm OS Address Book.

Applications that decide to handle this launch code must search their database for the string the user entered and perform the match operation specified in the launch code's parameter block.

If an application wants to allow its users to perform lookup in other applications, it has to send it properly, including all information necessary to perform the match. An example for this is in `Address.c` and `AppLaunchCmd.h`, which are included in your SDK.

#### **sysAppLaunchCmdLookup Parameter Block**

The parameter block is defined by the application that supports this launch code. See `AppLaunchCmd.h` for an example.

---

**IMPORTANT:** Implemented only if [2.0 New Feature Set](#) is present.

---

### **sysAppLaunchCmdNotify**

The system or an application sends this launch code to notify applications that an event has occurred. The parameter block specifies the type of event that occurred, as well as other pertinent information. To learn which notifications are broadcast by the system, see the chapter titled "[Notifications](#)" in this book.

---

**IMPORTANT:** Implemented only if [Notification Feature Set](#) is present.

---

## Application Launch Codes

### Launch Codes

---

#### sysAppLaunchCmdNotify Parameter Block

The [SysNotifyParamType](#) structure declared in `NotifyMgr.h` defines the format of this launch code's parameter block. See its description in the "Notifications" chapter.

#### sysAppLaunchCmdOpenDB

You can send this launch code to the Web Clipping Application Viewer application to launch the application and cause it to open and display a Palm™ query application stored on the device. This is the same mechanism that the Launcher uses to launch query applications.

---

**IMPORTANT:** Implemented only if [Wireless Internet Feature Set](#) is present.

---

#### sysAppLaunchCmdOpenDB Parameter Block

**Prototype**

```
typedef struct {
    UInt16      cardNo;
    LocalID     dbID;
} SysAppLaunchCmdOpenDBType;
```

**Fields**

<code>cardNo</code>	Card number of database to open.
<code>dbID</code>	Database id of database to open.

#### sysAppLaunchCmdPanelCalledFromApp

`sysAppLaunchCmdPanelCalledFromApp` and [sysAppLaunchCmdReturnFromPanel](#) allow an application to let users change preferences without switching to the Preferences application. For example, for the calculator, you may launch the Formats preferences panel, set up a number format preference, then directly return to the calculator that then uses the new format.

`sysAppLaunchCmdPanelCalledFromApp` lets a preferences panel know whether it was switched to from the Preferences application or whether an application invoked it to make a change. The panel may be a preference panel owned by the application or a system preferences panel.

Examples of these system panels that may handle this launch code are:

- Network panel (called from network applications)
- Modem panel (called if modem selection is necessary)

All preferences panels must handle this launch code. If a panel is launched with this command, it should:

- Display a Done button.
- **Not** display the panel-switching pop-up trigger used for navigation within the preferences application.

---

**IMPORTANT:** Implemented only if [2.0 New Feature Set](#) is present.

---

### **sysAppLaunchCmdReturnFromPanel**

This launch code is used in conjunction with [sysAppLaunchCmdPanelCalledFromApp](#). It informs an application that the user is done with a called preferences panel. The system passes this launch code to the application when a previously-called preferences panel exists.

---

**IMPORTANT:** Implemented only if [2.0 New Feature Set](#) is present.

---

### **sysAppLaunchCmdSaveData**

Instructs the application to save all current data. For example, before the system performs a global find, an application should save all data.

Any application that supports the Find command and that can have buffered data should support this launch code. The system sends this launch code to the currently active application before it begins the search. The application receiving this launch code should respond by saving all buffered data so that the search is able to find matches in the text just entered.

## Application Launch Codes

### Launch Codes

---

#### sysAppLaunchCmdSaveData Parameter Block

**Prototype**

```
typedef struct {
    Boolean    uiComing;
    UInt8     reserved1;
} SysAppLaunchCmdSaveDataType;
```

**Fields**

uiComing	true if the system dialog is displayed before launch code arrives.
reserved1	Reserved for future use.

#### sysAppLaunchCmdSyncNotify

This launch code is sent to applications to inform them that a HotSync operation has occurred.

This launch code is sent only to applications whose databases were changed during the HotSync operation. (Installing the application database itself is considered a change.) The record database(s) must have the same creator ID as the application in order for the system to know which application to send the launch code to.

This launch code provides a good opportunity to update, initialize, or validate the application's new data, such as resorting records, setting alarms, and so on.

Because applications only receive `sysAppLaunchCmdSyncNotify` when their databases are updated, this launch code is not a good place to perform any operation that must occur after every HotSync operation. Instead, you may register to receive the `sysNotifySyncFinishEvent` on systems that have the [Notification Feature Set](#). This notification is sent at the end of a HotSync operation, and it is sent to all applications registered to receive it, whether the application's data changed or not. Note that there is also a `sysNotifySyncStartEvent` notification.

#### sysAppLaunchCmdSystemLock

Launch code sent to the system-internal security application to lock the device.

As a rule, applications don't need to do respond to this launch code. If an application replaces the system-internal security application, it must handle this launch code.

---

**IMPORTANT:** Implemented only if [2.0 New Feature Set](#) is present.

---

## sysAppLaunchCmdSystemReset

Launch code to respond to system soft or hard reset.

Applications can respond to this launch code by performing initialization, indexing, or other setup that they need to do when the system is reset. For more information about resetting the device, see "[System Boot and Reset](#)" in the *Palm OS Programmer's Companion*, vol. I.

### sysAppLaunchCmdSystemReset Parameter Block

#### Prototype

```
typedef struct {
    Boolean    hardReset;
    Boolean    createDefaultDB;
} SysAppLaunchCmdSystemResetType;
```

#### Fields

<code>hardReset</code>	true if system was hardReset. false if system was softReset.
<code>createDefaultDB</code>	If true, application has to create default database.

## sysAppLaunchCmdTimeChange

Launch code to respond to a time change initiated by the user.

Applications that are dependent on the current time or date need to respond to this launch code. For example, an application that sets alarms may want to cancel an alarm or set a different one if the system time changes.

On systems that have the [Notification Feature Set](#), applications should register to receive the `sysNotifyTimeChangeEvent`

## Application Launch Codes

### Launch Flags

---

notification instead of responding to this launch code. The `sysAppLaunchCmdTimeChange` launch code is sent to all applications. The `sysNotifyTimeChangeEvent` notification is sent only to applications that have specifically registered to receive it, making it more efficient than `sysAppLaunchCmdTimeChange`.

### **sysAppLaunchCmdURLParams**

This launch code is sent from the Web Clipping Application Viewer application to launch another application.

The parameter block consists of a pointer to a special URL string, which the application must know how to parse. The string is the URL used to launch the application and may contain encoded parameters.

An application launched with this code may or may not have access to global variables, static local variables, and code segments other than segment 0 (in multi-segment applications). It depends on the URL that caused the Web Clipping Application Viewer to send this launch code. If this launch code results from a `palm` URL, then globals are available. If the launch code results from a `palmcall` URL, then globals are not available.

The best way to test if you have global variable access is to test the `sysAppLaunchFlagNewGlobals` launch flag sent with this launch code. If this flag is set, then you have global variable access.

---

**IMPORTANT:** Implemented only if [Wireless Internet Feature Set](#) is present.

---

## Launch Flags

When an application is launched with any launch command, it also is passed a set of launch flags.

An application may decide to ignore the flags even if it handles the launch code itself. For applications that decide to use the launch flags, the following table provides additional information:

**Table 1.3 Launch Flags**

<b>Flag</b>	<b>Functionality</b>
<code>sysAppLaunchFlagNewGlobals</code>	Set when the system has created and initialized a new globals world for the application. Implies new owner ID for memory chunks.
<code>sysAppLaunchFlagUIApp</code>	Set when a UI application is being launched.
<code>sysAppLaunchFlagSubCall</code>	Set when the application is calling its entry point as a subroutine call. This tells the launch code that it's OK to keep the A5 (globals) pointer valid through the call. If this flag is set, it indicates that the application is already running as the current application.

---

---

**IMPORTANT:** Applications should never set launch flags when sending a launch code to another application. They should only be set by the system. In particular, note that you should never pass `sysAppLaunchFlagNewGlobals` as a launch flag for `SysAppLaunch`. If you do and you make repeated calls to `SysAppLaunch`, the system eventually runs out of owner IDs, and the new application fails to launch.

---

## **Application Launch Codes**

### *Launch Flags*

---

# Palm OS Events

---

Palm OS® events are structures (defined in the header files `Event.h`, `SysEvent.h`, and `INetMgr.h`) that the system passes to the application when the user interacts with the graphical user interface. [Chapter 3, “Event Loop,”](#) on page 53, in the *Palm OS Programmer’s Companion*, vol. I discusses in detail how this works. This chapter provides reference-style information about each event. First it shows the types used by Palm OS events. Then it discusses the following events in alphabetical order:

Event	UI Object
<a href="#">appStopEvent</a>	N.A.
<a href="#">ctlEnterEvent</a> , <a href="#">ctlExitEvent</a> , <a href="#">ctlRepeatEvent</a> , <a href="#">ctlSelectEvent</a>	Control
<a href="#">daySelectEvent</a>	N.A.
<a href="#">fldChangedEvent</a> , <a href="#">fldEnterEvent</a> , <a href="#">fldHeightChangedEvent</a>	Field
<a href="#">frmCloseEvent</a> , <a href="#">frmGotoEvent</a> , <a href="#">frmLoadEvent</a> , <a href="#">frmOpenEvent</a> , <a href="#">frmSaveEvent</a> , <a href="#">frmUpdateEvent</a> , <a href="#">frmTitleEnterEvent</a> , <a href="#">frmTitleSelectEvent</a>	Form
<a href="#">frmGadgetEnterEvent</a> , <a href="#">frmGadgetMiscEvent</a>	Extended gadget
<a href="#">inetSockReadyEvent</a> , <a href="#">inetSockStatusChangeEvent</a>	N.A. (INetLib)
<a href="#">keyDownEvent</a>	N.A.
<a href="#">lstEnterEvent</a> , <a href="#">lstExitEvent</a> , <a href="#">lstSelectEvent</a>	List
<a href="#">menuEvent</a> , <a href="#">menuOpenEvent</a> , <a href="#">menuCloseEvent</a> , <a href="#">menuCmdBarOpenEvent</a>	Menu
<a href="#">nilEvent</a>	N.A.
<a href="#">penDownEvent</a> , <a href="#">penMoveEvent</a> , <a href="#">penUpEvent</a>	N.A. (pen)

## Palm OS Events

### Event Data Structures

---

Event	UI Object
<a href="#">popSelectEvent</a>	Popup (Control)
<a href="#">sclEnterEvent</a> , <a href="#">sclRepeatEvent</a> , <a href="#">sclExitEvent</a>	Scroll bar
<a href="#">tblEnterEvent</a> , <a href="#">tblExitEvent</a> , <a href="#">tblSelectEvent</a>	Table
<a href="#">winEnterEvent</a> , <a href="#">winExitEvent</a>	Window

---

## Event Data Structures

### eventsEnum

The `eventsEnum` enum specifies the possible event types.

```
enum events {
    nilEvent = 0,
    penDownEvent,
    penUpEvent,
    penMoveEvent,
    keyDownEvent,
    winEnterEvent,
    winExitEvent,
    ctlEnterEvent,
    ctlExitEvent,
    ctlSelectEvent,
    ctlRepeatEvent,
    lstEnterEvent,
    lstSelectEvent,
    lstExitEvent,
    popSelectEvent,
    fldEnterEvent,
    fldHeightChangedEvent,
    fldChangedEvent,
    tblEnterEvent,
    tblSelectEvent,
    daySelectEvent,
    menuEvent,
    appStopEvent = 22,
    frmLoadEvent,
```

```
    frmOpenEvent ,
    frmGotoEvent ,
    frmUpdateEvent ,
    frmSaveEvent ,
    frmCloseEvent ,
    frmTitleEnterEvent ,
    frmTitleSelectEvent ,
    tblExitEvent ,
    sclEnterEvent ,
    sclExitEvent ,
    sclRepeatEvent ,
    tsmFepModeEvent ,

    menuCmdBarOpenEvent = 0x0800 ,
    menuOpenEvent ,
    menuCloseEvent ,
    frmGadgetEnterEvent ,
    frmGadgetMiscEvent ,

    firstINetLibEvent = 0x1000 ,
    firstWebLibEvent = 0x1100 ,

    firstUserEvent = 0x6000 ,
    lastUserEvent  = 0x7FFF
} eventsEnum;
```

Each of these event types is discussed in alphabetical order below.

## **EventType**

The `EventType` structure contains all the data associated with a system event. All event types have some common data. Most events also have data specific to those events. The specific data uses a union that is part of the `EventType` data structure. The union can have up to 8 words of specific data.

The common data is documented below the structure. The [Event Reference](#) section gives details on the important data associated with each type of event.

## Palm OS Events

### Event Data Structures

---

```
typedef struct {
    eventsEnum    eType;
    Boolean        penDown;
    UInt8         tapCount;
    Int16         screenX;
    Int16         screenY;
    union{
        ...
    } data;
} EventType;
```

#### Common Field Descriptions

eType	One of the <a href="#">eventsEnum</a> constants. Specifies the type of the event.
penDown	true if the pen was down at the time of the event, otherwise false.
tapCount	The number of taps received at this location. This value is used mainly by fields. When the user taps in a text field, two taps selects a word, and three taps selects the entire line.
screenX	Window-relative position of the pen in pixels (number of pixels from the left bound of the window).
screenY	Window-relative position of the pen in pixels (number of pixels from the top left of the window).
data	The specific data for an event, if any. The data is a union, and its exact contents depend on the eType field. The <a href="#">Event Reference</a> section in this chapter shows what the data field contains for each event.

---

**NOTE:** Remember that the `data` field is part of the access path to an identifier in the `EventType` structure. As an example, the code to access the `controlID` field of a `ctlEnterEvent` would be:

```
EventType *event;  
//...  
if (event->data.ctlEnter.controlID ==  
    MyAppLockButton)
```

---

### **Compatibility**

The `tapCount` field is only defined if [3.5 New Feature Set](#) is present. Because of the `tapCount` field, it's particularly important that you clear the event structure before you use it to add a new event to the queue in Palm OS 3.5 and higher. Otherwise, the `tapCount` value may be incorrect for the new event.

### **EventPtr**

The `EventPtr` defines a pointer to an [EventType](#).

```
typedef EventType *EventPtr;
```

## **Event Reference**

### **appStopEvent**

When the system wants to launch a different application than the one currently running, the event manager sends this event to request the current application to terminate. In response, an application has to exit its event loop, close any open files and forms, and exit.

If an application doesn't respond to this event by exiting, the system can't start the other application.

## ctlEnterEvent

The control routine [CtlHandleEvent](#) sends this event when it receives a [penDownEvent](#) within the bounds of a control.

For this event, the data field contains the following structure:

```
struct ctlEnter {
    UInt16 controlID;
    struct ControlType *pControl;
} ctlEnter;
```

### Field Descriptions

`controlID` Developer-defined ID of the control.

`pControl` Pointer to a control structure ([ControlType](#)).

## ctlExitEvent

The control routine [CtlHandleEvent](#) sends this event. When [CtlHandleEvent](#) receives a [ctlEnterEvent](#), it tracks the pen until the pen is lifted from the display. If the pen is lifted within the bounds of a control, a [ctlSelectEvent](#) is added to the event queue; if not, a [ctlExitEvent](#) is added to the event queue. The `penDown`, `screenX`, and `screenY` fields of the [EventType](#) structure are set appropriately for the [ctlExitEvent](#). As well, the data field contains the following structure:

```
struct ctlExit {
    UInt16 controlID;
    struct ControlType *pControl;
} ctlExit;
```

### Field Descriptions

`controlID` Developer-defined ID of the control.

`pControl` Pointer to a control structure ([ControlType](#)).

## ctlRepeatEvent

The control routine [CtlHandleEvent](#) sends this event. When [CtlHandleEvent](#) receives a [ctlEnterEvent](#) in a repeating

button (tREP) or a feedback slider control (tslf), it sends a `ctlRepeatEvent`. When `CtlHandleEvent` receives a `ctlRepeatEvent` in a repeating button, it sends another `ctlRepeatEvent` if the pen remains down within the bounds of the control for 1/2 second beyond the last `ctlRepeatEvent`.

When `CtlHandleEvent` receives a `ctlRepeatEvent` in a feedback slider control, it sends a `ctlRepeatEvent` each time the slider's thumb moves by at least one pixel. Feedback sliders do not send `ctlRepeatEvents` at regular intervals like repeating buttons do.

If you return `true` in response to a `ctlRepeatEvent`, it stops the `ctlRepeatEvent` loop. No further `ctlRepeatEvents` are sent.

For this event, the data field contains the following structure:

```
struct ctlRepeat {
    UInt16 controlID;
    struct ControlType *pControl;
    UInt32 time;
    UInt16 value;
} ctlRepeat;
```

### Field Descriptions

<code>controlID</code>	Developer-defined ID of the control.
<code>pControl</code>	Pointer to a control structure ( <a href="#">ControlType</a> ).
<code>time</code>	System-ticks count when the event is added to the queue.
<code>value</code>	Current value if the control is a feedback slider.

**Compatibility** The `value` field is only present if [3.5 New Feature Set](#) is present.

### ctlSelectEvent

The control routine [CtlHandleEvent](#) sends this event. When `CtlHandleEvent` receives a [ctlEnterEvent](#), it tracks the pen until the pen is lifted. If the pen is lifted within the bounds of the same control it went down in, a `ctlSelectEvent` is added to the event queue; if not, a [ctlExitEvent](#) is added to the event queue.

## Palm OS Events

### Event Reference

---

It usually doesn't matter whether you return `true` or `false` from your event handler since the operating system doesn't handle this event. The default event handler for popup triggers does handle this event, however, so you must return `false` in this instance to ensure that the list is actually displayed.

For this event, the data field contains the following structure:

```
struct ctlSelect {
    UInt16  controlId;
    struct ControlType *pControl;
    Boolean on;
    UInt8   reserved1;
    UInt16  value;
} ctlSelect;
```

#### Field Descriptions

<code>controlID</code>	Developer-defined ID of the control.
<code>pControl</code>	Pointer to a control structure ( <a href="#">ControlType</a> ).
<code>on</code>	<code>true</code> when the control is depressed; otherwise, <code>false</code> .
<code>reserved1</code>	Unused.
<code>value</code>	Current value if the control is a slider.

**Compatibility** The `value` field is only present if [3.5 New Feature Set](#) is present.

### daySelectEvent

The system-internal `DayHandleEvent` routine, which handles events in the day selector object, handles this event. When the day selector object displays a calendar month, the user can select a day by tapping on it.

This event is sent when the pen touches and is lifted from a day number.

For this event, the data field contains the following structure:

```
struct daySelect {
    struct DaySelectorType *pSelector;
```

```
    Int16 selection;  
    Boolean useThisDate;  
    UInt8 reserved1;  
} daySelect;
```

### Field Descriptions

`pSelector` Pointer to a day selector structure (`DaySelectorType`).

`selection` Not used.

`useThisDate` Set to `true` to automatically use the selected date.

`reserved1` Unused.

## fldChangedEvent

The field routine [FldHandleEvent](#) sends this event when the text of a field has or might have been scrolled. This event actually can be triggered from any call to the field code that causes scrolling to happen; most often, this happens during `FldHandleEvent`.

When `FldHandleEvent` receives a [fldEnterEvent](#), it positions the insertion point and tracks the pen until it's lifted. Text is selected (highlighted) appropriately as the pen is dragged.

For this event, the data field contains the following structure:

```
struct fldChanged {  
    UInt16 fieldID;  
    struct FieldType *pField;  
} fldChanged;
```

### Field Descriptions

`fieldID` Developer-defined ID of the field.

`pField` Pointer to a field structure (`FieldType`).

## fldEnterEvent

The field routine [FldHandleEvent](#) sends this event when the field receives a [penDownEvent](#) within the bounds of a field. For this event, the data field contains the following structure:

```
struct fldEnter {
    UInt16 fieldID;
    struct FieldType *pField;
} fldEnter;
```

#### Field Descriptions

`fieldID` Developer-defined ID of the field.

`pField` Pointer to a field structure ([FieldType](#)).

### **fldHeightChangedEvent**

Several field routines, including [FldHandleEvent](#), send this event when the number of lines in the field changes. These functions send a `fldHeightChangedEvent` to notify your application that the height of a field needs to change.

If the field is contained in a table, the table's code handles the `fldHeightChangedEvent`. If the field is directly on a form, your application code should handle the `fldHeightChangedEvent` itself. The form code does not handle the event for you.

For this event, the data field contains the following structure:

```
struct fldHeightChanged {
    UInt16 fieldID;
    struct FieldType *pField;
    Int16 newHeight;
    UInt16 currentPos;
} fldHeightChanged;
```

#### Field Descriptions

`fieldID` Developer-defined ID of the field.

`pField` Pointer to a field structure ([FieldType](#)).

`newHeight` New visible height of the field, in number of lines.

`currentPos` Current position of the insertion point.

## frmCloseEvent

The form routines [FrmGotoForm](#) and [FrmCloseAllForms](#) send this event. [FrmGotoForm](#) sends a `frmCloseEvent` to the currently active form; [FrmCloseAllForms](#) sends a `frmCloseEvent` to all forms an application has loaded into memory. If an application doesn't intercept this event, the routine [FrmHandleEvent](#) erases the specified form and releases any memory allocated for it.

For this event, the data field contains the following structure:

```
struct frmClose {
    UInt16 formID;
} frmClose;
```

### Field Descriptions

`formID` Developer-defined ID of the form.

## frmGadgetEnterEvent

The function [FrmHandleEvent](#) sends this event when there is a [penDownEvent](#) within the bounds of an extended gadget. The gadget handler function (see [FormGadgetHandlerType](#)) should handle this event.

For this event, the data field contains the following structure:

```
struct gadgetEnter {
    UInt16 gadgetID;
    struct FormGadgetType *gadgetP;
} gadgetEnter;
```

### Field Descriptions

`gadgetID` Developer-defined ID of the gadget.

`gadgetP` Pointer to the [FormGadgetType](#) object representing this gadget.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

### **frmGadgetMiscEvent**

An application may choose to send this event when it needs to pass information to an extended gadget. The [FrmHandleEvent](#) function passes `frmGadgetMiscEvents` on to the extended gadget's handler function (see [FormGadgetHandlerType](#)).

For this event, the data field contains the following structure:

```
struct gadgetMisc {
    UInt16 gadgetID;
    struct FormGadgetType *gadgetP;
    UInt16 selector;
    void *dataP;
} gadgetMisc;
```

### Field Descriptions

<code>gadgetID</code>	Developer-defined ID of the gadget.
<code>gadgetP</code>	Pointer to the <a href="#">FormGadgetType</a> object representing this gadget.
<code>selector</code>	Any necessary integer value to pass to the gadget handler function.
<code>dataP</code>	A pointer to any necessary data to pass to the gadget handler function.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## frmGotoEvent

An application may choose to send itself this event when it receives a [sysAppLaunchCmdGoto](#) launch code. `sysAppLaunchCmdGoto` is generated when the user selects a record in the global find facility. Like [frmOpenEvent](#), `frmGotoEvent` is a request that the application initialize and draw a form, but this event provides extra information so that the application may display and highlight the matching string in the form.

The application is responsible for handling this event.

For this event, the data field contains the following structure:

```
struct frmGoto {
    UInt16 formID;
    UInt16 recordNum;
    UInt16 matchPos;
    UInt16 matchLen;
    UInt16 matchFieldNum;
```

## Palm OS Events

### Event Reference

---

```
    UInt32 matchCustom;  
} frmGoto;
```

#### Field Descriptions

formID	Developer-defined ID of the form.
recordNum	Index of record containing the match string.
matchPos	Position of the match.
matchLen	Length of the matched string.
matchFieldNum	Number of the field the matched string was found in.
matchCustom	Application-specific information. You might use this if you need to provide extra information to locate the matching string within the record.

### frmLoadEvent

The form routines [FrmGotoForm](#) and [FrmPopupForm](#) send this event. It's a request that the application load a form into memory.

The application is responsible for handling this event. In response to this event, applications typically initialize the form, make it active, and set the event handler.

For this event, the data field contains the following structure:

```
struct frmLoad {  
    UInt16 formID;  
} frmLoad;
```

#### Field Descriptions

formID	Developer-defined ID of the form.
--------	-----------------------------------

### frmOpenEvent

The form routines [FrmGotoForm](#) and [FrmPopupForm](#) send this event. It is a request that the application initialize and draw a form.

The application is responsible for handling this event.

For this event, the data field contains the following structure:

```
struct frmOpen {
    UInt16 formID;
} frmOpen;
```

### **Field Descriptions**

formID     Developer-defined ID of the form.

## **frmSaveEvent**

The form routine [FrmSaveAllForms](#) sends this event. It is a request that the application save any data stored in a form.

The application is responsible for handling this event.

No data is passed with this event.

## **frmTitleEnterEvent**

The control routine [FrmHandleEvent](#) sends this event when it receives a [penDownEvent](#) within the bounds of the title of the form. Note that only the written title, not the whole title bar is active.

For this event, the data field contains the following structure:

```
struct frmTitleEnter {
    UInt16 formID;
} frmTitleEnter;
```

### **Field Descriptions**

formID             Developer-defined ID of the form.

## **frmTitleSelectEvent**

The control routine [FrmHandleEvent](#) sends this event. [FrmHandleEvent](#) receives a [frmTitleEnterEvent](#), it tracks the pen until the pen is lifted. If the pen is lifted within the bounds of the active same title bar region, a [frmTitleSelectEvent](#) is added to the event queue.

For this event, the data field contains the following structure:

```
struct frmTitleSelect {
    UInt16 formID;
} frmTitleSelect;
```

### Field Descriptions

formID            Developer-defined ID of the form.

**Compatibility**    In Palm OS version 3.5 and higher, [FrmHandleEvent](#) responds to `frmTitleSelectEvent`. Its response is to enqueue a [keyDownEvent](#) with a `vchrMenu` character to display the form's menu.

### frmUpdateEvent

The form routine [FrmUpdateForm](#), or in some cases the routine [FrmEraseForm](#), sends this event when it needs to redraw the region obscured by the form being erased.

Generally, the region obscured by a form is saved and restored by the form routines without application intervention. However, in cases where the system is running low on memory, the form's routine may not save obscured regions itself. In that case, the application adds a `frmUpdateEvent` to the event queue. The form receives the event and redraws the region using the `updateCode` value.

An application can define its own `updateCode` and then use this event to also trigger behavior in another form, usually when changes made to one form need to be reflected in another form.

For this event, the data field contains the following structure:

```
struct frmUpdate {
    UInt16 formID;
    UInt16 updateCode;
} frmUpdate;
```

### Field Descriptions

formID	Developer-defined ID of the form.
updateCode	The reason for the update request. FrmEraseForm sets this code to frmRedrawUpdateCode, which indicates that the entire form needs to be redrawn. Application developers can define their own updateCode. The updateCode is passed as a parameter to <a href="#">FrmUpdateForm</a> .

## inetSockReadyEvent

This event is returned only by [INetLibGetEvent](#) (not [EvtGetEvent](#)) when the Internet library determines that a socket has data ready for an [INetLibSockRead](#).

For this event, the data field contains the following structure:

```
struct {
    MemHandle  sockH;
    UInt32     context;
    Boolean    inputReady;
    Boolean    outputReady;
} inetSockReady;
```

### Field Descriptions

sockH	Socket handle of the socket that this event refers to.
context	Not used.
inputReady	true when the socket has data ready for the <a href="#">INetLibSockRead</a> call.
outputReady	Not used.

The penDown, tapCount, screenX and screenY fields are **not** valid for Internet library events and should be ignored.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

### inetSockStatusChangeEvent

This event is returned only by [INetLibGetEvent](#) (not `EvtGetEvent`) when the Internet library determines that a socket has data ready for an [INetLibSockRead](#).

For this event, the data field contains the following structure:

```
struct {
    MemHandle  sockH;
    UInt32     context;
    UInt16     status;
    Err        sockErr;
}inetSockStatusChange;
```

#### Field Descriptions

sockH	Socket handle of the socket that this event refers to.
context	Not used.
status	Current status of the socket. This is one of the <a href="#">INetStatusEnum</a> constants.
sockErr	Reason for failure of the last operation, if any. The current socket error can be cleared by calling <a href="#">INetLibSockStatus</a> .

The `penDown`, `tapCount`, `screenX` and `screenY` fields are **not** valid for Internet library events and should be ignored.

**Compatibility** Implemented only if [Wireless Internet Feature Set](#) is present.

### keyDownEvent

This event is sent by the system when the user enters a Graffiti<sup>®</sup> character, presses one of the buttons below the display, or taps one of the icons in the icon area; for example, the Find icon.

For this event, the data field contains the following structure:

```
struct _KeyDownEventType {
    WChar    chr;
    UInt16   keyCode;
    UInt16   modifiers;
};
```

### **Field Descriptions**

chr	The character code.
keyCode	Unused.
modifiers	0, or one or more of the following values:
shiftKeyMask	Graffiti is in case-shift mode.
capsLockMask	Graffiti is in cap-shift mode.
numLockMask	Graffiti is in numeric-shift mode.
commandKeyMask	The Graffiti glyph was the menu command glyph or a virtual key code.
optionKeyMask	Not implemented. Reserved.
controlKeyMask	Not implemented. Reserved.
autoRepeatKeyMask	Event was generated due to auto-repeat.
doubleTapKeyMask	Not implemented. Reserved.
poweredOnKeyMask	The key press caused the system to be powered on.
appEvtHookKeyMask	System use only.
libEvtHookKeyMask	System use only.

### **lstEnterEvent**

The list routine [LstHandleEvent](#) sends this event when it receives a [penDownEvent](#) within the bounds of a list object.

For this event, the data field contains the following structure:

## Palm OS Events

### Event Reference

---

```
struct lstEnter {
    UInt16 listID;
    struct ListType *pList;
    Int16 selection;
} lstEnter;
```

#### Field Descriptions

listID Developer-defined ID of the list.

pList Pointer to a list structure ([ListType](#)).

selection Unused.

### lstExitEvent

The list routine [LstHandleEvent](#) sends this event. When [LstHandleEvent](#) receives a [lstEnterEvent](#), it tracks the pen until the pen is lifted. If the pen is lifted within the bounds of a list, a [lstSelectEvent](#) is added to the event queue; if not, a [lstExitEvent](#) is added to the event queue.

For this event, the data field contains the following structure:

```
struct lstExit {
    UInt16 listID;
    struct ListType *pList;
} lstExit;
```

#### Field Descriptions

listID Developer-defined ID of the list.

pList Pointer to a list structure ([ListType](#)).

### lstSelectEvent

The list routine [LstHandleEvent](#) sends this event. When [LstHandleEvent](#) receives a [lstEnterEvent](#), it tracks the pen until the pen is lifted. If the pen is lifted within the bounds of a list, a [lstSelectEvent](#) is added to the event queue; if not, a [lstExitEvent](#) is added to the event queue.

Note that popup lists don't generate a `lstSelectEvent`. Instead, they generate a `popSelectEvent`.

For this event, the data field contains the following structure:

```
struct lstSelect {
    UInt16 listID;
    struct ListType *pList;
    Int16 selection;
} lstSelect;
```

### Field Descriptions

`listID` Developer-defined ID of the list.

`pList` Pointer to a list structure ([ListType](#)).

`selection` Item number (zero-based) of the new selection.

## menuCloseEvent

This event is not currently used.

## menuCmdBarOpenEvent

The menu routine [MenuHandleEvent](#) sends this event when the user enters the menu shortcut keystroke, causing the command toolbar to be displayed at the bottom of the screen. Applications might respond to this event by calling [MenuCmdBarAddButton](#) to add custom buttons to the command toolbar. Shared libraries or other non-application code resources can add buttons to the toolbar by registering to receive the [sysNotifyMenuCmdBarOpenEvent](#) notification.

For this event, the data field contains the following structure:

```
struct menuCmdBarOpen {
    Boolean preventFieldButtons;
    UInt8 reserved;
} menuCmdBarOpen;
```

### Field Descriptions

`preventFieldButtons` If `true`, the field manager does not add the standard cut, copy, paste, and undo buttons when the focus is on a field. If `false`, the field adds the buttons.

`reserved` Unused.

To prevent the command toolbar from being displayed, respond to this event and return `true`. Returning `true` prevents the form manager from displaying the toolbar.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

### menuEvent

The menu routine [MenuHandleEvent](#) sends this event:

- When the user selects an item from a pull-down menu
- When the user selects a menu command using the Graffiti command keystroke followed by an available command; for example, Command-C for copy
- When the user taps one of the buttons on the command toolbar and the button is set up to generate a `menuEvent`.

For this event, the data field contains the following structure:

```
struct menu {
    UInt16 itemID;
} menu;
```

### Field Descriptions

`itemID` Item ID of the selected menu command.

### menuOpenEvent

The menu routine [MenuHandleEvent](#) sends this event when a new active menu has been initialized. A menu becomes active the first time the user taps the Menu silk-screen button or taps the form's titlebar, and it might need to be re-initialized and reactivated several times during the life of an application.

A menu remains active until one of the following happens:

- A [FrmSetMenu](#) call changes the active menu on the form.
- A new form, even a modal form or alert panel, becomes active.

Suppose a user selects your application's About item from the Options menu then clicks the OK button to return to the main form. When the About dialog is displayed, it becomes the active form, which causes the main form's menu state to be erased. This menu state is not restored when the main form becomes active again. The next time the user requests the menu, it must be initialized again, so `menuOpenEvent` is sent again.

Applications might respond to this event by adding, hiding, or un-hiding menu items using the functions [MenuAddItem](#), [MenuHideItem](#), or [MenuShowItem](#).

A `menuCloseEvent` is defined by the system, but it is not currently sent. If you need to perform some cleanup (such as closing a resource) after the menu item you added is no longer needed, do so in response to [frmCloseEvent](#).

For this event, the data field contains the following structure:

```
struct menuOpen {
    UInt16    menuRscID;
    Int16     cause;
} menuOpen;
```

### Field Descriptions

`menuRscID` Resource ID of the menu.

`cause` Reason for opening the menu. If `menuButtonCause`, the user tapped the Menu silkscreen button or tapped the form's titlebar, and the menu is going to be displayed. If `menuCommandCause`, the user entered the command keystroke, so the menu is becoming active without being displayed.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

### nilEvent

A `nilEvent` is useful for animation, polling, and similar situations. The event manager sends this event when there are no events in the event queue. This can happen if the routine `EvtGetEvent` is passed a time-out value (a value other than `evtWaitForever`, -1). If `EvtGetEvent` is unable to return an event in the specified time, it returns a `nilEvent`. Different Palm OS versions and different devices can send `nilEvents` under different circumstances, so you might receive a `nilEvent` even before the timeout has expired.

### penDownEvent

The event manager sends this event when the pen first touches the digitizer.

The following data is passed with the event:

#### Field Descriptions

<code>penDown</code>	Always <code>true</code> .
<code>tapCount</code>	The number of taps received at this location.
<code>screenX</code>	Window-relative position of the pen in pixels (number of pixels from the left bound of the window).
<code>screenY</code>	Window-relative position of the pen in pixels (number of pixels from the top left of the window).

### penMoveEvent

The event manager sends this event when the pen is moved on the digitizer. Note that several kinds of UI objects, such as controls and lists, track the movement directly, and no `penMoveEvent` is generated.

The following data is passed with the event:

#### Field Descriptions

<code>penDown</code>	Always <code>true</code> .
<code>tapCount</code>	The number of taps received at this location.

`screenX` Window-relative position of the pen in pixels (number of pixels from the left bound of the window).

`screenY` Window-relative position of the pen in pixels (number of pixels from the top left of the window).

## **penUpEvent**

The event manager sends this event when the pen is lifted from the digitizer. Note that several kinds of UI objects, such as controls and lists, track the movement directly, and no `penUpEvent` is generated.

For this event, the data field contains the following structure:

```
struct _PenUpEventType {
    PointType start;
    PointType end;
};
```

### **Field Descriptions**

`start` Display-relative start point of the stroke.

`end` Display-relative end point of the stroke.

In addition, the following data is passed with this event:

`penDown` Always false.

`tapCount` The number of taps received at this location.

`screenX` Window-relative position of the pen in pixels (number of pixels from the left bound of the window).

`screenY` Window-relative position of the pen in pixels (number of pixels from the top left of the window).

## **popSelectEvent**

The form routine [FrmHandleEvent](#) sends this event when the user selects an item in a popup list.

For this event, the data field contains the following structure:

## Palm OS Events

### Event Reference

---

```
struct popSelect {
    UInt16 controlID;
    struct ControlType *controlP;
    UInt16 listID;
    struct ListType *listP;
    Int16 selection;
    Int16 priorSelection;
} popSelect;
```

#### Field Descriptions

controlID	Developer-defined ID of the resource.
controlP	Pointer to the control structure ( <a href="#">ControlType</a> ) of the popup trigger object.
listID	Developer-defined ID of the popup list object.
listP	Pointer to the list structure ( <a href="#">ListType</a> ) of the popup list object.
selection	Item number (zero-based) of the new list selection.
priorSelection	Item number (zero-based) of the prior list selection.

#### sclEnterEvent

The routine [SclHandleEvent](#) sends this event when it receives a `penDownEvent` within the bounds of a scroll bar.

Applications usually don't have to handle this event.

For this event, the data field contains the following structure:

```
struct sclEnter {
    UInt16 scrollBarID;
    struct ScrollBarType *pScrollBar;
} sclEnter;
```

### Field Descriptions

scrollBarID	Developer-defined ID of the scroll bar resource.
pScrollBar	Pointer to the scroll bar structure.

### sclExitEvent

The routine [SclHandleEvent](#) sends this event when the user lifts the pen from the scroll bar.

Applications that want to implement non-dynamic scrolling should wait for this event, then scroll the text using the values provided in value and newvalue.

Note that this event is sent regardless of previous sclRepeatEvents. If, however, the application has implemented dynamic scrolling, it doesn't have to catch this event.

For this event, the data field contains the following structure:

```
struct sclExit {
    UInt16 scrollBarID;
    struct ScrollBarType *pScrollBar;
    Int16 value;
    Int16 newValue;
} sclExit;
```

### Field Descriptions

scrollBarID	Developer-defined ID of the scroll bar resource.
pScrollBar	Pointer to the scroll bar structure.
value	Initial position of the scroll bar
newvalue	New position of the scroll bar. Given value and newValue, you can actually tell how much you have scrolled.

### sclRepeatEvent

The routine [SclHandleEvent](#) sends this event when the pen is continually held within the bounds of a scroll bar.

## Palm OS Events

### Event Reference

---

Applications that implement dynamic scrolling should watch for this event. In dynamic scrolling, the display is updated as the user drags the scroll bar (not after the user releases the scroll bar).

For this event, the data field contains the following structure:

```
struct sclRepeat {
    UInt16 scrollBarID;
    struct ScrollBarType *pScrollBar;
    Int16 value;
    Int16 newValue;
    Int32 time;
} sclRepeat;
```

#### Field Descriptions

scrollBarID	Developer-defined ID of the scroll bar resource.
pScrollBar	Pointer to the scroll bar structure.
value	Initial position of the scroll bar.
newValue	New position of the scroll bar. Given value and newValue, you can actually tell how much you have scrolled.
time	System-ticks count when the event is added to the queue to determine when the next event should occur.

#### tblEnterEvent

The table routine [TblHandleEvent](#) sends this event when it receives a [penDownEvent](#) within the bounds of an active item in a table object.

For this event, the data field contains the following structure:

```
struct tblEnter {
    UInt16 tableID;
    struct TableType *pTable;
    Int16 row;
    Int16 column;
} tblEnter;
```

### Field Descriptions

tableID	Developer-defined ID of the table.
pTable	Pointer to a table structure ( <a href="#">TableType</a> ).
row	Row of the item.
column	Column of the item.

### tblExitEvent

The table routine [TblHandleEvent](#) sends this event. When [TblHandleEvent](#) receives a [tblEnterEvent](#), it tracks the pen until it's lifted from the display. If the pen is lifted within the bounds of the same item it went down in, a [tblSelectEvent](#) is added to the event queue; if not, a [tblExitEvent](#) is added to the event queue.

For this event, the data field contains the following structure:

```
struct tblExit {
    UInt16 tableID;
    struct TableType *pTable;
    Int16 row;
    Int16 column;
} tblExit;
```

### Field Descriptions

tableID	Developer-defined ID of the table.
pTable	Pointer to a table structure ( <a href="#">TableType</a> ).
row	Row of the item.
column	Column of the item.

### tblSelectEvent

The table routine [TblHandleEvent](#) sends this event. When [TblHandleEvent](#) receives a [tblEnterEvent](#), it tracks the pen until the pen is lifted from the display. If the pen is lifted within the bounds of the same item it went down in, a [tblSelectEvent](#) is

## Palm OS Events

### Event Reference

---

added to the event queue; if not, a [tblExitEvent](#) is added to the event queue.

For this event, the data field contains the following structure:

```
struct tblSelect {
    UInt16 tableID;
    struct TableType *pTable;
    Int16 row;
    Int16 column;
} tblSelect;
```

#### Field Descriptions

tableID Developer-defined ID of the table.

pTable Pointer to a table structure ([TableType](#)).

row Row of the item.

column Column of the item.

## winEnterEvent

The event manager sends this event when a window becomes the active window. This can happen in two ways: a call to [WinSetActiveWindow](#) is issued ([FrmSetActiveForm](#) calls this routine), or the user taps within the bounds of a window that is visible but not active. All forms are windows, but not all windows are forms; for example, the menu bar is a window but not a form.

For this event, the data field contains the following structure:

```
struct _WinEnterEventType {
    WinHandle enterWindow;
    WinHandle exitWindow;
};
```

### Field Descriptions

- `enterWindow` Handle to the window we are entering. If the window is a form, then this is a pointer to a [FormType](#) structure; if not, it's a pointer to a [WindowType](#) structure.
- `exitWindow` Handle to the window we are exiting, if there is currently an active window, or zero if there is no active window. If the window is a form, then this is a pointer to a [FormType](#) structure; if not, it's a pointer to a [WindowType](#) structure.

### winExitEvent

This event is sent by the event manager when a window is deactivated. A window is deactivated when another window becomes the active window (see [winEnterEvent](#)).

For this event, the data field contains the following structure:

```
struct _WinExitEventType {
    WinHandle enterWindow;
    WinHandle exitWindow;
};
```

### Field Descriptions

- `enterWindow` Handle to the window we are entering. If the window is a form, then this is a pointer to a [FormType](#) structure; if not, it's a pointer to a [WindowType](#) structure.
- `exitWindow` Handle to the window we are exiting. If the window is a form, then this is a pointer to a [FormType](#) structure; if not, it's a pointer to a [WindowType](#) structure.

## **Palm OS Events**

*Event Reference*

---

# Notifications

---

This chapter provides detailed information about the notifications declared in the header file `NotifyMgr.h`. Notifications are broadcast to inform applications, shared libraries, system extensions, or other code resources of certain system-level or application-level events.

Notifications are similar to application launch codes, but they differ from launch codes in the following ways:

- The system broadcasts notifications only to interested parties. To register to receive a notification, use [SysNotifyRegister](#).
- Notifications can be sent to non-applications.

See the “[Notification Manager](#)” chapter in this book and the section “[Notifications](#)” on page 30 of the *Palm OS Programmer’s Companion*, vol. I for more information on receiving and handling notifications.

**Table 3.1 Notification Constants**

Constant	Description
<a href="#">cncNotifyProfileEvent</a>	The connection profile used by the Connection Panel has changed.
<a href="#">sysExternalConnectorAttachEvent</a>	A device has been attached to an external connector.
<a href="#">sysExternalConnectorDetachEvent</a>	A device has been detached from an external connector.
<a href="#">sysNotifyAntennaRaisedEvent</a>	The antenna has been raised on a Palm VII™ series device.
<a href="#">sysNotifyAppLaunchingEvent</a>	An application is about to be launched.
<a href="#">sysNotifyAppQuittingEvent</a>	An application has just quit.

## Notifications

---

**Table 3.1 Notification Constants (*continued*)**

<b>Constant</b>	<b>Description</b>
<a href="#"><u>sysNotifyCardInsertedEvent</u></a>	An expansion card has been inserted into the expansion slot.
<a href="#"><u>sysNotifyCardRemovedEvent</u></a>	An expansion card has been removed from the expansion slot.
<a href="#"><u>sysNotifyDBCreatedEvent</u></a>	A database has been created.
<a href="#"><u>sysNotifyDBChangedEvent</u></a>	Database info has been set on a database, such as with <a href="#"><u>DmSetDatabaseInfo</u></a> .
<a href="#"><u>sysNotifyDBDeletedEvent</u></a>	A database has been deleted.
<a href="#"><u>sysNotifyDBDirtyEvent</u></a>	A database has been opened for write or in some other way has been made modifiable.
<a href="#"><u>sysNotifyDeleteProtectedEvent</u></a>	The Launcher has attempted to delete a protected database.
<a href="#"><u>sysNotifyDeviceUnlocked</u></a>	The user has unlocked the device.
<a href="#"><u>sysNotifyDisplayChangeEvent</u></a>	The color table or bit depth has changed.
<a href="#"><u>sysNotifyEarlyWakeupEvent</u></a>	The system is starting to wake up.
<a href="#"><u>sysNotifyEventDequeuedEvent</u></a>	An event has been removed from the event queue with <code>EvtGetEvent</code> .
<a href="#"><u>sysNotifyForgotPasswordEvent</u></a>	The user has tapped the Lost Password button in the Security application.
<a href="#"><u>sysNotifyGotUsersAttention</u></a>	The Attention Manager has informed the user of an event.
<a href="#"><u>sysNotifyHelperEvent</u></a>	An application has requested that a particular service be performed.
<a href="#"><u>sysNotifyIdleTimeEvent</u></a>	The system is idle and is about to doze.

Table 3.1 Notification Constants (*continued*)

Constant	Description
<a href="#"><u>sysNotifyInsPtEnableEvent</u></a>	The insertion point is being enabled or disabled.
<code>sysNotifyIrDASniffEvent</code>	Not used.
<a href="#"><u>sysNotifyKeyboardDialogEvent</u></a>	The keyboard dialog is about to be displayed.
<a href="#"><u>sysNotifyLateWakeupEvent</u></a>	The system has finished waking up.
<a href="#"><u>sysNotifyLocaleChangedEvent</u></a>	The system locale has changed.
<a href="#"><u>sysNotifyMenuCmdBarOpenEvent</u></a>	The system is about to display the menu command toolbar.
<a href="#"><u>sysNotifyNetLibIFMediaEvent</u></a>	The system has been connected to or disconnected from the network.
<code>sysNotifyPhoneEvent</code>	Reserved for future use.
<code>sysNotifyPOSEMountEvent</code>	System use only.
<a href="#"><u>sysNotifyProcessPenStrokeEvent</u></a>	The user has made a pen stroke on the silkscreen portion of the digitizer.
<a href="#"><u>sysNotifyResetFinishedEvent</u></a>	The system has finished a reset.
<a href="#"><u>sysNotifyRetryEnqueueKey</u></a>	The Attention Manager has failed to post a virtual character to the key queue.
<a href="#"><u>sysNotifySleepNotifyEvent</u></a>	The system is about to go to sleep.
<a href="#"><u>sysNotifySleepRequestEvent</u></a>	The system has decided to go to sleep.
<a href="#"><u>sysNotifySyncFinishEvent</u></a>	A HotSync <sup>®</sup> operation has just completed.
<a href="#"><u>sysNotifySyncStartEvent</u></a>	A HotSync operation is about to begin.
<a href="#"><u>sysNotifyTimeChangeEvent</u></a>	The system time has just changed.
<a href="#"><u>sysNotifyVirtualCharHandlingEvent</u></a>	A virtual character is being handled.

## Notifications

### Notification Data Structures

---

**Table 3.1 Notification Constants (continued)**

Constant	Description
<a href="#"><code>sysNotifyVolumeMountedEvent</code></a>	A file system has been mounted.
<a href="#"><code>sysNotifyVolumeUnmountedEvent</code></a>	A file system has been unmounted.

---

## Notification Data Structures

### SysNotifyParamType

The `SysNotifyParamType` structure contains all of the data associated with a notification. This structure is passed as the parameter block for the [`sysAppLaunchCmdNotify`](#) launch code or as a parameter to the notification callback function. All notifications have some common data. Most notifications also have data specific to that notification. The specific data is pointed to by the `notifyDetailsP` field.

The common data for each notification is documented below the following structure declaration. The [Notification Reference](#) section gives details on the important data associated with each type of notification.

```
typedef struct SysNotifyParamType {
    UInt32    notifyType;
    UInt32    broadcaster;
    void *    notifyDetailsP;
    void *    userDataP;
    Boolean   handled;
    UInt8     reserved2;
} SysNotifyParamType;
```

### Field Descriptions

<code>notifyType</code>	The type of event that occurred. See <a href="#">Notification Reference</a> .
<code>broadcaster</code>	The creator ID of the application that broadcast the notification, or <code>sysNotifyBroadcasterCode</code> if the system broadcast the event.
<code>notifyDetailsP</code>	Pointer to data specific to this notification.
<code>userDataP</code>	Custom data that your notification handler requires. You create this data and pass it to <a href="#">SysNotifyRegister</a> .
<code>handled</code>	Set to <code>true</code> if the notification has been handled; set to <code>false</code> otherwise. In some cases, <code>handled</code> is treated as a bit field that notification handlers can use to indicate that certain conditions are true.
<code>reserved2</code>	Reserved for future use.

## Notification Reference

### **cncNotifyProfileEvent**

The `cncNotifyProfileEvent` is broadcast whenever a connection profile has been created, modified, or deleted and after a request has been made to update the connection profile list.

The `notifyDetailsP` field informs the notification handler of the type of change that was made. Register for the `cncNotifyProfileEvent` if your application maintains its own list of connection profiles that it should keep current or if it should help the Connection Panel maintain its list.

#### **cncNotifyProfileEvent Specific Data**

`notifyDetailsP` points to a `CncProfileNotifyDetailsType` structure.

## Notifications

### Notification Reference

---

<b>Prototype</b>	<pre>typedef struct _CncProfileNotifyDetailsTag {     UInt16 version;     UInt32 profileID;     UInt16 deviceKind;     UInt16 request; } CncProfileNotifyDetailsType;</pre>
<b>Fields</b>	
version	The current version of this structure. Use the <code>kCncProfileNotifyCurrentVersion</code> constant to find out what the current version is.
profileID	The ID of the modified connection profile.
deviceKind	Device kind of the profile. This can be one of the following constants: <code>kCncDeviceKindSerial</code> Serial connection profile. <code>kCncDeviceKindModem</code> Modem profile. <code>kCncDeviceKindPhone</code> Phone profile. <code>kCncDeviceKindLocalNetwork</code> LAN profile.
request	The action that was performed. This can be one of the following constants: <code>kCncNotifyCreateRequest</code> The profile has been created. <code>kCncNotifyDeleteRequest</code> The profile is about to be deleted. <code>kCncNotifyModifyRequest</code> The profile has been modified.

`kCncNotifyUpdateListRequest`

A HotSync operation or system reset has just occurred. The notification handler should update the Connection Panel's list.

If a profile has been created or modified, the `request` field also contains a flag indicating how the current profile is to be set:

`kCncBecomeCurrentModifier`

The new profile should be made the current profile.

`kCncNotifyAlertUserModifier`

The user is prompted to set the current profile.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## **sysExternalConnectorAttachEvent**

The `sysExternalConnectorAttachEvent` is broadcast when a USB cradle, RS-232 cradle or peripheral, a power cable, or a modem is attached to the universal connector. This notification is broadcast only on devices that have the universal connector.

### **sysExternalConnectorAttachEvent Specific Data**

The `notifyDetailsP` field points to a `UInt16` that identifies which type of device was attached.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## **sysExternalConnectorDetachEvent**

The `sysExternalConnectorDetachEvent` is broadcast when a USB cradle, a RS-232 cradle or peripheral, a power cable, or a modem is detached from the universal connector. This notification is only broadcast on devices that have the universal connector.

## Notifications

### Notification Reference

---

#### **sysExternalConnectorDetachEvent Specific Data**

The `notifyDetailsP` field points to a `UInt16` that identifies which type of device was detached.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

#### **sysNotifyAntennaRaisedEvent**

The `sysNotifyAntennaRaisedEvent` is broadcast by [SysHandleEvent](#) when the antenna is raised on a Palm VII series device.

Register for this notification if you want to handle the antenna key down event. To ensure that no other code handles the antenna key down event after yours, set the `handled` parameter of the [SysNotifyParamType](#) structure to `true`.

#### **sysNotifyAntennaRaisedEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

#### **sysNotifyAppLaunchingEvent**

The `sysNotifyAppLaunchingEvent` is broadcast before an application is launched with `sysAppLaunchCmdNormalLaunch`.

#### **sysNotifyAppLaunchingEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyAppLaunchOrQuitType` structure.

**Prototype**

```
typedef struct SysNotifyAppLaunchOrQuitTag {
    UInt32    version;
    UInt32    dbID;
    UInt16    cardNo;
} SysNotifyAppLaunchOrQuitType;
```

**Fields**

<code>version</code>	The current version of this structure. The current version is 0.
----------------------	--

<code>dbID</code>	The local ID of the application.
<code>cardNo</code>	The number of the card on which the application resides.

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don't broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

### **sysNotifyAppQuittingEvent**

The `sysNotifyAppQuittingEvent` is broadcast right after an application that was launched with `sysAppLaunchCmdNormalLaunch` quits.

#### **sysNotifyAppLaunchingEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyAppLaunchOrQuitType` structure. See the description of [sysNotifyAppLaunchingEvent](#) for a description of this structure.

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don't broadcast this notification. Palm OS 5 does broadcast it. Later versions Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

### **sysNotifyCardInsertedEvent**

The `sysNotifyCardInsertedEvent` is broadcast when an Expansion Manager card is inserted into a slot. When a new card is inserted, the Expansion Manager attempts to mount the volume on that card and plays a sound (indicating success or failure) once the attempt is complete.

Most applications will want to register for [sysNotifyVolumeMountedEvent](#) instead of this notification. Register for `sysNotifyCardInsertedEvent` if you need to know when a card is inserted or if you want to prevent the Expansion Manager from performing its default handling of the notification.

## Notifications

### Notification Reference

---

To prevent the Expansion Manager from mounting the volume, set the `expHandledVolume` bit in the `handled` field. To prevent the Expansion Manager from playing the sound, set the `expHandledSound` bit in the `handled` field. For example:

```
cmdPBP->handled |= expHandledSound;
```

#### **sysNotifyCardInsertedEvent Specific Data**

`notifyDetailsP` points to a `UInt16` containing the slot reference number.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

#### **sysNotifyCardRemovedEvent**

The `sysNotifyCardRemovedEvent` is broadcast when an Expansion Manager card is removed from a slot. When a card is removed, the Expansion Manager responds to this notification by playing a goodbye sound and then attempting to unmount the volume.

Most applications will want to register for [sysNotifyVolumeUnmountedEvent](#) instead of this notification. Register for `sysNotifyCardRemovedEvent` if you need to know when a card is removed or if you want to prevent the Expansion Manager from performing its default handling of the notification.

To prevent the Expansion Manager from unmounting the volume, set the `expHandledVolume` bit in the `handled` field. To prevent the Expansion Manager from playing the sound, set the `expHandledSound` bit in the `handled` field. For example:

```
cmdPBP->handled |= expHandledSound;
```

#### **sysNotifyCardRemovedEvent Specific Data**

`notifyDetailsP` points to a `UInt16` containing the slot reference number.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

---

## **sysNotifyDBCreatedEvent**

The `sysNotifyDBCreatedEvent` is broadcast sometime *after* a database is created with [DmCreateDatabase](#).

Register for this notification if you keep an internal list of databases that needs to be updated when a new database is created.

---

**IMPORTANT:** The `sysNotifyDBxxxEvent` notifications are deferred notifications. So, for instance, if your application creates a database, opens it for write, and then renames it, all before `EvtGetEvent` is called, the three corresponding notifications will all go out together. A `sysNotifyDBDirtyEvent` handler would fail if it tried to open the database, since the database will already have been renamed. You must be aware of the ramifications of a deferred notification when writing your notification handler.

---

### **sysNotifyDBCreatedEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyDBCreatedType` structure.

**Prototype**

```
typedef struct SysNotifyDBCreatedTag {
    Char dbName [dmDBNameLength];
    UInt32 creator;
    UInt32 type;
    LocalID newDBID;
    UInt16 cardNo;
    Boolean resDB;
    UInt8 padding;
} SysNotifyDBCreatedType;
```

<b>Fields</b>	<code>dbName</code>	Database name.
	<code>creator</code>	Database creator ID.
	<code>type</code>	Database type.
	<code>newDBID</code>	Local ID of the newly-created database.

## Notifications

### Notification Reference

---

<code>cardno</code>	Card number upon which the database resides.
<code>resDB</code>	<code>true</code> if the database is a resource database, <code>false</code> otherwise.
<code>padding</code>	Structure padding byte.

**Compatibility** Implemented only if [5.0 New Feature Set](#) is present.

**New**

---

### **sysNotifyDBChangedEvent**

The `sysNotifyDBChangedEvent` is broadcast sometime *after* database info is set with [DmSetDatabaseInfo](#).

Register for this notification if you keep an internal list of databases that needs to be updated when database info changes.

---

**IMPORTANT:** The `sysNotifyDBxxxEvent` notifications are deferred notifications. So, for instance, if your application creates a database, opens it for write, and then renames it, all before `EvtGetEvent` is called, the three corresponding notifications will all go out together. A `sysNotifyDBDirtyEvent` handler would fail if it tried to open the database, since the database will already have been renamed. You must be aware of the ramifications of a deferred notification when writing your notification handler.

---

#### **sysNotifyDBChangeEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyDBChangedType` structure. The contents of `fields` in this structure indicates what about the database changed, and thus which of the other structure fields contain valid data.

**Prototype**    `typedef struct SysNotifyDBChangedTag {  
                  Char dbName[dmDBNameLength];  
                  LocalID dbID;  
                  UInt32 creator;  
                  UInt32 type;  
                  UInt32 crDate;  
                  UInt32 modDate;  
                  UInt32 bckUpDate;  
                  UInt32 modNum;  
                  LocalID appInfoID;  
                  LocalID sortInfoID;  
                  UInt16 attributes;  
                  UInt16 cardNo;  
                  UInt16 version;  
                  UInt16 fields;  
                  Char oldName[dmDBNameLength];  
                  UInt32 oldCreator;  
                  UInt32 oldType;  
                  UInt16 oldAttributes;  
                  UInt16 padding;  
                  } SysNotifyDBChangedType;`

<b>Fields</b>	dbName	New name of database.
	dbID	Database ID.
	creator	New database creator ID.
	type	New database type.
	crDate	New database creation date.
	modDate	New database modification date.
	bckUpDate	New database backup date.
	modNum	New database modification number.
	appInfoID	New database application info block.
	sortInfoID	New database sort info block.
	attributes	New database attributes.
	cardNo	Card number upon which the dabatase resides.

## Notifications

### Notification Reference

---

version	New database version.																								
fields	Flags that indicate what about the database changed, and thus which of the above fields are set. The constants that define the <code>fields</code> bits are: <table><thead><tr><th>Flag</th><th>Value</th></tr></thead><tbody><tr><td>DBChangedFieldSetName</td><td>0x1</td></tr><tr><td>DBChangedFieldSetCreator</td><td>0x2</td></tr><tr><td>DBChangedFieldSetType</td><td>0x4</td></tr><tr><td>DBChangedFieldSetCrDate</td><td>0x8</td></tr><tr><td>DBChangedFieldSetModDate</td><td>0x10</td></tr><tr><td>DBChangedFieldSetBckUpDate</td><td>0x20</td></tr><tr><td>DBChangedFieldSetModNum</td><td>0x40</td></tr><tr><td>DBChangedFieldSetAppInfo</td><td>0x80</td></tr><tr><td>DBChangedFieldSetSortInfo</td><td>0x100</td></tr><tr><td>DBChangedFieldSetAttributes</td><td>0x200</td></tr><tr><td>DBChangedFieldSetVersion</td><td>0x400</td></tr></tbody></table>	Flag	Value	DBChangedFieldSetName	0x1	DBChangedFieldSetCreator	0x2	DBChangedFieldSetType	0x4	DBChangedFieldSetCrDate	0x8	DBChangedFieldSetModDate	0x10	DBChangedFieldSetBckUpDate	0x20	DBChangedFieldSetModNum	0x40	DBChangedFieldSetAppInfo	0x80	DBChangedFieldSetSortInfo	0x100	DBChangedFieldSetAttributes	0x200	DBChangedFieldSetVersion	0x400

oldName	Name of database prior to the call to <code>DmSetDatabaseInfo</code> .																								
oldCreator	Database creator ID prior to the call to <code>DmSetDatabaseInfo</code> .																								
oldType	Database type prior to the call to <code>DmSetDatabaseInfo</code> .																								
oldAttributes	Database attributes prior to the call to <code>DmSetDatabaseInfo</code> .																								
padding	Structure padding bytes.																								

**Compatibility** Implemented only if [5.0 New Feature Set](#) is present.

## sysNotifyDBDeletedEvent

The `sysNotifyDBDeletedEvent` is broadcast sometime *after* a database is removed from the device.

Register for this notification if you keep an internal list of databases that needs to be updated upon removal of a database. For example, the Attention Manager and Connection Manager register for this notification to maintain their internal lists of databases.

---

**IMPORTANT:** The `sysNotifyDBxxxEvent` notifications are deferred notifications. So, for instance, if your application creates a database, opens it for write, and then renames it, all before `EvtGetEvent` is called, the three corresponding notifications will all go out together. A `sysNotifyDBDirtyEvent` handler would fail if it tried to open the database, since the database will already have been renamed. You must be aware of the ramifications of a deferred notification when writing your notification handler.

---

### sysNotifyDBDeletedEvent Specific Data

`notifyDetailsP` points to a `SysNotifyDBDeletedType` structure.

**Prototype**

```
typedef struct SysNotifyDBDeletedTag {
    LocalID oldDBID;
    UInt16 cardNo;
    UInt16 attributes;
    Char dbName[dmDBNameLength];
    UInt32 creator;
    UInt32 type;
} SysNotifyDBDeletedType;
```

**Fields**

<code>oldDBID</code>	The local ID of the deleted database. This ID is no longer valid.
----------------------	---

---

**WARNING!** The ID in `oldDBID` is invalid by the time the notification is broadcast. If you try to pass it to a Data Manager function, the system will crash.

---

## Notifications

### Notification Reference

---

<code>cardNo</code>	The number of the card on which the database resided.
<code>attributes</code>	The deleted database's attributes.
<code>dbName</code>	The name of the deleted database.
<code>creator</code>	The creator ID of the deleted database.
<code>type</code>	The type of the deleted database.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

---

### **sysNotifyDBDirtyEvent**

The `sysNotifyDBDirtyEvent` is broadcast sometime *after* a database is opened for write or in some other way has been made modifiable. Note that the database may not have actually been modified yet.

Register for this notification if you keep an internal list of databases that needs to be updated when a database becomes "dirty." For instance, upon reset the Launcher normally checks over such databases and updates its internal list.

---

**IMPORTANT:** The `sysNotifyDBxxxEvent` notifications are deferred notifications. So, for instance, if your application creates a database, opens it for write, and then renames it, all before `EvtGetEvent` is called, the three corresponding notifications will all go out together. A `sysNotifyDBDirtyEvent` handler would fail if it tried to open the database, since the database will already have been renamed. You must be aware of the ramifications of a deferred notification when writing your notification handler.

---

#### **sysNotifyDBDirtyEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyDBDirtyType` structure.

**Prototype**

```
typedef struct SysNotifyDBDirtyTag {
    Char dbName[dmDBNameLength];
    UInt32 creator;
    UInt32 type;
} SysNotifyDBDirtyType;
```

**Fields**

dbName	Database name.
creator	Database creator ID.
type	Database type.

**Compatibility** Implemented only if [5.0 New Feature Set](#) is present.

## sysNotifyDeleteProtectedEvent

The `sysNotifyDeleteProtectedEvent` is broadcast when the Launcher attempts to delete a database that has the protected flag set. The Launcher broadcasts the notification and then attempts to delete the database again. Any third party application that deletes databases should broadcast this notification as well.

Register for this notification if you have a protected database but you still want to allow users to delete your application or other code resource if they choose. A notification handler should check the information in the `notifyDetailsP` struct to see if its database is the one being deleted. If so, it should respond to this notification to perform any necessary cleanup and to clear the protected flag. In this way, when the Launcher attempts to delete the database again, it will succeed. Note that if an application has multiple protected databases, this notification may be sent out more than once.

### sysNotifyDeleteProtectedEvent Specific Data

`notifyDetailsP` points to a `SysNotifyDBInfoType` structure.

**Prototype**

```
typedef struct SysNotifyDBInfoTag {
    LocalID dbID;
    UInt16 cardNo;
    UInt16 attributes;
    Char dbName[dmDBNameLength];
    UInt32 creator;
```

## Notifications

### Notification Reference

---

```
    UInt32 type;  
} SysNotifyDBInfoType;
```

<b>Fields</b>	dbID	The local ID of the database to be deleted.
	cardNo	The number of the card on which the database resides.
	attributes	The database's attributes.
	dbName	The name of the database to be deleted.
	creator	The creator ID of the database to be deleted.
	type	The type of the database to be deleted.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### sysNotifyDeviceUnlocked

The `sysNotifyDeviceUnlocked` notification is broadcast by the Security application when the user unlocks the device. The notification is broadcast immediately after the device has finished unlocking.

If you display UI in response to the [sysNotifyLateWakeUpEvent](#) notification, you should also register to receive the `sysNotifyDeviceUnlocked` notification. When a locked device receives the `sysNotifyLateWakeUpEvent`, your UI should not be displayed if the device is waiting for the user to enter the password. The `sysNotifyDeviceUnlocked` notification is broadcast after the password is entered, which indicates that the user interface is ready.

#### sysNotifyDeviceUnlocked Specific Data

None.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### sysNotifyDisplayChangeEvent

The `sysNotifyDisplayChangeEvent` is broadcast whenever the display mode changes. That is, either the color table has been set to

use a specific palette using the [WinPalette](#) function or the bit depth has changed using the [WinScreenMode](#) function.

The `notifyDetailsP` field indicates how the bit depth changed. If the two values in the struct are equal, it means that the color palette has changed instead of the bit depth.

### **sysNotifyDisplayChangeEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyDisplayChangeDetailsType` structure.

**Prototype**

```
typedef struct {
    UInt32 oldDepth;
    UInt32 newDepth;
} SysNotifyDisplayChangeDetailsType;
```

**Fields**

<code>oldDepth</code>	The old bit depth.
<code>newDepth</code>	The new bit depth.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

### **sysNotifyEarlyWakeupEvent**

The `sysNotifyEarlyWakeupEvent` is broadcast during [SysHandleEvent](#) immediately after the system has finished sleeping. The screen may still be turned off, and the system may not fully wake up. It may simply handle an alarm or a battery charger event and go back to sleep. Most applications that need notification of a wakeup event will probably want to register for [sysNotifyLateWakeupEvent](#) instead.

---

**IMPORTANT:** This notification is **not** guaranteed to be broadcast. Thus, it is not suitable for applications where external hardware must be turned on when the system is powered on.

---

### **sysNotifyEarlyWakeupEvent Specific Data**

None.

## Notifications

### Notification Reference

---

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

### **sysNotifyEventDequeuedEvent**

The `sysNotifyEventDequeuedEvent` is broadcast for each event removed from the event queue with `EvtGetEvent`.

---

**WARNING!** Be very careful about registering for this notification; it can result in significantly degraded system performance.

---

#### **sysNotifyEventDequeuedEvent Specific Data**

`notifyDetailsP` points to the dequeued event's `EventType` structure.

---

**IMPORTANT:** For speed, the event structure that `notifyDetailsP` points to uses system-native endianness. This means that you might need to byte-swap the structure's contents, depending on the endianness of the underlying operating system.

---

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don't broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

### **sysNotifyForgotPasswordEvent**

The `sysNotifyForgotPasswordEvent` is broadcast after the user taps the Lost Password button in the Security application. The notification is sent after the user has confirmed that all private records should be deleted but before the deletion actually occurs.

#### **sysNotifyForgotPasswordEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## sysNotifyGotUsersAttention

The `sysNotifyGotUsersAttention` notification is broadcast when the Attention Manager has finished displaying or sounding its attention indicators (blinking, playing sounds, vibrating, and so on).

System extensions or shared libraries should register for this notification if they want to perform some extra effect or if they simply want to be informed of when the user's attention was received.

### sysNotifyGotUsersAttention Specific Data

`notifyDetailsP` points to an `AttnNotifyDetailsType` structure.

**Prototype**

```
typedef struct {
    AttnFlagsType flags;
} AttnNotifyDetailsType;
```

**Fields**

<code>flags</code>	The attention indicators that were used to get the user's attention. See <a href="#">AttnFlagsType</a> .
--------------------	--

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## sysNotifyHelperEvent

The `sysNotifyHelperEvent` is broadcast by applications to request a service from another application. For example, the Address Book application broadcasts this notification to request that the Dial application dial a phone number. For the `sysNotifyHelperEvent`, the notification client (that is, the application or shared library that registers for the notification) is called a **helper**.

The application that broadcasts this notification specifies one of the action codes listed in [Table 35.1](#) in [Chapter 35, "Helper API."](#) These action codes request all helper applications to enumerate (list the services they perform), validate (ensure that the service will succeed), and execute (perform the action). The helper responds to the notification by returning the required data in the appropriate

## Notifications

### Notification Reference

---

portion of the `notifyDetailsP` structure and by setting the `handled` field to `true` or `false` to indicate the success or failure of the action.

For more information on this notification, see the section “[Helper Notifications](#)” on page 38 in the *Palm OS Programmer’s Companion*, vol. I.

#### **sysNotifyHelperEvent Specific Data**

`notifyDetailsP` points to a [HelperNotifyEventType](#) structure.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

#### **sysNotifyIdleTimeEvent**

The `sysNotifyIdleTimeEvent` is broadcast when the system is idle and is about to doze.

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don’t broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

#### **sysNotifyInsPtEnableEvent**

The `sysNotifyInsPtEnableEvent` is broadcast at the start of `InsPtEnable`.

#### **sysNotifyInsPtEnableEvent Specific Data**

`notifyDetailsP` points to a Boolean: the `enableIt` parameter passed to `InsPtEnable`.

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don’t broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

## **sysNotifyKeyboardDialogEvent**

The `sysNotifyKeyboardDialogEvent` is broadcast whenever the system keyboard is displayed. It is intended to enable the replacement of `SysKeyboardDialog` function's user interface.

### **sysNotifyKeyboardDialogEvent Specific Data**

`notifyDetailsP` points to the `KeyboardType` enum that indicates the mode in which the keyboard should be opened: alphabetic, numeric, or international.

### **Compatibility**

This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don't broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

## **sysNotifyLateWakeupEvent**

The `sysNotifyLateWakeupEvent` is broadcast during [SysHandleEvent](#) immediately after the device has finished waking up. This notification is sent at the late stage of wakeup, after the screen has been turned on. When this notification is broadcast, the system is guaranteed to fully wake up. Register for this notification if you need to perform startup tasks each time the system wakes up.

---

**IMPORTANT:** This notification is **not** guaranteed to be broadcast. Thus, it is unsuitable for applications where external hardware must be powered on when the device wakes up.

---

When the device receives this notification, it may be locked and waiting for the user to enter the password. If this is the case, you must wait for the user to unlock the device before you display a user interface. Therefore, if you intend to display a user interface when the device wakes up, you should make sure the device is not locked. If the device is locked, you should register for [sysNotifyDeviceUnlocked](#) notification and display your user interface when it is received. For example:

## Notifications

### Notification Reference

---

```
case sysNotifyLateWakeupEvent:
    if ((Boolean)
        PrefGetPreference(prefDeviceLocked)) {
        SysNotifyRegister(myCardNo, myDbID,
            sysNotifyDeviceUnlocked, NULL,
            sysNotifyNormalPriority, NULL);
    } else {
        HandleDeviceWakeup();
    }
case sysNotifyDeviceUnlocked:
    HandleDeviceWakeup();
```

Note that the `sysNotifyDeviceUnlocked` notification is only broadcast on Palm OS 4.0 and higher.

#### **sysNotifyLateWakeupEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

#### **sysNotifyLocaleChangedEvent**

The `sysNotifyLocaleChangedEvent` is broadcast immediately after the system locale has changed. Currently, the user has the opportunity to change the locale only when the device first starts up and after a hard reset.

RAM-based applications and other code resources should obtain locale information by passing the `prefLocale` constant to [PrefGetPreference](#). They should not register for this notification. This notification is used by the built-in applications, which respond to it by rebuilding their default databases to use the newly selected language and character set.

#### **sysNotifyLocaleChangedEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyLocaleChangedType` structure.

**Prototype**

```
typedef struct SysNotifyLocaleChangedTag {
    LmLocaleType oldLocale;
    LmLocaleType newLocale;
```

```
    } SysNotifyLocaleChangedType;
```

<b>Fields</b>	<code>oldLocale</code>	The old locale. See <a href="#">LmLocaleType</a> .
	<code>newLocale</code>	The new locale.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## sysNotifyMenuCmdBarOpenEvent

The `sysNotifyMenuCmdBarOpenEvent` is broadcast during [MenuHandleEvent](#) when it is about to display the menu shortcut command bar.

Register for this notification if you are writing a system extension (such as a “hack” installed with the HackMaster program) that needs to add a button to the menu command bar or to suppress the menu command bar. To add a button, call [MenuCmdBarAddButton](#). To suppress the command toolbar, set the `handled` field to `true`.

Applications that need to add their own buttons to the menu command bar should do so in response to a [menuCmdBarOpenEvent](#). They should **not** register for this notification because an application should only add buttons if it is already the active application. The notification is sent after the event has been received, immediately before the command toolbar is displayed.

### sysNotifyMenuCmdBarOpenEvent

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## sysNotifyNetLibIFMediaEvent

The `sysNotifyNetLibIFMediaEvent` is broadcast at the top of the event loop whenever the network interface makes the network connection active or inactive. The Network Panel uses this notification to decide whether the Connect button should be active.

## Notifications

### Notification Reference

---

Register for this notification if you need to know when the network connection is currently active.

#### **sysNotifyNetLibIFMediaEvent Specific Data**

notifyDetailsP contains a SysNotifyNetLibIFMediaType structure.

**Prototype**

```
typedef struct SysNotifyNetLibIFMediaTag {
    NetLibIFMediaEventNotificationTypeEnum eType;
    UInt32 ifCreator;
    UInt16 ifInstance;
} SysNotifyNetLibIFMediaType;
```

<b>Fields</b>	eType	One of the following values:  netIFMediaUp The network connection is active. This is usually sent after the network interface has displayed UI indicating that a connection attempt is in progress.  netIFMediaDown The network connection is inactive. This is usually sent after the network interface has brought the connection down because an inactivity timeout value was reached.
	ifCreator	Creator ID of the network interface
	ifInstance	Instance number of the network interface.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

#### **sysNotifyProcessPenStrokeEvent**

The sysNotifyProcessPenStrokeEvent is broadcast to enable custom recognition of strokes made on the silkscreen portion of the digitizer.

### **sysNotifyProcessPenStrokeEvent Specific Data**

notifyDetailsP points to a SysNotifyPenStrokeType structure.

**Prototype**

```
typedef struct SysNotifyPenStrokeTag {
    UInt32      version;
    PointType   startPt;
    PointType   endPt;
} SysNotifyPenStrokeType;
```

<b>Fields</b>	version	The current version of this structure. The current version is 0.
	startPt	Start point of stroke.
	endPt	End point of stroke.

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don't broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

### **sysNotifyResetFinishedEvent**

The sysNotifyResetFinishedEvent is broadcast immediately after the system has finished a reset.

Because the notification registry is cleared upon a reset, only internal system components use this notification. Applications that need to be informed of a system reset can respond to the [sysAppLaunchCmdSystemReset](#) launch code.

#### **sysNotifyResetFinishedEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

### **sysNotifyRetryEnqueueKey**

The sysNotifyRetryEnqueueKey notification is broadcast at the top of the event loop if the Attention Manager has attempted to post

## Notifications

### Notification Reference

---

a virtual character to the key queue and failed because the queue is full. The notification signals that the Attention Manager is going to retry enqueueing the virtual character until it is successful.

Most applications do not need to register for this notification. It is used only by the Attention Manager to schedule retries of enqueueing the virtual character. When enqueueing a virtual character fails, the Attention Manager retries at the top of the event loop. It uses this notification to schedule retries so that they occur even if the user switches applications.

#### **sysNotifyRetryEnqueueKey Specific Data**

`notifyDetailsP` points to a `WChar` containing the virtual character to be enqueued.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

#### **sysNotifySleepNotifyEvent**

The `sysNotifySleepNotifyEvent` is broadcast during [SysHandleEvent](#) immediately before the system is put to sleep. After the broadcast is complete, the system is put to sleep.

Register for this notification if you have a small amount of cleanup that needs to be performed before the system goes to sleep. It is recommended that you not perform any sort of prolonged activity, such as displaying an alert panel that requests confirmation, in response to a sleep notification. If you do, the alert might be displayed long enough to trigger another auto-off event, which could be detrimental to other handlers of this notification.

If your code is in the middle of a lengthy computation and needs to defer sleep, it should register for the [sysNotifySleepRequestEvent](#) instead.

---

**IMPORTANT:** This notification is **not** guaranteed to be broadcast. For example, if the system goes to sleep because the user removes the batteries, sleep notifications are not sent. Thus, these notifications are unsuitable for applications where external hardware must be shut off to conserve power before the system goes to sleep.

---

### **sysNotifySleepNotifyEvent Specific Data**

None.

**Compatibility**    Implemented only if [Notification Feature Set](#) is present.

## **sysNotifySleepRequestEvent**

The `sysNotifySleepRequestEvent` is broadcast during [SysHandleEvent](#) processing when the system has decided to go to sleep.

Register for this notification if you need to delay the system from going to sleep while your code performs a lengthy operation, such as disconnecting from the network. The system checks the `deferSleep` value when each notification handler returns. If it is nonzero, it cancels the sleep event.

After you defer sleep, your code is free to finish what it was doing. When it is finished, you must allow the system to continue with the sleep event. To do so, create a [keyDownEvent](#) with the `resumeSleepChr` and the command key bit set (to signal that the character is virtual) and add it to the event queue. When the system receives this event, it will again broadcast the `sysNotifySleepRequestEvent` to all clients. If `deferSleep` is 0 after all clients return, then the system knows it is safe to go to sleep, and it broadcasts the `sysNotifySleepNotifyEvent` to all of its clients.

Note that you may receive this notification several times before the system goes to sleep because notification handlers can delay the system sleep and resume it later.

## Notifications

### Notification Reference

---

---

**IMPORTANT:** This notification is **not** guaranteed to be broadcast. For example, if the system goes to sleep because the user removes the batteries, sleep notifications are not sent. Thus, these notifications are unsuitable for applications where external hardware must be shut off to conserve power before the system goes to sleep.

---

#### sysNotifySleepRequestEvent Specific Data

notifyDetailsP points to a SleepEventParamType structure.

**Prototype**

```
typedef struct {
    UInt16 reason;
    UInt16 deferSleep;
} SleepEventParamType;
```

**Fields**

reason	The reason the system is going to sleep. The possible values are:  sysSleepAutoOff The idle time limit has been reached.  sysSleepPowerButton The user pressed the power off button.  sysSleepResumed The sleep event was deferred by one of the notification handlers but has been resumed through the use of the resumeSleepChr.  sysSleepUnknown Unknown reason.
deferSleep	Initially set to 0. If a notification handler wants to defer sleep, then it should increment this value. When deferSleep is greater than 0, the system waits before going to sleep.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## **sysNotifySyncFinishEvent**

The `sysNotifySyncFinishEvent` is broadcast immediately after a `HotSync` operation has completed. Register for this notification if you need to perform post-processing after `HotSync` operations.

### **sysNotifySyncFinishEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## **sysNotifySyncStartEvent**

The `sysNotifySyncStartEvent` is broadcast immediately before a `HotSync` operation is begun. Register for this notification if you need to perform preprocessing before a `HotSync` operation.

### **sysNotifySyncStartEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## **sysNotifyTimeChangeEvent**

The `sysNotifyTimeChangeEvent` notification is broadcast just after the system time has been changed using [TimSetSeconds](#). Register for this notification if you need to know when the time has changed.

### **sysNotifyTimeChangeEvent Specific Data**

None.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## **sysNotifyVirtualCharHandlingEvent**

The `sysNotifyVirtualCharHandlingEvent` is broadcast to enable custom handling of virtual characters.

## Notifications

### Notification Reference

---

#### **sysNotifyVirtualCharHandlingEvent Specific Data**

`notifyDetailsP` points to a `SysNotifyVirtualCharHandlingType` structure.

**Prototype**

```
typedef struct SysNotifyVirtualCharHandlingTag{
    UInt32 version;
    struct _KeyDownEventType keyDown;
} SysNotifyVirtualCharHandlingType;
```

**Fields**

<code>version</code>	The current version of this structure. The current version is 0.
<code>keyDown</code>	The virtual character. See the description of the <code>keyDownEvent</code> in the Event Reference section of the <i>Palm OS Programmer's API Reference</i> for a complete description of this structure and its contents.

**Compatibility** This notification is declared in the Palm OS 4.0 SDK Update 1. Versions 4.1 and earlier of Palm OS don't broadcast this notification. Palm OS 5 does broadcast it. Later versions may or may not broadcast this notification.

#### **sysNotifyVolumeMountedEvent**

The `sysNotifyVolumeMountedEvent` is broadcast when a Virtual File System Manager volume is mounted. When a volume is mounted, the VFS Manager activates the `start.prc` application on the newly mounted volume and switches applications to the Launcher or to the `start.prc` application on that volume if it has a user interface.

Register for this notification if you need to know when a volume is mounted or if you want to prevent the default behavior of the VFS Manager.

To prevent the VFS Manager from activating the `start.prc` application, set the `vfsHandledStartPrc` bit in the `handled` field. To prevent the VFS Manager from switching applications, set the `vfsHandledUIAppSwitch` bit.

### **sysNotifyVolumeMountedEvent Specific Data**

`notifyDetailsP` points to a [VFSSlotMountParamType](#) or [VFSPoSEMountParamType](#) structure.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### **sysNotifyVolumeUnmountedEvent**

The `sysNotifyVolumeUnmountedEvent` is broadcast when a Virtual File System Manager volume is unmounted. Register for this notification if you need to know when a volume is unmounted.

### **sysNotifyVolumeUnmountedEvent Specific Data**

`notifyDetailsP` points to a `UInt16` containing the volume reference number.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **Notifications**

*Notification Reference*

---

# Attention Manager

---

This chapter provides reference material for the Attention Manager, and is divided into the following sections:

- [Attention Manager Data Structures](#)
- [Attention Manager Constants](#)
- [Attention Manager Functions](#)
- [Application-Defined Functions](#)

The Attention Manager API is declared in the header file `AttentionMgr.h`.

For more information about the attention manager, see the section “[Getting the User’s Attention](#)” in the *Palm OS Programmer’s Companion*, vol. I.

---

**IMPORTANT:** The Attention Manager was introduced in Palm OS® 4.0 and is not available in earlier versions of the operating system.

---

## Attention Manager Data Structures

### AttnCommandType

The `AttnCommandType` typedef specifies the set of possible commands that can be sent to the application requesting the user’s attention, either as a parameter to the [AttnCallbackProc](#) callback function or as one of the arguments that accompanies a [sysAppLaunchCmdAttention](#) launch code.

```
typedef UInt16 AttnCommandType;
```

The following table lists the values that `AttnCommandType` can assume.

## Attention Manager

### Attention Manager Data Structures

---

Constant	Description
<code>kAttnCommandDrawDetail</code>	Indicates that the application needs to draw the detailed contents of the attention dialog. The command arguments parameter points to a structure of type <a href="#">drawDetail</a> .
<code>kAttnCommandDrawList</code>	Indicates that the application needs to draw the appropriate list item in the attention dialog. The command arguments parameter points to a structure of type <a href="#">drawList</a> .
<code>kAttnCommandPlaySound</code>	Indicates that the application needs to play a sound. The command arguments parameter is NULL.
<code>kAttnCommandCustomEffect</code>	Indicates that the application needs to perform any application-specific special effects. This command is only sent for attention items that set the <code>kAttnFlagsCustomEffectBit</code> when they call <a href="#">AttnGetAttention</a> , which most applications won't do.
<code>kAttnCommandGoThere</code>	Tells the application to navigate to the item. The command arguments parameter is NULL. An application commonly calls <a href="#">SysAppLaunch</a> upon receipt of this command to have itself launched.
<code>kAttnCommandGotIt</code>	Tells the application that the user is dismissing the item. The command arguments parameter points to a structure of type <a href="#">gotIt</a> . The application may choose to clean up memory at this point.

<b>Constant</b>	<b>Description</b>
<code>kAttnCommandSnooze</code>	Indicates to the application that the user is snoozing. The command arguments parameter is NULL. Most applications do nothing upon receipt of this command. This command is passed to the appropriate application for each and every item currently pending, insistent or subtle. Applications with more than one attention item pending are called more than once.
<code>kAttnCommandIterate</code>	This command is passed to the application during the enumeration of attention items. It is particularly useful after HotSync <sup>®</sup> operations, as it allows the application to examine each item, updating or removing those that are stale or invalid. The command arguments parameter points to a structure of type <a href="#">iterate</a> .

---

## AttnCommandArgsType

The `AttnCommandArgsType` structure is a union of C structures. How you interpret the union's contents depends on which command it accompanies. Not all commands are accompanied by an `AttnCommandArgsType` structure, as listed in the following table:

<b>AttnCommandType</b>	<b>Accompanied By</b>
<code>kAttnCommandDrawDetail</code>	<a href="#">drawDetail</a>
<code>kAttnCommandDrawList</code>	<a href="#">drawList</a>
<code>kAttnCommandPlaySound</code>	None
<code>kAttnCommandCustomEffect</code>	None
<code>kAttnCommandGoThere</code>	None
<code>kAttnCommandGotIt</code>	<a href="#">gotIt</a>
<code>kAttnCommandSnooze</code>	None
<code>kAttnCommandIterate</code>	<a href="#">iterate</a>

---

## Attention Manager

### *Attention Manager Data Structures*

---

The structures that make up the `AttnCommandArgsType` union are described in the following sections.

#### **drawDetail**

When `kAttnCommandDrawDetail` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, the application needs to draw the detailed contents of the attention dialog. The `drawDetail` structure accompanies the `kAttnCommandDrawDetail` command, and provides the information needed to draw the contents of that dialog.

```
struct AttnCommandArgsDrawDetailTag {
    RectangleType bounds;
    Boolean firstTime;
    AttnFlagsType flags;
} drawDetail;
```

### Field Descriptions

<code>bounds</code>	Contains the window-relative bounding box for the area to draw. The clipping region is also set to the dimensions of this box to prevent accidental drawing outside.
<code>firstTime</code>	Set to <code>true</code> if the user has not yet seen this item. The value of this field could be used to display attentions that the user hasn't seen before in some special way. <code>firstTime</code> also indicates to your application whether or not the area in which your application is to draw has been erased. If <code>firstTime</code> is <code>false</code> , the area is not guaranteed to be blank; your application will need to erase it.
<code>flags</code>	The global user preferences for this attention attempt combined with the custom flags passed in by the developer. Only the lower 16 bits of this field have meaning; use <code>kAttnFlagsSoundBit</code> , <code>kAttnFlagsLEDBit</code> , <code>kCustomFlagsVibrateBit</code> , and <code>kAttnFlagsCustomEffectBit</code> (described under " <a href="#">AttnFlagsType</a> " on page 111) to interpret the contents of this field.

### drawList

When `kAttnCommandDrawList` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, the application needs to draw the appropriate list item in the attention dialog. The `drawList` structure accompanies the `kAttnCommandDrawList` command, and provides the information needed to draw the contents of that dialog.

```
struct AttnCommandArgsDrawListTag {
    RectangleType bounds;
    Boolean firstTime;
    AttnFlagsType flags;
};
```

## Attention Manager

### Attention Manager Data Structures

---

```
        Boolean selected;  
    } drawList;
```

#### Field Descriptions

<code>bounds</code>	Contains the window-relative bounding box for the area to draw. The clipping region is also set to the dimensions of this box to prevent accidental drawing outside.
<code>firstTime</code>	Set to <code>true</code> if the user has not yet seen this item. The value of this field could be used, for example, to trigger a custom sound the first time this attention item is presented to the user.
<code>flags</code>	The global user preferences for this attention attempt combined with the custom flags passed in by the developer. Only the lower 16 bits of this field have meaning; use <code>kAttnFlagsSoundBit</code> , <code>kAttnFlagsLEDBit</code> , <code>kCustomFlagsVibrateBit</code> , and <code>kAttnFlagsCustomEffectBit</code> (described under “ <a href="#">AttnFlagsType</a> ” on page 111) to interpret the contents of this field.
<code>selected</code>	Set to <code>true</code> if the item has been selected. It is up to your code to draw the item appropriately (typically by changing the UI colors) based upon the value of this flag.

#### **gotIt**

When `kAttnCommandGotIt` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, it is accompanied by an `gotIt` structure. This structure indicates whether the `kAttnCommandGotIt` command was generated because the user dismissed the attention, or whether the system is simply informing your application that [AttnForgetIt](#) was called. Your application normally ignores the latter case if your application made the call to `AttnForgetIt`.

```
struct AttnCommandArgsGotItTag {
    Boolean dismissedByUser;
} gotIt;
```

### Field Descriptions

`dismissedByUser`      `true` indicates that the user dismissed the attention. `false` indicates that the `kAttnCommandGotIt` command was generated by a call to [AttnForgetIt](#).

### iterate

When `kAttnCommandIterate` is passed to the application, either via the callback function or as a parameter accompanying the [sysAppLaunchCmdAttention](#) launch code, it is accompanied by an `iterate` structure. This structure contains any necessary data that the application may need in order to process the callback or launch code.

```
struct AttnCommandArgsIterateTag {
    UInt32 iterationData;
} iterate;
```

### Field Descriptions

`iterationData`      Any necessary data that the application may need in order to process the callback or launch code. The value of this field is that which was originally passed to [AttnIterate](#).

## AttnFlagsType

Pass a value of this type to [AttnGetAttention](#) and [AttnUpdate](#) to specify what means the device should or should not use to get the user's attention. A value of this type is also passed back to your code either as a parameter to the callback function or, if no callback was specified, as part of the structure passed with the [sysAppLaunchCmdAttention](#) launch code.

## Attention Manager

### Attention Manager Data Structures

---

```
typedef UInt32 AttnFlagsType;
```

Note that more bits may be defined if necessary to accommodate additional hardware.

---

Constant	Value	Description
kAttnFlagsSoundBit	0x0001	Plays a sound.
kAttnFlagsLEDBit	0x0002	Blinks an LED, if the device is so equipped.
kAttnFlagsVibrateBit	0x0004	Triggers vibration, if the device is so equipped.
kAttnFlagsCustomEffectBit	0x0008	Triggers an application-specific custom effect.
kAttnFlagsAllBits	0xFFFF	Uses all available means to get the user's attention.
kAttnFlagsUseUserSettings	0x0000	System-wide preferences determine what means are used to get the user's attention.

---

The following constant values can be used to override the user's settings and force or prevent specific behaviors:

---

Constant	Value	Description
kAttnFlagsAlwaysSound	kAttnFlagsSoundBit	Play a sound, regardless of the user's settings.
kAttnFlagsAlwaysLED	kAttnFlagsLEDBit	Blink an LED, if the device is so equipped, regardless of the user's settings.
kAttnFlagsAlwaysVibrate	kAttnFlagsVibrateBit	Vibrate, if the device is so equipped, regardless of the user's settings.
kAttnFlagsAlwaysCustomEffect	kAttnFlagsCustomEffectBit	Trigger an application-specific custom effect.

---

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>kAttnFlagsEverything</code>	<code>kAttnFlagsAllBits</code>	Use every available means to get the user's attention, regardless of the user's settings.
<code>kAttnFlagsNoSound</code>	<code>kAttnFlagsSoundBit &lt;&lt; 16</code>	Prevent a sound from being played, regardless of the user's settings.
<code>kAttnFlagsNoLED</code>	<code>kAttnFlagsLEDBit &lt;&lt; 16</code>	Prevent the LED from flashing, regardless of the user's settings.
<code>kAttnFlagsNoVibrate</code>	<code>kAttnFlagsVibrateBit &lt;&lt; 16</code>	Prevent vibration, regardless of the user's settings.
<code>kAttnFlagsNoCustomEffect</code>	<code>kAttnFlagsCustomEffectBit &lt;&lt; 16</code>	Prevent triggering of the application-specific custom effect.
<code>kAttnFlagsNothing</code>	<code>kAttnFlagsAllBits &lt;&lt; 16</code>	Disable all attention-getting mechanisms, regardless of the user's settings.

---

These constants can be used in combination. For example, to disable both sound and the LED, use `kAttnFlagsNoSound | kAttnFlagsNoLED`.

If neither `kAttnFlagsAlwaysSound` nor `kAttnFlagsNoSound` is set for a given attention item, a sound plays if and only if the user's preference is to play a sound and the user's preference for alarm volume is non-zero.

## **AttnLaunchCodeArgsType**

If a callback function is not specified in a call to [AttnGetAttention](#) and the Attention Manager needs your code to draw the details of your attention in the attention dialog or perform another attention-specific function, it sends a

## Attention Manager

### Attention Manager Data Structures

---

[sysAppLaunchCmdAttention](#) launch code to your application. Along with the launch code, it passes a pointer to the following structure, which indicates both what your code is expected to do and identifies the attention that triggered the launch code:

```
typedef struct {
    AttnCommandType command;
    UInt32 userData;
    AttnCommandArgsType *commandArgsP;
} AttnLaunchCodeArgsType;
```

#### Field Descriptions

command	Indicates what your code is being requested to do. The complete list of possible commands are described in the definition of <a href="#">AttnCommandType</a> .
userData	Identifier that distinguishes the particular attention item from others made by this application. This identifier was specified when the attention item was created.
commandArgsP	Pointer to command-specific arguments. See the description of each command for a discussion of that command's arguments.

When processing the launch code be aware that your application doesn't have application globals available to it; it is important that anything necessary to draw or otherwise display be available through `commandArgsP`.

#### AttnLevelType

Attention attempts can either be insistent or subtle. Insistent attention attempts make a serious effort to get the user's attention, by both displaying a dialog and possibly by triggering one or more special effects, such as blinking a light, vibrating, or playing a sound. Other alerts are of a less serious nature and shouldn't disrupt the user. Consequently, subtle attention attempts typically make the attention indicator blink and may trigger one or more special effects, but don't display the Attention Manager dialog. The user can then work until a suitable time, at which point they can tap

on the indicator to see what needs their attention. Subtle attention attempts might be used for telling the user that they have new e-mail, or perhaps that a holiday or birthday is coming up.

```
typedef UInt16 AttnLevelType;
```

The following table lists the two defined values for `AttnLevelType`:

Constant	Description
<code>kAttnLevelInsistent</code>	An insistent attention attempt. Make a serious effort to get the user's attention by displaying a dialog and optionally triggering one or more special effects.
<code>kAttnLevelSubtle</code>	A subtle attention attempt. Notify the user using special effects, but don't disrupt the user with the dialog if the device is in use.

Note that user preferences for the various special effects can't be set separately for subtle and insistent attention attempts. If your application needs to vary the effects based upon the `AttnLevelType`, pass a suitable value for the `flags` parameter in your [AttnGetAttention](#) call.

## Attention Manager Constants

In addition to the constant values defined specifically for use with [AttnCommandType](#), [AttnFlagsType](#), and [AttnLevelType](#), the Attention Manager defines the following constant types:

- [Error Code Constants](#)
- [Attention Manager Drawing Constants](#)
- [Attention Manager Feature Constants](#)

### Error Code Constants

The Attention Manager returns the following error code under the circumstances described below.

## Attention Manager

### Attention Manager Constants

---

Constant	Description
<code>attnErrMemory</code>	Returned by <a href="#">AttnGetAttention</a> when there is insufficient memory to perform the requested operation.

---

### Attention Manager Drawing Constants

The following four constants define the on-screen boundaries of the attention indicator:

Constant	Value	Description
<code>kAttnIndicatorLeft</code>	0	The left-hand edge of the attention indicator.
<code>kAttnIndicatorTop</code>	0	The top-most edge of the attention indicator.
<code>kAttnIndicatorWidth</code>	16	The width of the attention indicator.
<code>kAttnIndicatorHeight</code>	16	The height of the attention indicator.

---

The following two constants are used when drawing the list view. Applications should use these constants to format the display of information in the Attention Manager's list view. Draw the application's small icon centered within the first `kAttnListMaxIconWidth` pixels of the drawing bounds. Then draw two lines of text describing the attention, left-justified, starting at `kAttnListTextOffset` from the left edge of the drawing bounds.

Constant	Value	Description
<code>kAttnListMaxIconWidth</code>	15	Maximum width of the application's icon. If the icon is narrower than this, it should be drawn centered within this width.
<code>kAttnListTextOffset</code>	17	Offset, from the left-hand edge of the drawing bounds, of the textual description of the attention.

---

## Attention Manager Feature Constants

The Attention Manager defines a read-only feature ('attn', 0) that indicates the current user settings and capabilities of the hardware. The upper 16 bits of the feature indicate whether or not the hardware has the capability to perform that sort of alert. The lower 16 bits indicate whether the user has currently enabled that sort of alert.

---

<b>Constant</b>	<b>Value</b>	<b>Description</b>
kAttnFtrCreator	'attn'	Attention Manager feature creator.
kAttnFtrCapabilities	0	Attention Manager feature number.

---

When working with the value obtained with `FtrGet`, use the following two constants to separate those bits that contain the user settings from those bits that identify the device's capabilities:

---

<b>Constant</b>	<b>Value</b>	<b>Description</b>
kAttnFlagsUserSettingsMask	kAttnFlagsAllBits	Mask to isolate those bits that contain the user settings.
kAttnFlagsCapabilitiesMask	kAttnFlagsAllBits << 16	Mask to isolate those bits that contain the device capabilities.

---

These constants can be used to interpret the device capabilities (`kAttnFlagsHas...`) and the user settings (`kAttnFlagsUserWants...`):

## Attention Manager

### Attention Manager Constants

---

Constant	Value	Description
kAttnFlagsHasLED	kAttnFlagsLEDBit << 16	The device has an LED that can be illuminated to indicate an alert.
kAttnFlagsHasSound	kAttnFlagsSoundBit << 16	The device is capable of playing a sound to indicate an alert.
kAttnFlagsHasVibrate	kAttnFlagsVibrateBit << 16	The device is capable of vibrating to indicate an alert.
kAttnFlagsHasCustomEffect	kAttnFlagsCustomEffectBit << 16	Not used.
kAttnFlagsUserWantsLED	kAttnFlagsLEDBit	The user wants the LED illuminated to signal an alert.
kAttnFlagsUserWantsSound	kAttnFlagsSoundBit	The user wants a sound played to signal an alert.
kAttnFlagsUserWantsVibrate	kAttnFlagsVibrateBit	The user wants the device to vibrate to signal an alert.
kAttnFlagsUserWantsCustomEffect	kAttnFlagsCustomEffectBit	Not used.

---

## Attention Manager Functions

### AttnDoSpecialEffects

<b>Purpose</b>	Triggers an Attention Manager special effect set.
<b>Declared In</b>	<code>AttentionMgr.h</code>
<b>Prototype</b>	<code>Err AttnDoSpecialEffects (AttnFlagsType flags)</code>
<b>Parameters</b>	<code>-&gt; flags</code> Specifies the behavior to be exhibited by this special effects request. See <a href="#">AttnFlagsType</a> for the various bits that make up this flag. Note that the behavior is undefined if you set incompatible flags. Supply <code>kAttnFlagsUseUserSettings</code> to have this attention request follow the user's pre-set preferences.
<b>Result</b>	Returns <code>errNone</code> if no problems were encountered. Returns <code>attnErrMemory</code> if there wasn't enough memory to accommodate the attention request.
<b>Comments</b>	This routine is provided as a convenience for applications that need to trigger special effects. It does the equivalent of one "nag" of an Attention Manager special effect set.
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.

## Attention Manager

### Attention Manager Functions

---

## AttnForgetIt

- Purpose** Provides a way for applications to tell the Attention Manager to forget about an attention item.
- Declared In** `AttentionMgr.h`
- Prototype** `Boolean AttnForgetIt (UInt16 cardNo, LocalID dbID, UInt32 userData)`
- Parameters**
- > `cardNo` Card number on which the application making the request resides.
  - > `dbID` Database ID of the application making the request.
  - > `userData` Identifier that distinguishes the attention attempt from others made by the same application. This identifier can be an integer, a pointer, or any other 32-bit value.
- Result** Returns `true` if the item was removed, `false` if a matching item was not found.
- Comments** You typically call this function after your application has handled a “Go There” event and the user has read about the item. For example, if there is a subtle attention pending that says “you have three e-mail messages waiting” and you go to the e-mail application on your own and read your e-mail, the subtle notification must disappear. `AttnForgetIt` allows the application to do this.
- Note that this call can be made when the Attention Manager dialog is on-screen (though presumably that is rare, since the application is probably not doing much at this point). If this call removes a list item, then the Attention Manager may call back into other items to redraw the list.
- If this call removes the last item when any indicator is present, the indicator disappears. If this call removes the last unread item, but read items remain, the indicator switches from blinking to steady state.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## **AttnGetAttention**

**Purpose**            Requests the user's attention.

**Declared In**      `AttentionMgr.h`

**Prototype**        `Err AttnGetAttention (UInt16 cardNo,  
                         LocalID dbID, UInt32 userData,  
                         AttnCallbackProc *callbackFnP,  
                         AttnLevelType level, AttnFlagsType flags,  
                         UInt16 nagRateInSeconds, UInt16 nagRepeatLimit)`

**Parameters**

- > `cardNo`            Card number on which the application making the request resides.
- > `dbID`                Database ID of the application making the request.
- > `userData`           Application-specific data that is later passed back to your code through the callback function. If no callback function is specified in the `callbackFnP` parameter, this data is included in what is passed along with a [sysAppLaunchCmdAttention](#) launch code. `userData` can be an integer, a pointer, or any other 32-bit value as needed by your application. Most applications pass the unique ID or other key for the record which caused the attention request. `userData` is also used to distinguish a given attention attempt from others made by the same application.

## Attention Manager

### Attention Manager Functions

---

- > `callbackFnP`  
Pointer to the function registered by the application to be called by the Attention Manager when the attention is displayed or removed. See [AttnCallbackProc](#), below, for the callback function's parameters. Supply `NULL` to instead have a [sysAppLaunchCmdAttention](#) launch code sent to the application that made the attention request whenever the attention is displayed or removed.
- > `level`  
Indicates the annoyance level. Pass one of the values defined for [AttnLevelType](#).
- > `flags`  
Behavior override, if necessary, for this attention request. This override allows, for instance, silent alarms or noisy alarms. See [AttnFlagsType](#) for the various bits that make up this flag. Note that the behavior is undefined if you set incompatible flags. Supply `kAttnFlagsUseUserSettings` to have this attention request follow the user's pre-set preferences.
- > `nagRateInSeconds`  
How long to wait before nagging.
- > `nagRepeatLimit`  
How many times to nag, excluding the first attempt.

**Result** Returns `errNone` if no problems were encountered. Returns `attnErrMemory` if there wasn't enough memory to accommodate the attention request.

**Comments** The combination of `cardNo`, `dbID` and `userData` uniquely identify an attention-getting attempt. If another call is made to `AttnGetAttention` with identical values for these arguments, an error is reported. To update or delete an existing attention item, pass these same values to [AttnUpdate](#) or [AttnForgetIt](#), respectively.

In response to `AttnGetAttention`, the behavior of the operating system or application depends on whether there already are other demands and on the annoyance level passed in the `AttnGetAttention` call.

- No other demands, insistent attention request:

The Attention Manager puts up a dialog that details the current attempt to get the user's attention.

- Other demands exist, insistent attention request:

The Attention Manager adds a summary of the current attempt to get the user's attention to a list of things that need attention. If the dialog is currently in detail form—which is the case if just one other demand exists—the view is refreshed, changing from detail to list form. In this case, the pen and key event queues are also flushed so that any user events that are happening while the display is changing are explicitly ignored. Two exceptions to this behavior exist: if all existing attentions are subtle, or if all existing insistent attentions were snoozed, the new insistent attention brings up the dialog in detail mode, rather than list mode.

- Subtle attention request:

The Attention Manager starts the attention indicator blinking, and adds the item to its list for later display, unless the dialog is currently being displayed in list mode. In this event, the new subtle attention item simply appears in the list; the indicator does not blink to announce it.

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

**See Also**    [AttnUpdate](#)

## Attention Manager

### Attention Manager Functions

---

## AttnGetCounts

<b>Purpose</b>	Returns the number of attention items that are currently pending.								
<b>Declared In</b>	AttentionMgr.h								
<b>Prototype</b>	<pre>UInt16 AttnGetCounts (UInt16 cardNo, LocalID dbID, UInt16 *insistentCountP, UInt16 *subtleCountP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; cardNo</td><td>If this value is zero, counts pending attention items from applications on all cards. Otherwise, counts only pending attention items from applications on the specified card.</td></tr><tr><td>-&gt; dbID</td><td>If this value is zero, counts pending attention items from all applications. Otherwise, counts only pending attention items from applications with the specified database ID.</td></tr><tr><td>&lt;- insistentCountP</td><td>Pointer to a 16-bit unsigned value that is filled in with the number of insistent items pending. Pass NULL for this parameter if you don't need to know the number of insistent items that are pending.</td></tr><tr><td>&lt;- subtleCountP</td><td>Pointer to a 16-bit unsigned value that is filled in with the number of subtle items pending. Pass NULL for this parameter if you don't need to know the number of subtle items that are pending.</td></tr></table>	-> cardNo	If this value is zero, counts pending attention items from applications on all cards. Otherwise, counts only pending attention items from applications on the specified card.	-> dbID	If this value is zero, counts pending attention items from all applications. Otherwise, counts only pending attention items from applications with the specified database ID.	<- insistentCountP	Pointer to a 16-bit unsigned value that is filled in with the number of insistent items pending. Pass NULL for this parameter if you don't need to know the number of insistent items that are pending.	<- subtleCountP	Pointer to a 16-bit unsigned value that is filled in with the number of subtle items pending. Pass NULL for this parameter if you don't need to know the number of subtle items that are pending.
-> cardNo	If this value is zero, counts pending attention items from applications on all cards. Otherwise, counts only pending attention items from applications on the specified card.								
-> dbID	If this value is zero, counts pending attention items from all applications. Otherwise, counts only pending attention items from applications with the specified database ID.								
<- insistentCountP	Pointer to a 16-bit unsigned value that is filled in with the number of insistent items pending. Pass NULL for this parameter if you don't need to know the number of insistent items that are pending.								
<- subtleCountP	Pointer to a 16-bit unsigned value that is filled in with the number of subtle items pending. Pass NULL for this parameter if you don't need to know the number of subtle items that are pending.								
<b>Result</b>	Returns the total number of items, both insistent and subtle, that are currently pending.								
<b>Comments</b>	Call this function if you need to exhibit different behavior if attention items are already pending.								
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.								

## **AttnIndicatorEnable**

<b>Purpose</b>	Enables and disables the on-screen attention indicator.
<b>Declared In</b>	<code>AttentionMgr.h</code>
<b>Prototype</b>	<code>void AttnIndicatorEnable (Boolean enableIt)</code>
<b>Parameters</b>	-> <code>enableIt</code> <code>true</code> to enable the attention indicator, <code>false</code> to disable it.
<b>Result</b>	Returns nothing.
<b>Comments</b>	<p>This function is used by applications to enable or disable the on-screen attention indicator. The indicator only blinks when all of the following are true:</p> <ul style="list-style-type: none"><li>• The indicator is enabled.</li><li>• The indicator is being asked to blink by the attention manager.</li><li>• The operating system isn't using the display in such a way as to prevent the attention indicator from showing, such as when the menu bar is being displayed or when a modal dialog is on top of the form.</li></ul> <p>The attention indicator is enabled by default. If your application controls the upper portion of the screen and needs to prevent the attention indicator from being displayed, call <a href="#">AttnIndicatorEnable</a> and pass it a value of <code>false</code>.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">AttnIndicatorEnabled</a>

## Attention Manager

### Attention Manager Functions

---

#### AttnIndicatorEnabled

- Purpose** Returns whether the on-screen attention indicator is currently enabled.
- Declared In** `AttentionMgr.h`
- Prototype** `Boolean AttnIndicatorEnabled (void)`
- Parameters** None.
- Result** Returns `true` if the on-screen attention indicator is currently enabled, `false` otherwise.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [AttnIndicatorEnable](#)

#### AttnIterate

- Purpose** Instructs the Attention Manager to check each attention item currently pending and, for those that match the specified card number and database ID, invoke the item's callback routine. If a callback routine was not specified in the request, the [sysAppLaunchCmdAttention](#) launch code is sent to the application that made the attention request.
- Declared In** `AttentionMgr.h`
- Prototype** `void AttnIterate (UInt16 cardNo, LocalID dbID, UInt32 iterationData)`
- Parameters**
- |                        |   |
|------------------------|---|
| -> <code>cardNo</code> | Card number on which the application that made the request resides. |
| -> <code>dbID</code>   | Database ID of the application that made the request.               |

-> iterationData

Any necessary data that the application may need in order to process the callback or launch code. See the description of the [AttnCallbackProc](#) function for more information on this parameter.

**Result** Returns nothing.

**Comments** This function iterates through all of the attention requests made by this application and uses the callback or launch code for each to inform the application about the attention request. When an application receives a [sysAppLaunchCmdSyncNotify](#) launch code, signifying that a HotSync occurred that affected that application's databases, the application typically calls `AttnIterate` so it can remove attention requests for records that may have been removed during the HotSync. Applications can also call [AttnGetAttention](#) after a HotSync, if necessary.

Note that you can call [AttnForgetIt](#) inside the iteration since it only marks the record for deletion and thus doesn't confuse the iteration.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## AttnListOpen

**Purpose** Displays the attention dialog in list mode and, after the user has dismissed it, acts accordingly based on how it was dismissed.

**Declared In** `AttentionMgr.h`

**Prototype** `void AttnListOpen (void)`

**Parameters** None.

**Result** Returns nothing.

## Attention Manager

### Attention Manager Functions

---

- Comments** This function allows applications that do not provide the blinking attention indicator to open the list, if necessary.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## AttnUpdate

- Purpose** Updates one or more aspects of a specified attention item.
- Declared In** `AttentionMgr.h`
- Prototype** `Boolean AttnUpdate (UInt16 cardNo, LocalID dbID, UInt32 userData, AttnCallbackProc *callbackFnP, AttnFlagsType *flagsP, UInt16 *nagRateInSecondsP, UInt16 *nagRepeatLimitP)`
- Parameters**
- > `cardNo` Card number on which the application that made the request resides.
  - > `dbID` Database ID of the application that made the request.
  - > `userData` Application-specific data that is passed back to your code through the callback function. If no callback function is specified in the `callbackFnP` parameter, this data is included in what is passed along with a [sysAppLaunchCmdAttention](#) launch code. `userData` can be an integer, a pointer, or any other 32-bit value. Most applications pass the unique ID or other key for the record which caused the attention request. The value of the `userData` parameter is also used to distinguish a given attention attempt from others made by the same application.

-> `callbackFnP`

Registers a new function to be called by the Attention Manager when the attention is displayed or removed. The function to which this parameter points should conform to [AttnCallbackProc](#). Supply `NULL` to instead have a [sysAppLaunchCmdAttention](#) launch code sent to the application that made the attention request whenever the attention is displayed or removed.

---

**IMPORTANT:** Because `NULL` indicates that a launch code should be sent whenever the callback would otherwise be invoked, it isn't used in this instance to leave the original setting for the `callbackFnP` parameter intact. The value supplied for this parameter *always* overwrites the value supplied in the original attention request.

---

-> `flagsP`

Pointer to a set of flags that can be used to override user-specified attention behavior; for instance, to force silent or noisy alarms. See [AttnFlagsType](#) for the various bits that make up this flag, and note that the behavior is undefined if you set incompatible flags. Pass `NULL` to leave the current flag settings unchanged.

-> `nagRateInSecondsP`

Pointer to the length of time to wait before nagging. Pass `NULL` to leave the "nag rate" unchanged.

-> `nagRepeatLimitP`

Pointer to the maximum number of times the user should be nagged. Pass `NULL` to leave the nag repeat limit unchanged.

**Result** Returns `true` if the update was successful, `false` if no matching attention item was found.

## Attention Manager

### *Application-Defined Functions*

---

**Comments** This call may result in the callback function being called to re-display the item. If no callback function is specified, the [sysAppLaunchCmdAttention](#) launch code is instead sent to your application. It may also result in callbacks to other pending attention requests.

You call `AttnUpdate` to tell the Attention Manager to update, forcing it to call into all of its clients to redraw. This provides a way for an application to update the text of an attention item without tearing down and re-opening the Attention Manager dialog. For example, `AttnUpdate` could be used to update an existing email notification to say “You have three new email messages” when additional messages are received.

Although `AttnUpdate` may cause a given attention item to redraw, it does not rerun the special effects (if any) that occurred when that attention item was added. If you want to trigger Attention Manager effects for a particular item, call [AttnForgetIt](#) followed by [AttnGetAttention](#).

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [AttnGetAttention](#)

## Application-Defined Functions

### **AttnCallbackProc**

**Purpose** Provides a function prototype to be used by callback functions supplied to [AttnGetAttention](#) and [AttnUpdate](#). The supplied

function is invoked by the Attention Manager whenever the attention is displayed or removed.

**Declared In**    `AttentionMgr.h`

**Prototype**    `typedef Err AttnCallbackProc  
                  (AttnCommandType command, UInt32 userData,  
                  AttnCommandArgsType *commandArgsP)`

**Parameters**

<code>-&gt; command</code>	Indicates what the callback function is being requested to do. The complete list of possible commands are described in the definition of <a href="#">AttnCommandType</a> .
<code>-&gt; userData</code>	Identifier that distinguishes the particular attention item from others made by this application. This identifier was specified when the attention item was created.
<code>-&gt; commandArgsP</code>	Pointer to command-specific arguments. See the description of each command for a discussion of that command's arguments.

**Result**    The callback function should return `errNone` if it correctly handled the command, or an appropriate error code otherwise. If the callback function returns an error code other than `errNone`, the attention is removed from the list of active attention items.

**Comments**    For a given attention item, the Attention Manager calls back to the code resource that created that item whenever the Attention Manager needs the resource to draw the attention dialog contents or whenever it needs to inform the code resource of activity relating to the attention item. The Attention Manager calls back using one of two mechanisms:

- If a callback routine has been specified for a given attention item, the Attention Manager invokes the specified routine. This callback routine doesn't have application globals available to it, so it is important that anything necessary to draw or otherwise display be available through

## Attention Manager

### *Application-Defined Functions*

---

commandArgsP. A callback routine is typically used by libraries and system extensions.

- If a callback routine has not been specified for a given attention item, the Attention Manager instead sends a [sysAppLaunchCmdAttention](#) launch code to the application that registered the attention item. Accompanying that launch code is an [AttnLaunchCodeArgsType](#) structure containing the three parameters documented above. Applications typically use the launch-code mechanism due to the restrictions that are placed on callback routines.

---

**IMPORTANT:** It is your responsibility to ensure that the callback procedure is still in the same place when it gets called, dealing with the possibility that the code resource might be unlocked and moved in memory, and with the possibility that the database containing the code resource might be deleted. For the most part, these problems don't exist when using launch codes.

---

**Compatibility** Invoked only if [4.0 New Feature Set](#) is present.

# Categories

---

This chapter describes the category API as declared in the header file `Category.h`. It discusses the following topics:

- [Category Data Structures](#)
- [Category Constants](#)
- [Category Functions](#)

For more information on categories, see the section “[Categories](#)” on page 116 in the *Palm OS Programmer’s Companion*, vol. I.

## Category Data Structures

### AppInfoPtr

The `AppInfoPtr` defines a pointer to an [AppInfoType](#) structure.

```
typedef AppInfoType *AppInfoPtr;
```

### AppInfoType

The `AppInfoType` structure shown below maps category names to category indexes and unique IDs. To use the category API described in this chapter, a database’s application info block must either be an `AppInfoType` structure, or it must have an `AppInfoType` structure as its first field.

```
typedef struct {
    UInt16    renamedCategories;
    Char      categoryLabels [dmRecNumCategories]
                [dmCategoryLength];
    UInt8     categoryUniqIDs [dmRecNumCategories];
    UInt8     lastUniqID;
    UInt8     padding;
} AppInfoType;
```

## Categories

### Category Constants

---

Allocate the application info block in the storage heap and use the [DmSetDatabaseInfo](#) function to set the database's application info ID to the local ID of this structure. Then, use the [CategoryInitialize](#) function to initialize it with a localized list of strings containing the category names.

#### Field Descriptions

<code>renamedCategories</code>	Used by <a href="#">CategorySetName</a> as a bit field indicating which categories have been renamed. Usually cleared by a conduit.
<code>categoryLabels</code>	An array of strings containing the category names. The maximum size of the array is <code>dmRecNumCategories</code> , and the maximum length of each string in the array is <code>dmCategoryLength</code> . Both of these constants are defined in <code>DataMgr.h</code> .
<code>categoryUniqIDs</code>	Category IDs used for synchronization with the desktop database. Unique IDs generated by the device are between 0 and 127. Unique IDs generated by the desktop computer are between 128 and 255.
<code>lastUniqID</code>	Used for sorting and assigning unique IDs.

## Category Constants

The following category constants are defined:

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>categoryHideEditCategory</code>	10000	Used to suppress the “Edit Categories” item.
<code>categoryDefaultEditCategoryString</code>	10001	Used to show the default “Edit Categories” item.

---

---

**NOTE:** These constants look like system resource IDs, but they are not. To use a non-default string for the “Edit Categories” item you pass a resource ID of a string containing your title. If you want to use the default or hide the item, you pass one of these constants. They are within the system resource ID range (that is, they are greater than 10000) so that they don’t conflict with any other possible value for that parameter.

---

**Compatibility** Both `categoryHideEditCategory` and `categoryDefaultEditCategoryString` are defined only if the [3.5 New Feature Set](#) is present.

## Category Functions

### CategoryCreateList

<b>Purpose</b>	Populate a popup list with a database's categories.												
<b>Declared In</b>	Category.h												
<b>Prototype</b>	<pre>void CategoryCreateList (DmOpenRef db, ListType *listP, UInt16 currentCategory, Boolean showAll, Boolean showUneditables, UInt8 numUneditableCategories, UInt32 editingStrID, Boolean resizeList)</pre>												
<b>Parameters</b>	<table><tr><td>-&gt; db</td><td>Open database containing the category information you want to read.</td></tr><tr><td>&lt;- listP</td><td>Pointer to the <a href="#">ListType</a> structure that should display the categories.</td></tr><tr><td>-&gt; currentCategory</td><td>Index of the category to select. The index is the index into the categoryLabels array. The default is to have the "Unfiled" category selected.</td></tr><tr><td>-&gt; showAll</td><td>true to include an "All" list item.</td></tr><tr><td>-&gt; showUneditables</td><td>true to show uneditable categories.</td></tr><tr><td>-&gt; numUneditableCategories</td><td>The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the categoryLabels array. For example, it's common to have an "Unfiled" category at position zero that is not editable. This function displays the uneditable categories at the end of the popup list.</td></tr></table>	-> db	Open database containing the category information you want to read.	<- listP	Pointer to the <a href="#">ListType</a> structure that should display the categories.	-> currentCategory	Index of the category to select. The index is the index into the categoryLabels array. The default is to have the "Unfiled" category selected.	-> showAll	true to include an "All" list item.	-> showUneditables	true to show uneditable categories.	-> numUneditableCategories	The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the categoryLabels array. For example, it's common to have an "Unfiled" category at position zero that is not editable. This function displays the uneditable categories at the end of the popup list.
-> db	Open database containing the category information you want to read.												
<- listP	Pointer to the <a href="#">ListType</a> structure that should display the categories.												
-> currentCategory	Index of the category to select. The index is the index into the categoryLabels array. The default is to have the "Unfiled" category selected.												
-> showAll	true to include an "All" list item.												
-> showUneditables	true to show uneditable categories.												
-> numUneditableCategories	The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the categoryLabels array. For example, it's common to have an "Unfiled" category at position zero that is not editable. This function displays the uneditable categories at the end of the popup list.												

- > `editingStrID` The resource ID of a `tSTR` resource to use as the Edit Categories list item. To use the default string (“Edit Categories”) pass the constant `categoryDefaultEditCategoryString`.  
If you don’t want users to edit categories, pass the `categoryHideEditCategory` constant.
- > `resizeList` `true` to resize the list to the number of categories. Set to `true` for popups, `false` otherwise.

**Result** Returns nothing.

**Comments** The “All” item is first in the list (if the `showAll` parameter is `true`), followed by the editable categories in the database and then the categories that cannot be edited. The option to edit categories is last in the list and can be suppressed if desired.

You rarely call this function directly. Instead, most applications use [CategorySelect](#), which calls this function and fully manages the user’s selection of a category in the popup list. Use `CategoryCreateList` only if you want more control over the category popup list.

This function obtains the `db` parameter’s `appInfoID`, reads the [AppInfoType](#) structure at that location, and uses the information in it to initialize the `listP`’s `items` array with the names of the database’s categories. You must have already allocated the structure pointed to by `listP`. `CategoryCreateList` does not display the list; use [LstPopupMenu](#) or [LstDrawList](#) to do so.

You must balance a call to `CategoryCreateList` with a call to [CategoryFreeList](#). The `CategoryCreateList` function locks the resources for the category names. It also allocates the `listP` `items` array. `CategoryFreeList` unlocks all resources locked by `CategoryCreateList` and frees all memory allocated by `CategoryCreateList`.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

The constants `categoryDefaultEditCategoryString` and `categoryHideEditCategory` are defined only if [3.5 New](#)

[Feature Set](#) is present. In earlier versions, you can suppress the Edit Categories string by passing 0 for the `editingStrID` parameter, or include the item by passing `categoryEditStrID`.

**See Also** [CategoryCreateListV10](#)

## CategoryCreateListV10

**Purpose** Read a database's categories and set the category list.

**Declared In** `Category.h`

**Prototype**

```
void CategoryCreateListV10 (DmOpenRef db,
ListType *lst, UInt16 currentCategory,
Boolean showAll)
```

**Parameters**

-> db	Open database containing the category information you want to read.
<- lst	Pointer to the <a href="#">ListType</a> that should display the categories.
-> currentCategory	Index of the category to select. The index is the index into the <code>categoryLabels</code> array. The default is to have the "Unfiled" category selected.
-> showAll	true to include an "All" list item.

**Result** Returns nothing.

**Compatibility** This function corresponds to the Palm OS® 1.0 version of [CategoryCreateList](#). It is obsolete.

## CategoryEdit

<b>Purpose</b>	Event handler for the Edit Categories dialog.								
<b>Declared In</b>	Category.h								
<b>Prototype</b>	<pre>Boolean CategoryEdit (DmOpenRef db, UInt16 *category, UInt32 titleStrID, UInt8 numUneditableCategories)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; db</td><td>Open database containing the categories to be edited.</td></tr><tr><td>&lt;- category</td><td>Upon return, the index of the last category selected before the dialog was closed.</td></tr><tr><td>-&gt; titleStrID</td><td>The resource ID of a tSTR resource to use as the dialog's title. To use the default string ("Edit Categories"), pass the constant <code>categoryDefaultEditCategoryString</code>.</td></tr><tr><td>-&gt; numUneditableCategories</td><td>The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the <code>categoryLabels</code> array. For example, it's common to have an "Unfiled" category at position zero that is not editable.</td></tr></table>	-> db	Open database containing the categories to be edited.	<- category	Upon return, the index of the last category selected before the dialog was closed.	-> titleStrID	The resource ID of a tSTR resource to use as the dialog's title. To use the default string ("Edit Categories"), pass the constant <code>categoryDefaultEditCategoryString</code> .	-> numUneditableCategories	The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the <code>categoryLabels</code> array. For example, it's common to have an "Unfiled" category at position zero that is not editable.
-> db	Open database containing the categories to be edited.								
<- category	Upon return, the index of the last category selected before the dialog was closed.								
-> titleStrID	The resource ID of a tSTR resource to use as the dialog's title. To use the default string ("Edit Categories"), pass the constant <code>categoryDefaultEditCategoryString</code> .								
-> numUneditableCategories	The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the <code>categoryLabels</code> array. For example, it's common to have an "Unfiled" category at position zero that is not editable.								
<b>Result</b>	Returns <code>true</code> if any of the following conditions are <code>true</code> : <ul style="list-style-type: none"><li>• The current category is renamed.</li><li>• The current category is deleted.</li><li>• The current category is merged with another category.</li></ul>								
<b>Comments</b>	<p>You rarely call this function directly. The <a href="#">CategorySelect</a> function calls it when the user chooses the Edit Category list item.</p> <p>This function both displays the Edit Categories dialog and handles the result of the user actions. It updates the <a href="#">AppInfoType</a> structure's list of categories and reassigns database records to new categories as needed. If a user deletes a category, <code>CategoryEdit</code></p>								

## Categories

### Category Functions

---

moves all of the records belonging to that category to the Unfiled category. If a category is renamed to be the same as an existing category, this function moves all of the old category's records to the new category.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [CategoryEditV20](#), [CategoryEditV10](#), [DmMoveCategory](#)

## CategoryEditV20

**Purpose** Event handler for the Edit Categories dialog.

**Declared In** `Category.h`

**Prototype** `Boolean CategoryEditV20 (DmOpenRef db, UInt16 *category, UInt32 titleStrID)`

**Parameters**

<code>-&gt; db</code>	Database containing the categories to be edited.
<code>&lt;- category</code>	Upon return, the last category selected before the dialog was closed.
<code>-&gt; titleStrID</code>	The resource ID of a tSTR resource to use as the dialog's title.

**Result** Returns `true` if any of the following conditions are `true`:

- The current category is renamed.
- The current category is deleted.
- The current category is merged with another category.

**Compatibility** This function corresponds to the Palm OS 2.0 version of `CategoryEdit`. Implemented only if [2.0 New Feature Set](#) is present. This function is obsolete.

**See Also** [CategoryEdit](#), [CategoryEditV10](#)

## CategoryEditV10

<b>Purpose</b>	Event handler for the Edit Categories dialog.
<b>Declared In</b>	Category.h
<b>Prototype</b>	Boolean CategoryEditV10 (DmOpenRef db, UInt16 *category)
<b>Parameters</b>	-> db                    Open database containing the categories to be edited.  <- category        Upon return, the last category selected before the dialog was closed.
<b>Result</b>	Returns true if any of the following conditions are true: <ul style="list-style-type: none"><li>• The current category is renamed.</li><li>• The current category is deleted.</li><li>• The current category is merged with another category.</li></ul>
<b>Compatibility</b>	This function corresponds to the Palm OS 1.0 version of CategoryEdit. It is obsolete.
<b>See Also</b>	<a href="#">CategoryEdit</a> , <a href="#">CategoryEditV20</a>

## CategoryFind

<b>Purpose</b>	Return the index of a category given its name.
<b>Declared In</b>	Category.h
<b>Prototype</b>	UInt16 CategoryFind (DmOpenRef db, const Char *name)
<b>Parameters</b>	-> db                    Open database to search.

## Categories

### Category Functions

---

-> name                      Category name. Pass the empty string to find the first unused category.

**Result**                      Returns the index of the category's entry in the `categoryLabels` array (see [AppInfoType](#)). Returns `dmAllCategories` if the category does not exist.

## CategoryFreeList

**Purpose**                      Unlock or free memory locked or allocated by [CategoryCreateList](#).

**Declared In**                `Category.h`

**Prototype**                 `void CategoryFreeList (DmOpenRef db,  
ListType *listP, Boolean showAll,  
UInt32 editingStrID)`

**Parameters**

- > db                            Open database containing the categories.
- > listP                        Pointer to the category list. (See [ListType](#).)
- > showAll                     true if the list was created with an "All" category.
- > editingStrID                The resource ID that you passed as the `editingStrID` parameter to [CategoryCreateList](#). This function unlocks the resource.

**Result**                      Returns nothing.

**Comments**                 You only need to call this function if you explicitly call [CategoryCreateList](#). Typical applications call `CategorySelect`, which handles both the creation and deletion of the list.

This function frees the items in the popup list `listP`'s `items` array and it unlocks other resources that `CategoryCreateList` may have locked.

This function does **not** remove the categories from the passed database, and it does **not** free the `ListType` structure pointed to by `listP`. (Typically, a list is freed when its form is freed.)

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [CategoryFreeListV10](#)

## CategoryFreeListV10

**Purpose** Unlock or free memory locked or allocated by [CategoryCreateListV10](#).

**Declared In** `Category.h`

**Prototype** `void CategoryFreeListV10 (DmOpenRef db,  
ListType *lst)`

**Parameters**

-> db	Open database containing the categories.
-> listP	Pointer to the category list. (See <a href="#">ListType</a> .)

**Result** Returns nothing.

**Compatibility** This function corresponds to the Palm OS 1.0 version of `CategoryFreeList`. It is obsolete.

**See Also** [CategoryFreeList](#)

## CategoryGetName

- Purpose** Return the name of the specified category.
- Declared In** `Category.h`
- Prototype**  
`void CategoryGetName (DmOpenRef db, UInt16 index, Char *name)`
- Parameters**
- |          |   |
|----------|---|
| -> db    | Database that contains the categories.  |
| -> index | Category index. This is the index into the <code>categoryLabels</code> array in the <a href="#">AppInfoType</a> structure. You can retrieve this index from a database record's attribute word. |
| <- name  | Buffer to hold category name. Buffer should be <code>dmCategoryLength</code> in size.   |
- Result** Stores the category name in the name buffer passed.  
May display a fatal error message if the index is out of range.
- Comments** You can use this function to find out the name of a given database record's category. Use the [DmRecordInfo](#) call to obtain the category index from the given record. For example:
- ```
DmOpenRef myDB;  
UInt16 record, attr, category;  
Char *name;  
  
DmRecordInfo(myDB, record, &attr, NULL, NULL);  
category = attr & dmRecAttrCategoryMask;  
CategoryGetName(myDB, category, name);
```
- The category's name is copied into the variable you pass for the name parameter.
- See Also** [CategorySetName](#)

## CategoryGetNext

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                          |          |                 |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------------------|----------|-----------------|
| <b>Purpose</b>       | Return the index of the next category after a given category.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |       |                                          |          |                 |
| <b>Declared In</b>   | Category.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |       |                                          |          |                 |
| <b>Prototype</b>     | <pre>UInt16 CategoryGetNext (DmOpenRef db,                         UInt16 index)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                       |       |                                          |          |                 |
| <b>Parameters</b>    | <table><tr><td>-&gt; db</td><td>Open database containing the categories.</td></tr><tr><td>-&gt; index</td><td>Category index.</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                              | -> db | Open database containing the categories. | -> index | Category index. |
| -> db                | Open database containing the categories.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |       |                                          |          |                 |
| -> index             | Category index.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |       |                                          |          |                 |
| <b>Result</b>        | Category index of next category.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |                                          |          |                 |
| <b>Comments</b>      | <p>The intended use of this function is to allow your users to cycle through categories. For example, the built-in applications cycle through categories when the user presses the corresponding hard-key button. (See the <code>ListViewNextCategory</code> function in the Address Book sample application for an example.) Note that categories are not displayed in the same order as they are stored.</p> <p>Do not use this function for searching for a particular category or iterating through a category list.</p> |       |                                          |          |                 |
| <b>Compatibility</b> | <p>In Palm OS 1.0, the system chose <code>Unfiled</code> as one category.</p> <p>In Palm OS 2.0 and later, the system skips both <code>Unfiled</code> and categories with empty records.</p>                                                                                                                                                                                                                                                                                                                                 |       |                                          |          |                 |

## CategoryInitialize

- Purpose** Initialize the category names, IDs, and flags.
- Declared In** `Category.h`
- Prototype**  
`void CategoryInitialize (AppInfoPtr appInfoP,  
UInt16 localizedAppInfoStrID)`
- Parameters**
- `->appInfoP` Pointer to the locked application info block. See [AppInfoType](#).
  - `->localizedAppInfoStrID` Resource ID of the localized category names. This must be a resource of the type `appInfoStringsRsc ('tAIS')`.
- Result** Returns nothing.
- Comments** Call this function at database creation time to initialize the database's categories from a list of localized strings.
- `CategoryInitialize` initializes the [AppInfoType](#) structure that is associated with your database. It does not create the structure. To create the structure, you must allocate it in the storage heap (using [DmNewHandle](#)) and associate it with your database using [DmSetDatabaseInfo](#).
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## CategorySelect

- Purpose** Process the selection and editing of categories.
- Declared In** `Category.h`
- Prototype**
- ```
Boolean CategorySelect (DmOpenRef db,  
const FormType *frm, UInt16 ctlID, UInt16 lstID,  
Boolean title, UInt16 *categoryP,  
Char *categoryName, UInt8 numUneditableCategories,  
UInt32 editingStrID)
```
- Parameters**
- > `db` Open database containing the categories.
  - > `frm` Form that contains the category popup list.
  - > `ctlID` ID of the popup trigger.
  - > `lstID` ID of the popup list.
  - > `title` `true` to have an "All" list item. (In general, if the trigger is in the form's title bar, it should have an "All" item. If the trigger is elsewhere in the form, it should not.)
  - <-> `categoryP` Index of the selected category. The index is the index into the `categoryLabels` array.
  - <-> `categoryName` Name of the selected category.
  - > `numUneditableCategories` The number of categories that the user cannot edit. You should store uneditable categories at the beginning of the `categoryLabels` array. For example, it's common to have an "Unfiled" category at position zero that is not editable. This function displays the uneditable categories at the end of the popup list.
  - > `editingStrID` The resource ID of a `tSTR` resource to use as the Edit Categories list item. To use the default string ("Edit Categories"), pass the constant `categoryDefaultEditCategoryString`.

## Categories

### Category Functions

---

If you don't want users to edit categories, pass the `categoryHideEditCategory` constant.

**Result** Returns `true` if any of the following conditions are true:

- The current category is renamed.
- The current category is deleted.
- The current category is merged with another category.

**Comments** Call this function when the user taps the category popup trigger. This function handles all aspects of displaying the popup list and managing the user selection—It creates the popup list using [CategoryCreateList](#), displays the popup list, calls [CategoryEdit](#) if the user selects the Edit Categories item, uses [CategorySetTriggerLabel](#) to set the trigger label to the item the user selected, and then calls [CategoryFreeList](#) to free the list items array. Your application is responsible for checking the value of `categoryP` upon return and updating the display or changing the record's category to the new selection.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

The constants `categoryDefaultEditCategoryString` and `categoryHideEditCategory` are defined only if [3.5 New Feature Set](#) is present. In earlier versions, you can suppress the Edit Categories string by passing 0 for the `editingStrID` parameter, or include the item by passing `categoryEditStrID`.

**See Also** [CategorySelectV10](#)

## CategorySelectV10

- Purpose** Process the selection and editing of categories.
- Declared In** `Category.h`
- Prototype** `Boolean CategorySelectV10 (DmOpenRef db,  
const FormType *frm, UInt16 ctlID, UInt16 lstID,  
Boolean title, UInt16 *categoryP,  
Char *categoryName)`
- Parameters**
- > `db` Open database containing the categories.
  - > `frm` Form that contains the category popup list.
  - > `ctlID` ID of the popup trigger.
  - > `lstID` ID of the popup list.
  - > `title` `true` to have an "All" list item. (In general, if the trigger is in the form's title bar, it should have an "All" item. If the trigger is elsewhere in the form, it should not.)

## Categories

### Category Functions

---

<-> categoryP      Index of the selected category. The index is the index into the `categoryLabels` array.

<-> categoryName      Name of the selected category.

**Result**      Returns `true` if any of the following conditions are true:

- The current category is renamed.
- The current category is deleted.
- The current category is merged with another category.

**Compatibility**      This function corresponds to the Palm OS 1.0 version of [CategorySelect](#). It is obsolete.

## CategorySetName

**Purpose**      Change the category name in the [AppInfoType](#) structure, or delete a category.

**Declared In**      `Category.h`

**Prototype**      `void CategorySetName (DmOpenRef db, UInt16 index, const Char *nameP)`

**Parameters**

-> db	Open database containing the category to change.
-> index	Index of category to rename.
-> nameP	The new category name (null-terminated), or NULL to delete the category.

**Result**      Returns nothing.

**Comments**      The [CategoryEdit](#) function calls this function when a user creates a new category or renames an existing category in the Edit Categories dialog. Your application does not have to call it directly.

**Compatibility**      Implemented only if [2.0 New Feature Set](#) is present.

## CategorySetTriggerLabel

<b>Purpose</b>	Set the label displayed by the category popup trigger.				
<b>Declared In</b>	Category.h				
<b>Prototype</b>	<pre>void CategorySetTriggerLabel (ControlType *ctl, Char *name)</pre>				
<b>Parameters</b>	<table><tr><td>&lt;-&gt; ctl</td><td>Pointer to control object (popup trigger) to relabel.</td></tr><tr><td>&lt;-&gt; name</td><td>Pointer to the name of the new category.</td></tr></table>	<-> ctl	Pointer to control object (popup trigger) to relabel.	<-> name	Pointer to the name of the new category.
<-> ctl	Pointer to control object (popup trigger) to relabel.				
<-> name	Pointer to the name of the new category.				
<b>Result</b>	Returns nothing.				
<b>Comments</b>	The CategorySetTriggerLabel function calls the <a href="#">CategoryTruncateName</a> function to truncate the category name to the maximum length. The maximum length varies, depending upon which ROM is installed in the device.				
	<hr/> <b>NOTE:</b> This function passes the <code>name</code> parameter to the <code>CategoryTruncateName</code> function, which means that the <code>name</code> value must be modifiable. <code>CategorySetTriggerLabel</code> does not make a copy of the string passed, so you must ensure that the string remains valid until the form is closed. <hr/>				
<b>See Also</b>	<a href="#">CtlSetLabel</a>				

## CategoryTruncateName

- Purpose** Truncate a category name so that it's short enough to display. The category name is truncated if it's longer than `maxWidth`.
- Declared In** `Category.h`
- Prototype** `void CategoryTruncateName (Char *name, UInt16 maxWidth)`
- Parameters**
- |                             |  |
|-----------------------------|--|
| <code>&lt;-&gt; name</code> | Category name to truncate. Upon return, contains the truncated name. |
| <code>-&gt; maxWidth</code> | Maximum size, in pixels, of truncated category (including ellipsis). |
- Result** Returns nothing.

# Clipboard

---

This chapter provides reference material for the clipboard API defined in `Clipboard.h`. It covers:

- [Clipboard Data Structures](#)
- [Clipboard Functions](#)

## Clipboard Data Structures

### ClipboardFormatType

The `ClipboardFormatType` enum specifies the type of data to add to the clipboard or retrieve from the clipboard.

```
enum clipboardFormats {
    clipboardText,
    clipboardInk,
    clipboardBitmap };
typedef enum clipboardFormats
    ClipboardFormatType;
```

#### Value Descriptions

<code>clipboardText</code>	Textual data. This is the most commonly used clipboard.
<code>clipboardInk</code>	Reserved.
<code>clipboardBitmap</code>	Bitmap data.

Clipboards for each type of data are separately maintained. That is, if you add a string of text to the clipboard, then add a bitmap, then ask to retrieve a `clipboardText` item from the clipboard, you will receive the string you added before the bitmap; the bitmap does not overwrite textual data and vice versa.

## Clipboard Functions

### ClipboardAddItem

**Purpose** Add the item passed to the specified clipboard. Replaces the current item (if any) of that type.

**Declared In** `Clipboard.h`

**Prototype**  
`void ClipboardAddItem  
(const ClipboardFormatType format,  
const void *ptr, UInt16 length)`

**Parameters**

-> format	Text, ink, bitmap, etc. See <a href="#">ClipboardFormatType</a> .
-> ptr	Pointer to the item to place on the clipboard.
-> length	Size in bytes of the item to place on the clipboard.

**Result** Returns nothing.

**Comments** The clipboard makes a copy of the data that you pass to this function. Thus, you may free any data that you've passed to the clipboard without destroying the contents of the clipboard. You may also add constant data or stack-based data to the clipboard.

---

**WARNING!** You can't add null-terminated strings to the clipboard.

---

**See Also** [FldCut](#), [FldCopy](#)

## ClipboardAppendItem

<b>Purpose</b>	Append data to the item on the clipboard.						
<b>Declared In</b>	Clipboard.h						
<b>Prototype</b>	<pre>Err ClipboardAppendItem (const ClipboardFormatType format, const void *ptr, UInt16 length)</pre>						
<b>Parameters</b>	<table><tr><td>-&gt; format</td><td>Text, ink, bitmap, etc. See <a href="#">ClipboardFormatType</a>. This function is intended to be used only for the clipboardText format.</td></tr><tr><td>-&gt; ptr</td><td>Pointer to the data to append to the item on the clipboard.</td></tr><tr><td>-&gt; length</td><td>Size in bytes of the data to append to the clipboard.</td></tr></table>	-> format	Text, ink, bitmap, etc. See <a href="#">ClipboardFormatType</a> . This function is intended to be used only for the clipboardText format.	-> ptr	Pointer to the data to append to the item on the clipboard.	-> length	Size in bytes of the data to append to the clipboard.
-> format	Text, ink, bitmap, etc. See <a href="#">ClipboardFormatType</a> . This function is intended to be used only for the clipboardText format.						
-> ptr	Pointer to the data to append to the item on the clipboard.						
-> length	Size in bytes of the data to append to the clipboard.						
<b>Result</b>	0 upon success or memErrNotEnoughSpace if there is not enough space to append the data to the clipboard.						
<b>Comments</b>	<p>This function differs from <a href="#">ClipboardAddItem</a> in that it does not overwrite data already on the clipboard. It allows you to create a large text item on the clipboard from several small disjointed pieces. When other applications retrieve the text from the clipboard, it's retrieved as a single unit.</p> <p>This function simply appends the specified item to the item already on the clipboard without attempting to parse the format. It's assumed that you'll call it several times over a relatively short interval and that no other application will attempt to retrieve text from the clipboard before your application is finished appending.</p>						
<b>Compatibility</b>	Implemented only if <a href="#">3.2 New Feature Set</a> is present.						

## ClipboardGetItem

- Purpose** Return the handle of the contents of the clipboard of a specified type and the length of a clipboard item.
- Declared In** `Clipboard.h`
- Prototype** `MemHandle ClipboardGetItem  
(const ClipboardFormatType format, UInt16 *length)`
- Parameters**
- |           |   |
|-----------|---|
| -> format | Text, ink, bitmap, etc. See <a href="#">ClipboardFormatType</a> . |
| <- length | The length in bytes of the clipboard item is returned here.       |
- Result** Handle of the clipboard item.
- Comments** The handle returned is a handle to the actual clipboard chunk. It is not suitable for passing to any API that modifies memory (such as [FldSetTextHandle](#)). Consider this to be read-only access to the chunk. Copy the contents of the clipboard to your application's own storage as soon as possible and use that reference instead of the handle returned by this function.
- Don't free the handle returned by this function; it is freed when a new item is added to the clipboard.
- Text retrieved from the clipboard does not have a null terminator. You must use the `length` parameter to determine the length in bytes of the string you've retrieved.

# Controls

---

This chapter describes the control object API as declared in the header file `Control.h`. It discusses the following topics:

- [Control Data Structures](#)
- [Control Resources](#)
- [Control Functions](#)

For more information on controls, see the section “[Offscreen Windows](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Control Data Structures

### ButtonFrameType

The `ButtonFrameType` enum specifies the border style for the button. It defines values for the `frame` field of [ControlAttrType](#).

```
enum buttonFrames {noButtonFrame,
                  standardButtonFrame, boldButtonFrame,
                  rectangleButtonFrame};
typedef enum buttonFrames ButtonFrameType;
```

#### Value Descriptions

<code>noButtonFrame</code>	The button has no border.
<code>standardButtonFrame</code>	Standard button rectangular border with rounded corners.
<code>boldButtonFrame</code>	Bolded rectangular border with rounded corners.
<code>rectangleButtonFrame</code>	Rectangular border with square corners.

## Controls

### Control Data Structures

---

## ControlAttrType

The `ControlAttrType` bit field specifies the control's visible characteristics. It is defined as follows:

```
typedef struct {
    UInt8 usable      :1;
    UInt8 enabled     :1;
    UInt8 visible     :1;
    UInt8 on          :1;
    UInt8 leftAnchor  :1;
    UInt8 frame       :3;
    UInt8 drawnAsSelected : 1;
    UInt8 graphical   :1;
    UInt8 vertical    :1;
} ControlAttrType;
```

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `ControlAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

Your code should treat the `ControlAttrType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

### Field Descriptions

<code>usable</code>	If 0, the control is not considered to be part of the interface of the current application, and it doesn't appear on screen. You can use <a href="#">CtlSetUsable</a> , <a href="#">CtlShowControl</a> , or <a href="#">CtlHideControl</a> to set or clear this value.
<code>enabled</code>	If 0, the control is visible but doesn't respond to the pen. This value is set by <a href="#">CtlSetEnabled</a> and returned by <a href="#">CtlEnabled</a> .

visible	Set and cleared internally when the control is drawn ( <a href="#">CtlDrawControl</a> ) and erased ( <a href="#">CtlEraseControl</a> ).
on	If set, the control has the value “on.” For example, a check box that has the on value has a check mark displayed in it. Use <a href="#">CtlGetValue</a> and <a href="#">CtlSetValue</a> to retrieve and set this value.
leftAnchor	Used by controls that expand and shrink their width when the label is changed. If this attribute is set, the left bound of the control is fixed.
frame	The type of frame drawn around the button controls. See <a href="#">ButtonFrameType</a> for possible values. Only button controls use this attribute; for all other controls, the <a href="#">ControlStyleType</a> determines the frame.
drawnAsSelected	Used on Palm OS® release 3.5 for button controls that contain no text (indicating that the button is displayed on top of a bitmap). If set, the button is drawn as inverted. If clear, the button is drawn normally.
graphical	If set, the control is a graphical control, slider, or feedback slider.
vertical	Not currently used.

**Compatibility** The `drawnAsSelected`, `graphical`, and `vertical` attributes are only present if [3.5 New Feature Set](#) is present.

## ControlPtr

The `ControlPtr` is a pointer to a [ControlType](#) structure.

## Controls

### Control Data Structures

---

```
typedef ControlType* ControlPtr;
```

## ControlStyleType

The `ControlStyleType` enum specifies values for the [ControlType](#) style field, which specifies the type of the control (button, push button, and so on).

```
enum controlStyles {buttonCtl, pushButtonCtl,
checkboxCtl, popupTriggerCtl,
selectorTriggerCtl, repeatingButtonCtl,
sliderCtl, feedbackSliderCtl};
typedef enum controlStyles ControlStyleType;
```

## Value Descriptions

<code>buttonCtl</code>	Button. Buttons display a text label in a box. The <a href="#">ButtonFrameType</a> specifies the type of box.
<code>pushButtonCtl</code>	Push button. Selecting a push button inverts its display so that it appears highlighted.
<code>checkboxCtl</code>	Check box. Check boxes display a setting of either on (checked) or off (unchecked)
<code>popupTriggerCtl</code>	Popup trigger. Popup triggers display a graphic element followed by a text label. They are used to display popup lists.
<code>selectorTriggerCtl</code>	Selector trigger. Selector triggers display a text label surrounded by a gray rectangular frame. The control expands or contracts to the width of the new label.
<code>repeatingButtonCtl</code>	Repeating button. Repeating buttons look like buttons; however, a repeating button is repeatedly selected if the user holds the pen on it.

sliderCtl	Slider. Sliders display two bitmaps: one representing the current value (the thumb), and another representing the scale of available values. The user can slide the thumb to the left or the right to change the value.
feedbackSliderCtl	Feedback slider. A feedback slider looks like a slider; however, a feedback slider sends events each time the thumb moves while the pen is still down. A regular slider sends an event only when the user releases the pen.

**Compatibility** The sliderCtl and feedbackSliderCtl values are only defined if [3.5 New Feature Set](#) is present.

## ControlType

The ControlType structure defines the type and characteristics of a control. It is defined as follows:

```
typedef struct {
    UInt16          id;
    RectangleType   bounds;
    Char *          text;
    ControlAttrType attr;
    ControlStyleType style;
    FontID          font;
    UInt8          group;
    UInt8          reserved;
} ControlType;
```

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the ControlType structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

## Controls

### Control Data Structures

---

Your code should treat the `ControlType` structure as opaque. The fields in the struct are set by values you specify when you create the control resource, and they typically do not change. Use the functions specified in the descriptions below to retrieve and set the values. Do not attempt to change structure member values directly.

#### Field Descriptions

<code>id</code>	ID value you specified when you created the control resource.
<code>bounds</code>	Bounds of the control, in window-relative coordinates. The control's text label is clipped to the control's bounds. The control's frame is drawn around (outside) the bounds of the control. <a href="#">FrmGetObjectBounds</a> and <a href="#">FrmSetObjectBounds</a> retrieve and set this value.
<code>text</code>	Pointer to the control's label. If <code>text</code> is <code>NULL</code> , the control has no label. Use <a href="#">CtlGetLabel</a> and <a href="#">CtlSetLabel</a> to retrieve and set this value.
<code>attr</code>	Control attributes. See <a href="#">ControlAttrType</a> .
<code>style</code>	Style of the control. See <a href="#">ControlStyleType</a> .
<code>font</code>	Font to use to draw the control's label.
<code>group</code>	Group ID of a push button or a check box that is part of an exclusive group. The control routines don't automatically turn one control off when another is selected. It's up to the application or a higher-level object, like a dialog box, to manage this.
<code>reserved</code>	Reserved for future use.

#### GraphicControlType

The `GraphicControlType` struct defines a graphical control. A graphical control is like any other control except that it displays a bitmap in place of the text label.

```
typedef struct GraphicControlType {
    UInt16          id;
    RectangleType   bounds;
    DmResID         bitmapID;
    DmResID         selectedBitmapID;
    ControlAttrType attr;
    ControlStyleType style;
    FontID          unused;
    UInt8           group;
    UInt8           reserved;
} GraphicControlType;
```

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `GraphicControlType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

Your code should treat the `GraphicControlType` structure as opaque. The fields in the struct are set by values you specify when you create the control resource, and they typically do not change. Use the functions specified in the descriptions below to retrieve and set the values. Do not attempt to change structure member values directly.

### Field Descriptions

<code>id</code>	ID value you specified when you created the control resource.
<code>bounds</code>	Bounds of the control, in window-relative coordinates. The control's frame is drawn around (outside) the bounds of the control. <a href="#">FrmGetObjectBounds</a> and <a href="#">FrmSetObjectBounds</a> retrieve and set this value.
<code>bitmapID</code>	Resource ID of the bitmap to display in the button. You can use <a href="#">CtlSetGraphics</a> to change this value.

## Controls

### Control Data Structures

---

<code>selectedBitmapID</code>	If the button should show a different bitmap when selected, this field contains the resource ID of that bitmap. You typically use this field for push buttons or repeating buttons. <a href="#">CtlSetGraphics</a> can change this value.
<code>attr</code>	Control attributes. See <a href="#">ControlAttrType</a> . For a graphical control, the graphical attribute must be set. The APIs described in the <a href="#">ControlAttrType</a> section can be used to access the bitfields here. Because the <a href="#">ControlAttrType</a> APIs take a <code>ControlType*</code> as an argument, the <code>GraphicControlType*</code> should be cast to a <code>ControlType*</code> when making the API calls.
<code>style</code>	Style of the control. See <a href="#">ControlStyleType</a> . A graphical control can be any type of control other than <code>checkboxCtl</code> .
<code>unused</code>	Unused.
<code>group</code>	Group ID of a push button that is part of an exclusive group. The control routines don't automatically turn one control off when another is selected. It's up to the application or a higher-level object, like a dialog box, to manage this.
<code>reserved</code>	Reserved for future use.

**Compatibility** This struct is defined only if [3.5 New Feature Set](#) is present.

## SliderControlType

The `SliderControlType` struct defines a slider control or a feedback slider control.

```
typedef struct SliderControlType {
    UInt16          id;
    RectangleType   bounds;
    DmResID         thumbID;
    DmResID         backgroundID;
    ControlAttrType attr;
    ControlStyleType style;
    UInt8          reserved;
    Int16          minValue;
    Int16          maxValue;
    Int16          pageSize;
    Int16          value;
    MemPtr         activeSliderP;
} SliderControlType;
```

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `SliderControlType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

Your code should treat the `SliderControlType` structure as opaque. The fields in the struct are set by values you specify when you create the control resource, and they typically do not change. You can use [CtlSetSliderValues](#) to set new minimum, maximum, page size, and current values, and [CtlGetSliderValues](#) to retrieve these values. Do not attempt to change structure member values directly.

### Field Descriptions

<code>id</code>	ID value you specified when you created the control resource.
<code>bounds</code>	Bounds of the control, in window-relative coordinates. <a href="#">FrmGetObjectBounds</a> and <a href="#">FrmSetObjectBounds</a> retrieve and set this value.

## Controls

### Control Data Structures

---

<code>thumbID</code>	Resource ID of the bitmap to use for the slider knob (called the “thumb”). If <code>NULL</code> , the default bitmap is used.
<code>backgroundID</code>	Resource ID of the bitmap to use for the slider background. If <code>NULL</code> , the default bitmap is used.
<code>attr</code>	Control attributes. See <a href="#">ControlAttrType</a> . For a slider, the graphical attribute is set. The APIs described in the <code>ControlAttrType</code> section can be used to access the bitfields here. Because the <code>ControlAttrType</code> APIs take a <code>ControlType*</code> as an argument, the <code>SliderControlType*</code> should be cast to a <code>ControlType*</code> when making the API calls.
<code>style</code>	Style of the control. See <a href="#">ControlStyleType</a> . Must be <code>sliderCtl</code> or <code>feedbackSliderCtl</code> .
<code>reserved</code>	Reserved for future use.
<code>minValue</code>	Value of the slider when the thumb is all the way to the left.
<code>maxValue</code>	Value of the slider when the thumb is all the way to the right.
<code>pageSize</code>	Amount by which to increase or decrease the slider value when the user taps to the right or left of the thumb.
<code>value</code>	Current value represented by the slider. Use <a href="#">CtlGetValue</a> and <a href="#">CtlSetValue</a> to retrieve and set this value.
<code>activeSliderP</code>	Pointer to a memory location used when the slider is active. A slider is active if it is currently being drawn or if it is tracking the pen. If the slider is inactive, this pointer is <code>NULL</code> .

**Compatibility** This struct is defined only if [3.5 New Feature Set](#) is present.

## Control Resources

Different resources are associated with different controls, as follows:

- Button—[Button Resource](#) (tBTN)
- Popup trigger—[Popup Trigger Resource](#) (tPUT)
- Selector trigger—[Selector Trigger Resource](#) (tSLT)
- Repeat control—[Repeating Button Resource](#) (tREP)
- Push button—[Push Button Resource](#) (tPBN)
- Check box—[Check Box Resource](#) (tCBX)
- Slider—Slider Resource (tsld)
- Feedback slider—Feedback Slider Resource (tslf)

## Control Functions

### CtlDrawControl

<b>Purpose</b>	Draw a control object (and the text or graphic in it) on screen.
<b>Declared In</b>	<code>Control.h</code>
<b>Prototype</b>	<code>void CtlDrawControl (ControlType *controlP)</code>
<b>Parameters</b>	<code>-&gt; controlP</code> Pointer to the control object to draw. (See <a href="#">ControlType</a> .)
<b>Result</b>	Returns nothing.
<b>Comments</b>	The control is drawn only if its <code>usable</code> attribute is <code>true</code> . This function sets the <code>visible</code> attribute to <code>true</code> .
<b>Compatibility</b>	In releases prior to Palm OS® 3.5, it is common to create graphical buttons by drawing a button with no text label on top of a bitmap. If <a href="#">3.5 New Feature Set</a> is present, you should use graphical controls instead. (See <a href="#">GraphicControlType</a> .) <code>CtlDrawControl</code> attempts

## Controls

### Control Functions

---

to provide backward compatibility for the old-style graphical buttons.

**See Also** [CtlSetUsable](#), [CtlShowControl](#)

## CtlEnabled

**Purpose** Return true if the control responds to the pen.

**Declared In** `Control.h`

**Prototype** `Boolean CtlEnabled (const ControlType *controlP)`

**Parameters** `-> controlP` Pointer to control object. (See [ControlType](#).)

**Result** Returns true if the controls object responds to the pen; false if not.

**Comments** This function provides no indication of whether the control is visible on the screen. A control that doesn't respond to the pen may be visible, and if so, its appearance is no different from controls that do respond to the pen. You might use such a control to display some state of your application that cannot be modified.

**See Also** [CtlSetEnabled](#)

## CtlEraseControl

**Purpose** Erase a usable and visible control object and its frame from the screen.

**Declared In** `Control.h`

**Prototype** `void CtlEraseControl (ControlType *controlP)`

**Parameters** `-> controlP` Pointer to control object to erase. (See [ControlType](#).)

**Comments** This function sets the `visible` attribute to `false`. If [3.5 New Feature Set](#) is present, it also sets the `drawnAsSelected` attribute to `false`.  
Don't call this function directly; instead, use [FrmHideObject](#), which calls this function.

## **CtlGetLabel**

**Purpose** Return a character pointer to a control's text label.

**Declared In** `Control.h`

**Prototype**  
`const Char *CtlGetLabel  
(const ControlType *controlP)`

**Parameters** `-> controlP` Pointer to control object. (See [ControlType](#).)

**Result** Returns a pointer to a null-terminated string.

**Comments** Make sure that `controlP` is not a graphical control or a slider control. The graphical control and slider control structures do not contain a text label field.

**See Also** [CtlSetLabel](#)

## **CtlGetSliderValues**

**Purpose** Return current values used by a slider control.

**Declared In** `Control.h`

**Prototype**  
`void CtlGetSliderValues (const ControlType *ctlP,  
UInt16 *minValueP, UInt16 *maxValueP,  
UInt16 *pageSizeP, UInt16 *valueP)`

**Parameters** `-> ctlP` Pointer to a control object. (See [ControlType](#).)

## Controls

### Control Functions

---

<code>&lt;- minValueP</code>	The slider's minimum value. Pass <code>NULL</code> if you don't want to retrieve this value.
<code>&lt;- maxValueP</code>	The slider's maximum value. Pass <code>NULL</code> if you don't want to retrieve this value.
<code>&lt;- pageSizeP</code>	The slider's page size value. Pass <code>NULL</code> if you don't want to retrieve this value.
<code>&lt;- valueP</code>	The slider's current value. Pass <code>NULL</code> if you don't want to retrieve this value.

**Result** Returns nothing. The slider's values are returned in the parameters to this function.

**Comments** If `ctlP` is not a slider or a feedback slider, this function immediately returns.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [CtlSetSliderValues](#), [SliderControlType](#)

## CtlGetValue

**Purpose** Return the current value of the specified control.

**Declared In** `Control.h`

**Prototype** `Int16 CtlGetValue (const ControlType *controlP)`

**Parameters** `-> controlP` Pointer to a control object. (See [ControlType](#).)

**Result** Returns the current value of the control. For most controls the return value is either 0 (off) or 1 (on). For sliders, this function returns the value of the `value` field.

**See Also** [CtlSetValue](#), [FrmGetControlGroupSelection](#), [FrmSetControlGroupSelection](#), [FrmGetControlValue](#), [FrmSetControlValue](#)

## CtlHandleEvent

<b>Purpose</b>	Handle event in the specified control object.
<b>Declared In</b>	<code>Control.h</code>
<b>Prototype</b>	<code>Boolean CtlHandleEvent (ControlType *controlP, EventType *pEvent)</code>
<b>Parameters</b>	<code>-&gt; controlP</code> Pointer to control object. (See <a href="#">ControlType</a> .) <code>-&gt; pEvent</code> Pointer to an EventType structure.
<b>Result</b>	Returns <code>true</code> if an event is handled by this function. Events that are handled are: <ul style="list-style-type: none"><li>• <a href="#">penDownEvent</a> — If the pen is within the bounds of the control</li><li>• <a href="#">ctlEnterEvent</a>, <a href="#">ctlRepeatEvent</a>, and <a href="#">ctlExitEvent</a> — If the control ID in the event data matches the control's ID.</li></ul>
<b>Comments</b>	<p>The control object must be usable, visible, and respond to the pen for this function to handle the event.</p> <p>When this routine receives a <code>penDownEvent</code>, it checks if the pen position is within the bounds of the control object. If it is, a <code>ctlEnterEvent</code> is added to the event queue and the routine exits.</p> <p>When this routine receives a <code>ctlEnterEvent</code>, the control object is redrawn as necessary as either selected or deselected, depending on its previous state.</p> <p>When this routine receives a <code>ctlEnterEvent</code> or <code>ctlRepeatEvent</code>, it checks that the control ID in the passed event record matches the ID of the specified control. If they match, this routine tracks the pen until it comes up or until it leaves the object's bounds. When that happens, <code>ctlSelectEvent</code> is sent to the event queue if the pen came up in the bounds of the control. If the pen exits the bounds, a <code>ctlExitEvent</code> is sent to the event queue.</p>

## Controls

### Control Functions

---

#### CtlHideControl

- Purpose** Set a control's usable attribute to false and erase the control from the screen.
- Declared In** `Control.h`
- Prototype** `void CtlHideControl (ControlType *controlP)`
- Parameters** `-> controlP` Pointer to the control object to hide. (See [ControlType](#).)
- Result** Returns nothing.
- Comments** A control that is not usable doesn't draw and doesn't respond to the pen.  
This function is the same as [CtlEraseControl](#) except that it also sets usable to false (in addition to setting visible to false).  
Don't call this function directly; instead, use [FrmHideObject](#), which performs the same function and works for all user interface objects.
- See Also** [CtlShowControl](#)

#### CtlHitControl

- Purpose** Simulate tapping a control. This function adds a [ctlSelectEvent](#) to the event queue.
- Declared In** `Control.h`
- Prototype** `void CtlHitControl (const ControlType *controlP)`
- Parameters** `-> controlP` Pointer to a control object. (See [ControlType](#).)
- Result** Returns nothing.

**Comments** Useful for testing.

## **CtlNewControl**

**Purpose** Create a new control object dynamically and install it in the specified form.

**Declared In** `Control.h`

**Prototype** `ControlType *CtlNewControl (void **formPP, UInt16 ID, ControlStyleType style, const Char *textP, Coord x, Coord y, Coord width, Coord height, FontID font, UInt8 group, Boolean leftAnchor)`

**Parameters**

<code>&lt;-&gt; formPP</code>	Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the <code>formPP</code> value may change if the object moves in memory. In subsequent calls, always use the new <code>formPP</code> value returned by this function.
<code>-&gt; ID</code>	Symbolic ID of the control.
<code>-&gt; style</code>	A <a href="#">ControlStyleType</a> value specifying the kind of control to create: button, push button, repeating button, check box, popup trigger, or popup selector. To create a graphical control or slider control dynamically, use <a href="#">CtlNewGraphicControl</a> or <a href="#">CtlNewSliderControl</a> , respectively.

## Controls

### Control Functions

---

- > `textP`      Pointer to the control's label text. If `textP` is `NULL`, the control has no label. Only buttons, push buttons, and text boxes have text labels. Because the contents of this pointer are copied into their own buffer, you can free the `textP` pointer any time after the `CtlNewControl` function returns. The buffer into which this string is copied is freed automatically when you remove the control from the form or delete the form.
- > `x`            Horizontal coordinate of the upper-left corner of the control's boundaries, relative to the window in which it appears.
- > `y`            Vertical coordinate of the upper-left corner of the control's boundaries, relative to the window in which it appears.
- > `width`        Width of the control, expressed in pixels. Valid values are 1–160. If the value of either of the `width` or `height` parameters is 0, the control is sized automatically as necessary to display the text passed as the value of the `text` parameter.
- > `height`       Height of the control, expressed in pixels. Valid values are 1–160. If the value of either of the `width` or `height` parameters is 0, the control is sized automatically as necessary to display the text passed as the value of the `text` parameter.
- > `font`         Font used to draw the control's label.
- > `group`        Group ID of a push button or a check box that is part of an exclusive group. The control routines don't turn one control off automatically when another is selected. It's up to the application or a higher-level object, such as a dialog box, to manage this.

-> `leftAnchor` `true` specifies that the left bound of this control is fixed. This attribute is used by controls that resize dynamically in response to label text changes.

**Result** Returns a pointer to the new control.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [CtlValidatePointer](#), [FrmRemoveObject](#)

## **CtlNewGraphicControl**

**Purpose** Create a new graphical control dynamically and install it in the specified form.

**Declared In** `Control.h`

**Prototype**

```
GraphicControlType *CtlNewGraphicControl
(void **formPP, UInt16 ID,
ControlStyleType style, DmResID bitmapID,
DmResID selectedBitmapID, Coord x, Coord y,
Coord width, Coord height, UInt8 group,
Boolean leftAnchor)
```

**Parameters**

<code>&lt;-&gt; formPP</code>	Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the <code>formPP</code> value may change if the object moves in memory. In subsequent calls, always use the new <code>formPP</code> value returned by this function.
-> <code>ID</code>	Symbolic ID of the control.
-> <code>style</code>	A <a href="#">ControlStyleType</a> value specifying the kind of control to create: button, push button, popup trigger, repeating button, or popup selector. Graphic controls cannot be check boxes.

## Controls

### Control Functions

---

- > `bitmapID` Resource ID of the bitmap to display on the control.
- > `selectedBitmapID` Resource ID of the bitmap to display when the control is selected, if different from `bitmapID`.
- > `x` Horizontal coordinate of the upper-left corner of the control's boundaries, relative to the window in which it appears.
- > `y` Vertical coordinate of the upper-left corner of the control's boundaries, relative to the window in which it appears.
- > `width` Width of the control, expressed in pixels. Valid values are 1–160.
- > `height` Height of the control, expressed in pixels. Valid values are 1–160.
- > `group` Group ID of a push button that is part of an exclusive group. The control routines don't turn one control off automatically when another is selected. It's up to the application or a higher-level object, such as a dialog box, to manage this.
- > `leftAnchor` `true` specifies that the left bound of this control is fixed.

**Result** Returns a pointer to the new graphical control. See [GraphicControlType](#).

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [CtlNewSliderControl](#), [CtlNewControl](#), [CtlValidatePointer](#), [FrmRemoveObject](#)

## CtlNewSliderControl

<b>Purpose</b>	Create a new slider or feedback slider dynamically and install it in the specified form.												
<b>Declared In</b>	Control.h												
<b>Prototype</b>	<pre>SliderControlType *CtlNewSliderControl (void **formPP, UInt16 ID, ControlStyleType style, DmResID thumbID, DmResID backgroundID, Coord x, Coord y, Coord width, Coord height, UInt16 minValue, UInt16 maxValue, UInt16 pageSize, UInt16 value)</pre>												
<b>Parameters</b>	<table><tr><td>&lt;-&gt; formPP</td><td>Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the formPP value may change if the object moves in memory. In subsequent calls, always use the new formPP value returned by this function.</td></tr><tr><td>-&gt; ID</td><td>Symbolic ID of the slider.</td></tr><tr><td>-&gt; style</td><td>Either sliderCtl or feedbackSliderCtl. See <a href="#">ControlStyleType</a>.</td></tr><tr><td>-&gt; thumbID</td><td>Resource ID of the bitmap to display as the slider thumb. The slider thumb is the knob that the user can drag to change the slider's value. To use the default thumb bitmap, pass NULL for this parameter.</td></tr><tr><td>-&gt; backgroundID</td><td>Resource ID of the bitmap to display as the slider background. To use the default background bitmap, pass NULL for this parameter.</td></tr><tr><td>-&gt; x</td><td>Horizontal coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.</td></tr></table>	<-> formPP	Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the formPP value may change if the object moves in memory. In subsequent calls, always use the new formPP value returned by this function.	-> ID	Symbolic ID of the slider.	-> style	Either sliderCtl or feedbackSliderCtl. See <a href="#">ControlStyleType</a> .	-> thumbID	Resource ID of the bitmap to display as the slider thumb. The slider thumb is the knob that the user can drag to change the slider's value. To use the default thumb bitmap, pass NULL for this parameter.	-> backgroundID	Resource ID of the bitmap to display as the slider background. To use the default background bitmap, pass NULL for this parameter.	-> x	Horizontal coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.
<-> formPP	Pointer to the pointer to the form in which the new control is installed. This value is not a handle; that is, the formPP value may change if the object moves in memory. In subsequent calls, always use the new formPP value returned by this function.												
-> ID	Symbolic ID of the slider.												
-> style	Either sliderCtl or feedbackSliderCtl. See <a href="#">ControlStyleType</a> .												
-> thumbID	Resource ID of the bitmap to display as the slider thumb. The slider thumb is the knob that the user can drag to change the slider's value. To use the default thumb bitmap, pass NULL for this parameter.												
-> backgroundID	Resource ID of the bitmap to display as the slider background. To use the default background bitmap, pass NULL for this parameter.												
-> x	Horizontal coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.												

## Controls

### Control Functions

---

-> y	Vertical coordinate of the upper-left corner of the slider's boundaries, relative to the window in which it appears.
-> width	Width of the slider, expressed in pixels. Valid values are 1–160.
-> height	Height of the slider, expressed in pixels. Valid values are 1–160.
-> minValue	Value of the slider when its thumb is all the way to the left.
-> maxValue	Value of the slider when its thumb is all the way to the right.
-> pageSize	Amount by which to increase or decrease the slider's value when the user clicks to the right or left of the thumb.
-> value	The initial value to display in the slider.

**Result** Returns a pointer to the new slider control. See [SliderControlType](#).

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [CtlNewGraphicControl](#), [CtlNewControl](#), [CtlValidatePointer](#), [FrmRemoveObject](#)

## CtlSetEnabled

**Purpose** Set a control as enabled or disabled. Disabled controls do not respond to the pen.

**Declared In** `Control.h`

**Prototype** `void CtlSetEnabled (ControlType *controlP, Boolean usable)`

**Parameters** -> controlP Pointer to a control object. (See [ControlType](#).)

## Controls

### Control Functions

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [GraphicControlType](#)

## CtlSetLabel

**Purpose** Set the current label for the specified control object and redraw the control if it is visible.

**Declared In** `Control.h`

**Prototype** `void CtlSetLabel (ControlType *controlP,  
const Char *newLabel)`

**Parameters**

-> controlP	Pointer to a control object. (See <a href="#">ControlType</a> .)
-> newLabel	Pointer to the new text label. Must be a null-terminated string.

**Result** Returns nothing.

**Comments** This function resizes the width of the control to the size of the new label.

This function stores the newLabel pointer in the control's data structure. It doesn't make a copy of the string that is passed in. Therefore, if you use CtlSetLabel, you must manage the string yourself. You must ensure that it persists for as long as it is being displayed (that is, for as long as the control is displayed or until you call CtlSetLabel with a new string), and you must free the string after it is no longer in use (typically after the form containing the control is freed).

If you never use CtlSetLabel, you do not need to worry about freeing a control's label.

Make sure that controlP is not a graphical control or a slider control. The graphical controls and slider control structures do not

contain a text label field, so attempting to set one will crash your application.

**See Also** [CtlGetLabel](#)

## **CtlSetSliderValues**

**Purpose** Change a slider control's values and redraw the slider if it is visible.

**Declared In** `Control.h`

**Prototype** `void CtlSetSliderValues (ControlType *ctlP,  
const UInt16 *minValueP, const UInt16 *maxValueP,  
const UInt16 *pageSizeP, const UInt16 *valueP)`

**Parameters**

-> <code>ctlP</code>	Pointer to an inactive slider or feedback slider control. (See <a href="#">SliderControlType</a> .)
-> <code>minValueP</code>	Pointer to a new value to use for the slider's minimum or NULL if you don't want to change this value.
-> <code>maxValueP</code>	Pointer to a new value to use for the slider's maximum, or NULL if you don't want to change this value.
-> <code>pageSizeP</code>	Pointer to a new value to use for the slider's page size, or NULL if you don't want to change this value.
-> <code>valueP</code>	Pointer to a new value to use for the current value, or NULL if you don't want to change this value.

**Result** Returns nothing.

**Comments** The control's style must be `sliderCtl` or `feedbackSliderCtl`, and it not be currently tracking the pen. If the slider is currently tracking the pen, use [CtlSetValue](#) to set the value field.

## Controls

### Control Functions

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [CtlGetSliderValues](#), [SliderControlType](#)

## CtlSetUsable

**Purpose** Set a control to usable or not usable.

**Declared In** `Control.h`

**Prototype** `void CtlSetUsable (ControlType *controlP,  
Boolean usable)`

**Parameters**

-> controlP	Pointer to a control object. (See <a href="#">ControlType</a> .)
-> usable	true to have the control be usable; false to have the control be not usable.

**Result** Returns nothing.

**Comments** A control that is not usable doesn't draw and doesn't respond to the pen.

This function doesn't usually update the control.

**See Also** [CtlEraseControl](#), [CtlHideControl](#), [CtlShowControl](#)

## CtlSetValue

**Purpose** Set the current value of the specified control. If the control is visible, it's redrawn.

**Declared In** `Control.h`

**Prototype** `void CtlSetValue (ControlType *controlP,  
Int16 newValue)`

**Parameters**

-> controlP	Pointer to a control object. (See <a href="#">ControlType</a> .)
-------------	--

-> newValue      New value to set for the control. For sliders, specify a value between the slider's minimum and maximum. For graphical controls, push buttons, or check boxes, specify 0 for off, nonzero for on.

**Result**      Returns nothing.

**Comments**      This function works only with graphical controls, sliders, push buttons, and check boxes. If you set the value of any other type of control, the behavior is undefined.

**Compatibility**      Sliders and graphical controls are only supported if [3.5 New Feature Set](#) is present.

**See Also**      [CtlGetValue](#), [FrmGetControlGroupSelection](#), [FrmSetControlGroupSelection](#), [FrmGetControlValue](#), [FrmSetControlValue](#)

## **CtlShowControl**

**Purpose**      Set a control's usable attribute to true and draw the control on the screen. This function calls [CtlDrawControl](#).

**Declared In**      `Control.h`

**Prototype**      `void CtlShowControl (ControlType *controlP)`

**Parameters**      -> controlP      Pointer to a control object. (See [ControlType](#).)

**Result**      Returns nothing.

**Comments**      If the control is already usable, this function is the functional equivalent of [CtlDrawControl](#).

    Sets the `visible` and the `usable` attributes to true. (See [ControlAttrType](#).)

## Controls

### Control Functions

---

Don't use this function directly; instead use [FrmShowObject](#), which does the same thing.

**See Also** [CtlHideControl](#)

## CtlValidatePointer

**Purpose** Returns true if the specified pointer references a valid control object.

**Declared In** `Control.h`

**Prototype** `Boolean CtlValidatePointer  
(const ControlType *controlP)`

**Parameters** `-> controlP` Pointer to a control. (See [ControlType](#).)

**Result** Returns true when passed a valid pointer to a control; otherwise, returns false.

**Comments** For debugging purposes; do not include this function in commercial products. In debug builds, this function displays a dialog and waits for the debugger when an error occurs.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FrmValidatePtr](#), [WinValidateHandle](#)

# Date and Time Selector

---

The Palm OS® UI provides two system resources for accepting date and time input values. These resources are dialog boxes that contain UI gadgetry for entering dates and times. The Palm OS UI also provides routines to manage the interaction with these resources. This chapter describes those functions.

The API described in this chapter is declared in the header files `Day.h`, `SelDay.h`, `SelTime.h`, and `SelTimeZone.h`.

## Date and Time Selections Data Structures

### SelectDayType

```
typedef enum {
    selectDayByDay,           // return d/m/y
    selectDayByWeek,        // return d/m/y with d as
                            // same day of the week
    selectDayByMonth        // return d/m/y with d as
                            // same day of the month
} SelectDayType;
```

### DaySelectorType

```
typedef struct DaySelectorType {
    RectangleType  bounds;
    Boolean        visible;
    UInt8          reserved1;
    Int16          visibleMonth; // month actually
                                // displayed
}
```

## Date and Time Selector

### *Date and Time Selection Functions*

---

```
    Int16          visibleYear; // year actually
                                // displayed
    DateTimeType   selected;
    SelectDayType  selectDayBy;
    UInt8          reserved2;
} DaySelectorType;
```

## HMSTime

```
typedef struct {
    UInt8 hours;
    UInt8 minutes;
    UInt8 seconds;
    UInt8 reserved;
} HMSTime;
```

# Date and Time Selection Functions

## DayDrawDays

- Purpose** Draw only the days-of-the-month portion of a day selector control object.
- Declared In** Day.h
- Prototype** void DayDrawDays  
(const DaySelectorType \*selectorP)
- Parameters** -> selectorP Pointer to the control object to draw.
- Result** Nothing.
- Comments** This function is used when the year or month changes. Only drawing the portion of the control that presents the days of the month avoids the flicker that would occur if the week titles were redrawn.

**Compatibility** If [5.0 New Feature Set](#) is present this function is unimplemented.

**See Also** [DayDrawDaySelector](#)

## DayDrawDaySelector

**Purpose** Draw a day selector control object on screen.

**Declared In** `Day.h`

**Prototype**  
`void DayDrawDaySelector  
(const DaySelectorType *selectorP)`

**Parameters** `-> selectorP` Pointer to the control object to draw.

**Result** Nothing.

**Comments** The control is drawn only if it is usable.

**Compatibility** If [5.0 New Feature Set](#) is present this function is unimplemented.

**See Also** [DayDrawDays](#)

## DayHandleEvent

**Purpose** Handle event in the specified control. This routine handles two types of events, [penDownEvent](#) and [ctlEnterEvent](#).

**Declared In** `Day.h`

**Prototype**  
`Boolean DayHandleEvent  
(DaySelectorType *selectorP,  
const EventType *pEvent)`

**Parameters** `-> selectorP` Pointer to control object.

## Date and Time Selector

### *Date and Time Selection Functions*

---

-> pEvent            Pointer to an EventType structure.

**Result**            true if the event was handled or false if it was not.

Posts a [daySelectEvent](#) with information on whether to use the date.

**Comments**        A date is used if the user selects a day in the visible month.

When this routine receives a [penDownEvent](#), it checks if the pen position is within the bounds of the control object. If it is, a `dayEnterEvent` is added to the event queue and the routine exits.

When this routine receives a `dayEnterEvent`, it checks that the control id in the event record matches the id of the control specified. If they match, this routine will track the pen until it comes up in the bounds in which case `daySelectEvent` is sent.

If the pen exits the bounds a `dayExitEvent` is sent.

## SelectDay

**Purpose**            Display a form showing a date; allow user to select a different date.

**Declared In**       `SelDay.h`

**Prototype**         `Boolean SelectDay  
 (const SelectDayType selectDayBy, Int16 *month,  
 Int16 *day, Int16 *year, const Char *title)`

**Parameters**       `selectDayBy`        The method by which the user should choose the day. Possible values are `selectDayByDay`, `selectDayByWeek`, and `selectDayByMonth`. See [SelectDayType](#)

`<-> month, day, year`  
Month, day, and year selected.

`-> title`            String title for the dialog.

**Result**            true if the OK button was pressed. If true, month, day, and year contain the new date.

## Date and Time Selector

### *Date and Time Selection Functions*

---

`<-> minute`      The minute selected in the form.  
`-> titleP`      A pointer to a string to display as the title.  
Doesn't change as the function executes.

**Result**      Returns `true` if the user selects OK and `false` otherwise. If `true` is returned, the values in `hour` and `minute` have probably been changed.

**Comments**      Use this function instead of `SelectTime` if you want to display a dialog that specifies a single point in time, not a range of time from start to end.

**Compatibility**      Implemented only if [3.1 New Feature Set](#) is present.

**See Also**      [SelectTimeV33](#)

## SelectTime

**Purpose**      Display a form showing a start and end time. Allow the user to select a different time.

**Declared In**      `SelTime.h`

**Prototype**      `Boolean SelectTime (TimeType *startTimeP,  
TimeType * endTimeP, Boolean untimed, const Char  
*titleP, Int16 startOfDay, Int16 endOfDay,  
Int16 startOfDisplay)`

**Parameters**      `<-> startTimeP, endTimeP`      Pointers to values of type `TimeType`. Pass values to display in these two parameters. If the user makes a selection and taps the OK button, the selected values are returned here.  
`-> untimed`      Pass in `true` to indicate that no time is selected. If the user sets the time to no time then `startTimeP` and `endTimeP` are both set to the constant `noTime (-1)`.

- > `titleP`      A pointer to a string to display as the title.  
Doesn't change as the function executes.
- > `startOfDay`    The hour that the hour list displays at its top. To  
see earlier hours, the user can scroll the list up.  
The value must be between 0 to 12, inclusive.
- > `endOfDay`      The hour used when the "All Day" button is  
selected.
- > `startOfDayDisplay`  
First hour initially visible.

**Result**      Returns `true` if the user selects OK and `false` otherwise. If `true` is returned, the values in `hour` and `minute` have probably been changed.

**Comments**    This version of `SelectTime` adds the `endOfDay` and `startOfDayDisplay` functionality.

**Compatibility**    Implemented if [3.5 New Feature Set](#) is present.

**See Also**      [SelectDay](#), [SelectOneTime](#)

## SelectTimeV33

**Purpose**      Display a form showing the time and allow the user to select a different time.

This function is obsolete and should not be used.

## Date and Time Selector

### *Date and Time Selection Functions*

---

**Declared In** SelTime.h

**Prototype** Boolean SelectTimeV33 (TimeType \*startTimeP,  
TimeType \*endTimeP, Boolean untimed,  
const Char \*titleP, Int16 startOfDay)

**Parameters**

- <-> startTimeP, endTimeP  
Pointers to values of type TimeType. Pass values to display in these two parameters. If the user makes a selection and taps the OK button, the selected values are returned here.
- > untimed  
Pass in true to indicate that no time is selected. If the user sets the time to no time then startTimeP and endTimeP are both set to the constant noTime (-1).
- > titleP  
A pointer to a string to display as the title. Doesn't change as the function executes.
- > startOfDay  
The hour that the hour list displays at its top. To see earlier hours, the user can scroll the list up. The value must be between 0 to 12, inclusive.

**Result** Returns true if the user selects OK and false otherwise. If true is returned, the values in hour and minute have probably been changed.

---

**Comments** **NOTE:** Obsolete functions are provided ONLY for backward compatibility; for example, so a 1.0 application will work on 3.x OS releases. New code should not call these routines!

---

**See Also** [SelectDay](#), [SelectOneTime](#)

## SelectTimeZone

<b>Purpose</b>	Display a form that allows the user to select a different time zone.
<b>Declared In</b>	<code>SelTimeZone.h</code>
<b>Prototype</b>	<pre>Boolean SelectTimeZone (Int16 *ioTimeZoneP, LmLocaleType *ioLocaleInTimeZoneP, const Char *titleP, Boolean showTimes, Boolean anyLocale)</pre>
<b>Parameters</b>	<p><code>&lt;-&gt; ioTimeZoneP</code> A pointer to the time zone, given as minutes east of Greenwich Mean Time (GMT). The initial value is used as the initial selection in the form. Upon return, this parameter contains a pointer to the new time zone that the user selected.</p> <p><code>&lt;-&gt; ioLocaleInTimeZoneP</code> A pointer to a locale (see <a href="#">LmLocaleType</a>) that identifies the time zone country. This parameter is used for countries that share a time zone, such as Canada and Chile.</p> <p>If the time zone specified by <code>ioTimeZoneP</code> is specific to a particular country, you do not have to initialize this parameter. Instead, set the <code>anyLocale</code> parameter to <code>true</code> to have this parameter ignored upon entry.</p> <p><code>-&gt; titleP</code> A string to use as the title for the dialog. Pass <code>NULL</code> to use the default title, which is "Set Time Zone".</p> <p><code>-&gt; showTimes</code> If <code>true</code>, the dialog shows the correct times in both the current and newly selected time zones. If <code>false</code>, the dialog doesn't show the current time. Using <code>false</code> provides a larger area for the list of time zones.</p>

## Date and Time Selector

### *Date and Time Selection Functions*

---

-> anyLocale      If true, ignore ioLocaleInTimeZoneP upon entry.

**Result**      Returns true if the user clicked the OK button in the dialog to change the time zone, or false if the user clicked the Cancel button.

**Comments**      The time zones displayed in the form are listed by country. For this reason, if the time zone specified by ioTimeZoneP is shared by several countries, you need to supply a value for ioLocaleTimeZoneP to identify which country should be selected when the list is first displayed. You can use the constant lmAnyLanguage as the value for the language field of the structure pointed to by this parameter.

If you don't care which value is initially selected, pass true for the anyLocale parameter. In this case, the first country that matches the GMT offset given in ioTimeZoneP is selected.

You might want to use the current time zone stored in the system preferences as the initial value for the ioTimeZoneP parameter. To obtain this time zone, do the following:

```
Int16 timeZone =
    (Int16) PrefGetPreference (prefTimeZone);
CountryType timeZoneCountry = (CountryType)
    PrefGetPreference (prefTimeZoneCountry);
LmLocaleType timeZoneLocale;
Boolean change;

timeZoneLocale.country = timeZoneCountry;
timeZoneLocale.language = lmAnyLanguage;
change = SelectTimeZone (&timeZone,
    &timeZoneLocale, NULL, true, false);
```

**Compatibility**      Implemented if [4.0 New Feature Set](#) is present.

# Fields

---

This chapter provides the following information about field objects:

- [Field Data Structures](#)
- [Field Resources](#)
- [Field Functions](#)

The header file `Field.h` declares the API that this chapter describes. For more information on fields, see the section “[Fields](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Field Data Structures

### FieldAttrType

The `FieldAttrType` bit field defines the visible characteristics of the field. The functions [FldGetAttributes](#) and [FldSetAttributes](#) return and set these values. There are other functions that retrieve or set individual attributes defined here. Those functions are noted below.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FieldAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 usable           :1;
    UInt16 visible         :1;
    UInt16 editable        :1;
    UInt16 singleLine      :1;
    UInt16 hasFocus        :1;
```

## Fields

### Field Data Structures

---

```
    UInt16 dynamicSize    :1;
    UInt16 insPtVisible   :1;
    UInt16 dirty          :1;
    UInt16 underlined     :2;
    UInt16 justification  :2;
    UInt16 autoShift      :1;
    UInt16 hasScrollBar   :1;
    UInt16 numeric        :1;
} FieldAttrType;
```

### Field Descriptions

usable	If not set, the field object is not considered part of the current interface of the application, and it doesn't appear on screen. The function <a href="#">FldSetUsable</a> sets this value, but it is better to use <a href="#">FrmShowObject</a> .
visible	Set or cleared internally when the field object is drawn with <a href="#">FldDrawField</a> or <a href="#">FrmShowObject</a> , and erased with <a href="#">FldEraseField</a> or <a href="#">FrmHideObject</a> .
editable	If not set, the field object doesn't accept Graffiti® input or editing commands and the insertion point cannot be positioned with the pen. The text can still be selected and copied.
singleLine	If set, the field is a single line of text high and the text does not wrap when it exceeds the width of the field. If not set, the text wraps to fill multiple lines.
hasFocus	Set internally when the field has the current focus. The blinking insertion point appears in the field that has the current focus. Use the function <a href="#">FrmSetFocus</a> and <a href="#">FldReleaseFocus</a> to set this value.

<code>dynamicSize</code>	<p>If set, a <code>fldHeightChangedEvent</code> is generated whenever the number of lines needs to increase or decrease. Your application needs to respond to this event by adjusting the size of the field's bounding box. If not set, the text wraps to fill more (or less) lines as required, but the event is not generated. <i>Note that this bit does not cause the field to change size automatically; your application must respond to the <code>fldHeightChangedEvent</code> and resize the field itself.</i></p> <p>Set this attribute to <code>false</code> if the <code>Single Line</code> attribute is set.</p>
<code>insPtVisible</code>	<p>If set, the insertion point is scrolled into view. This attribute is set and cleared internally.</p>
<code>dirty</code>	<p>If set, the user has modified the field. The functions <a href="#">FldDirty</a> and <a href="#">FldSetDirty</a> retrieve this field's value.</p>
<code>underlined</code>	<p>If set each line of the field, including blank lines, is underlined. Possible values are defined by the <code>UnderlineModeType</code> defined in <code>Window.h</code>:</p> <ul style="list-style-type: none"><li><code>noUnderline</code></li><li><code>grayUnderline</code></li><li><code>solidUnderline</code></li><li><code>colorUnderline</code></li></ul> <p>Editable text fields generally use <code>grayUnderline</code> as the value.</p> <p>The <code>solidUnderline</code> value is only valid for Palm OS 3.1 and higher.</p> <p>The <code>colorUnderline</code> value is only valid for Palm OS 3.5 and higher.</p>

## Fields

### Field Data Structures

---

<code>justification</code>	Specifies the text alignment. Possible values are <code>leftAlign</code> and <code>rightAlign</code> . (left or right justification only; <code>centerAlign</code> justification is not supported).
<code>autoShift</code>	If set, Graffiti auto-shift rules are applied.
<code>hasScrollBar</code>	If set, the field has a scrollbar. The system sends more frequent <a href="#">fldChangedEvents</a> so the application can adjust the height appropriately.
<code>numeric</code>	If set, only the characters 0 through 9 and associated separators are allowed to be entered in the field. The associated separators are the thousands separator and the decimal character. The values of these two characters depend on the settings in the Formats prefs panel.

## FieldPtr

The `FieldPtr` type defines a pointer to a [FieldType](#) structure.

```
typedef FieldType *FieldPtr;
```

You pass the `FieldPtr` as an argument to all field functions. You can obtain the `FieldPtr` using the function [FrmGetObjectPtr](#) in this way:

```
fldPtr = FrmGetObjectPtr(frm,  
    FrmGetObjectIndex(frm, fldID));
```

where `fldID` is the resource ID assigned when you created the field.

## FieldType

The `FieldType` structure represents a field.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FieldType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16          id;
    RectangleType  rect;
    FieldAttrType  attr;
    Char           *text;
    MemHandle      textHandle;
    LineInfoPtr   lines;
    UInt16        textLen;
    UInt16        textBlockSize;
    UInt16        maxChars;
    UInt16        selFirstPos;
    UInt16        selLastPos;
    UInt16        insPtXPos;
    UInt16        insPtYPos;
    FontID        fontID;
    UInt8         reserved;
} FieldType;
```

Your code should treat the `FieldType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

### Field Descriptions

<code>id</code>	ID value you specified when you created the field resource. This ID value is included as part of the event data of <a href="#">fldEnterEvent</a> .
<code>rect</code>	Position and size of the field object. The functions <a href="#">FldGetBounds</a> , <a href="#">FrmGetObjectBounds</a> , <a href="#">FldSetBounds</a> , and <a href="#">FrmSetObjectBounds</a> retrieve and set this value.

## Fields

### Field Data Structures

---

<code>attr</code>	Field object attributes. (See <a href="#">FieldAttrType</a> .)
<code>text</code>	<p>Pointer to the null-terminated string that is displayed by the field object. The functions <a href="#">FldGetTextPtr</a> and <a href="#">FldSetTextPtr</a> retrieve and set this value (see below).</p> <p>Never set the contents of this string directly; for example, do not pass this pointer as the destination value to a function such as <code>StrCopy</code>.</p>
<code>textHandle</code>	<p>Handle to the stored text or to a database record containing the stored text. The functions <a href="#">FldGetTextHandle</a> and <a href="#">FldSetTextHandle</a> retrieve and set this value.</p> <p>If <code>textHandle</code> is defined, the field calculates the <code>text</code> pointer when it locks the handle. In general, you should only use <a href="#">FldGetTextPtr</a> and <a href="#">FldSetTextPtr</a> on text fields that aren't editable. On editable text fields, use <a href="#">FldGetTextHandle</a> and <a href="#">FldSetTextHandle</a>.</p> <p>Also note that editable text fields allocate the text handle as necessary. If a user starts typing in a field that doesn't have a text handle allocated, the field will allocate one. The field also resizes the text's memory block as necessary when the user adds more text.</p>
<code>lines</code>	<p>Pointer to an array of <code>LineInfoType</code> structures. There is one entry in this array for each visible line of the text. (See <a href="#">LineInfoType</a>.) The field code maintains this array internally; you should never change the <code>lines</code> array yourself.</p> <p>Note that this value is <code>NULL</code> for single line fields, and for fields that do not have an allocated text handle.</p>

`textLen` Length in bytes of the string currently displayed by the field object; the null terminator is excluded. You can retrieve this value with [FldGetTextLength](#).

`textBlockSize` Allocated size of the memory block that holds the field object's text string. You can retrieve this value with [FldGetTextAllocatedSize](#).

Fields allocate memory for the field text as needed, several bytes at a time.

Note that `textBlockSize` may be different from the size of the chunk pointed to by `textHandle`. The `textHandle` may point to a database record that contains, in part, the text displayed by the field. If you called [MemHandleSize](#) on such a `textHandle`, the number returned may be greater than `textBlockSize`.

`maxChars` Maximum number of bytes the field object accepts. The functions [FldGetMaxChars](#) and [FldSetMaxChars](#) retrieve and set this value.

Note the difference between `textLen`, `textBlockSize`, and `maxChars`. `textLen` is the number of bytes of character data that `text` actually holds. `textBlockSize` is the amount of memory currently allocated for the text (which must be greater than or equal to `textLen`), and `maxChars` sets the maximum value that `textBlockSize` and `textLen` can expand to.

For example, if you've created a text field for users to enter their first names in, you might specify that the maximum length of this field is 20 bytes. If a user enters "John" in this field, `textLen` is 4, `textBlockSize` is 16, and `maxChars` is 20.

## Fields

### Field Data Structures

---

<code>selFirstPos</code>	Starting character offset in bytes of the current selection. Use <a href="#">FldGetSelection</a> and <a href="#">FldSetSelection</a> to retrieve and set this value and the <code>selLastPos</code> value.
<code>selLastPos</code>	Ending character offset in bytes of the current selection. When <code>selFirstPos</code> equals <code>selLastPos</code> , there is no selection.
<code>insPtXPos</code>	Horizontal location of the insertion point, given as the offset in bytes into the line indicated by <code>insPtYPos</code> . The functions <a href="#">FldGetInsPtPosition</a> and <a href="#">FldSetInsPtPosition</a> retrieve and set a byte offset calculated from this value. If the insertion point isn't visible—if it's on a line that's either above or below the set of visible lines— <code>insPtXPos</code> is the absolute byte offset of the insertion point.
<code>insPtYPos</code>	Vertical location of the insertion point, given as the display line where the insertion point is positioned. The first display line is zero. The first display line may be different from the first line of text in the field if the field has been scrolled. The functions <a href="#">FldGetInsPtPosition</a> and <a href="#">FldSetInsPtPosition</a> retrieve and set a byte offset calculated from this value. If the insertion point isn't visible—if it's on a line that's either above or below the set of visible lines— <code>insPtYPos</code> is set to 0x8000.
<code>fontID</code>	Font ID for the field. See <code>Font.h</code> for more information. The functions <a href="#">FldGetFont</a> and <a href="#">FldSetFont</a> retrieve and set this value.
<code>reserved</code>	Reserved for future use.

## LineInfoPtr

The `LineInfoPtr` type defines a pointer to the [LineInfoType](#).

```
typedef LineInfoType *LineInfoPtr;
```

## LineInfoType

The `LineInfoType` structure defines an element in the field's `lines` array. The `lines` array contains the field's word wrapping information. There is one element in the array per visible line in the field, including visible lines that contain no text. The field code maintains this array internally; you should never change the `lines` array yourself.

The functions [FldCalcFieldHeight](#), [FldGetVisibleLines](#), [FldRecalculateField](#), and [FldGetNumberOfBlankLines](#) retrieve or set information in this structure. The scrolling functions [FldGetScrollPosition](#), [FldGetScrollValues](#), [FldScrollField](#), and [FldSetScrollPosition](#) also retrieve or set information in this structure.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `LineInfoType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16      start;
    UInt16      length;
} LineInfoType;
```

### Field Descriptions

- |                     |  |
|---------------------|--|
| <code>start</code>  | The byte offset into the <a href="#">FieldType</a> 's <code>text</code> field of the first character displayed by this line. If the line is blank, <code>start</code> is equal to <code>textLen</code> and <code>length</code> is 0. |
| <code>length</code> | The length in bytes of the portion of the string displayed on this line. If the line is blank, the <code>length</code> is 0.   |

## Fields

### Field Resources

---

## Field Resources

The [Field Resource](#) (tFLD) represents a field on screen.

## Field Functions

### FldCalcFieldHeight

**Purpose** Determine the height of a field for a string.

**Declared In** `Field.h`

**Prototype** `UInt16 FldCalcFieldHeight (const Char *chars, UInt16 maxWidth)`

**Parameters**

-> <code>chars</code>	Pointer to a null-terminated string.
-> <code>maxWidth</code>	Maximum line width in pixels.

**Result** Returns the total number of lines needed to draw the string passed.

**Comments** The width of a field is contained in the `rect` member of the [FieldType](#) structure. You can retrieve this value in the following way:

```
FrmGetObjectBounds (frm,
    FrmGetObjectIndex (frm, fldID),
    &myRect);
fieldWidth = myRect.extent.x;
FldCalcFieldHeight (myString, fieldWidth);
```

**See Also** [FldWordWrap](#)

## FldCompactText

- Purpose** Compact the memory block that contains the field's text to release any unused space.
- Declared In** `Field.h`
- Prototype** `void FldCompactText (FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns nothing.
- Comments** As characters are added to the field's text, the block that contains the text is grown. The block is expanded several bytes at a time so that it doesn't have to expand each time a character is added. This expansion may result in some unused space in the text block.
- Applications should call this function on field objects that edit data records in place before the field is unlocked, or at any other time when a compact field is desirable; for example, before writing to the storage heap.
- See Also** [FldGetTextAllocatedSize](#), [FldSetTextAllocatedSize](#)

## FldCopy

- Purpose** Copy the current selection to the text clipboard.
- Declared In** `Field.h`
- Prototype** `void FldCopy (const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns nothing.
- Comments** This function leaves the current selection highlighted.

## Fields

### Field Functions

---

This function replaces anything previously in the text clipboard if there is text to copy. If no text is selected, the function beeps and the clipboard remains intact.

**See Also** [FldCut](#), [FldPaste](#)

## FldCut

**Purpose** Copy the current selection to the text clipboard, delete the selection from the field, and redraw the field.

**Declared In** `Field.h`

**Prototype** `void FldCut (FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns nothing.

**Comments** If text is selected, the text is removed from the field, the field's dirty attribute is set, and anything previously in the text clipboard is replaced by the selected text.

If there is no selection or if the field is not editable, this function beeps.

**See Also** [FldCopy](#), [FldPaste](#), [FldUndo](#)

## FldDelete

<b>Purpose</b>	Delete the specified range of characters from the field and redraw the field.	
<b>Declared In</b>	Field.h	
<b>Prototype</b>	void FldDelete (FieldType *fldP, UInt16 start, UInt16 end)	
<b>Parameters</b>	-> fldP	Pointer to the field object ( <a href="#">FieldType</a> structure) to delete from.
	-> start	The beginning of the range of characters to delete given as a valid byte offset into the field's text string.
	-> end	The end of the range of characters to delete given as a valid byte offset into the field's text string. On systems that support multi-byte characters, this position must be an inter-character boundary. That is, it must not point to a middle byte of a multi-byte character.
<b>Result</b>	Returns nothing.	
<b>Comments</b>	<p>This function deletes all characters from the starting offset up to the ending offset and sets the field's dirty attribute. It does not delete the character at the ending offset.</p> <p>If <code>start</code> or <code>end</code> point to an intra-character boundary, <code>FldDelete</code> attempts to move the offset backward, toward the beginning of the text, until the offset points to an inter-character boundary (i.e., the start of a character).</p> <p><code>FldDelete</code> posts a <a href="#">fldChangedEvent</a> to the event queue. If you call this function repeatedly, you may overflow the event queue with <code>fldChangedEvents</code>. An alternative is to remove the text</p>	

## Fields

### Field Functions

---

handle from the field, change the text, and then set the field's handle again. See [FldGetTextHandle](#) for a code example.

**See Also** [FldInsert](#), [FldEraseField](#), [TxtCharBounds](#)

## FldDirty

**Purpose** Return true if the field has been modified since the text value was set.

**Declared In** `Field.h`

**Prototype** `Boolean FldDirty (const FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns true if the field has been modified either by the user or through calls to certain functions such as [FldInsert](#) and [FldDelete](#), false if the field has not been modified.

**See Also** [FldSetDirty](#), [FieldAttrType](#)

## FldDrawField

**Purpose** Draw the text of the field.

**Declared In** `Field.h`

**Prototype** `void FldDrawField (FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns nothing.

**Comments** The field's usable attribute must be true or the field won't be drawn.

This function doesn't erase the area behind the field before drawing.

If the field has the focus, the blinking insertion point is displayed in the field.

**See Also** [FldEraseField](#)

## **FldEraseField**

**Purpose** Erase the text of a field and turn off the insertion point if it's in the field.

**Declared In** `Field.h`

**Prototype** `void FldEraseField (FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns nothing.

**Comments** You rarely need to call this function directly. Instead, use [FrmHideObject](#), which calls `FldEraseField` for you.

This function visibly erases the field from the display, but it doesn't modify the contents of the field or free the memory associated with it.

If the field has the focus, the blinking insertion point is turned off.

This function sets the `visible` attribute to `false`. (See [FieldAttrType](#).)

**See Also** [FldDrawField](#)

## Fields

### Field Functions

---

## FldFreeMemory

- Purpose** Release the handle-based memory allocated to the field's text and the associated word-wrapping information.
- Declared In** `Field.h`
- Prototype** `void FldFreeMemory (FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns nothing. May raise a fatal error message if the text associated with the field is actually a record in a database.
- Comments** This function releases
- The memory allocated to the text of a field—the memory block that the `textHandle` member of the `FieldType` data structure points to.  
If the field's `textHandle` is `NULL` but there is a `text` string associated with that field (which is often the case with noneditable text fields), the text string is not freed.
  - The memory allocated to hold the word-wrapping information—the memory block that the `lines` member of the `FieldType` data structure points to.
- This function doesn't affect the display of the field. Fields allocate memory for the text string as needed, so it is not an error to call this function while the field is still displayed. That is, if `text` is `NULL` and the user starts typing in the field, the field simply allocates memory for text and continues.

## FldGetAttributes

- Purpose** Return the attributes of a field.
- Declared In** `Field.h`
- Prototype**  
`void FldGetAttributes (const FieldType *fldP,  
FieldAttrPtr attrP)`
- Parameters**
- |          |   |
|----------|---|
| -> fldP  | Pointer to a <a href="#">FieldType</a> structure.       |
| <- attrP | Pointer to the <a href="#">FieldAttrType</a> structure. |
- Result** Returns the field's attributes in the attrP parameter.
- See Also** [FldSetAttributes](#)

## FldGetBounds

- Purpose** Return the current bounds of a field.
- Declared In** `Field.h`
- Prototype**  
`void FldGetBounds (const FieldType *fldP,  
RectanglePtr rect)`
- Parameters**
- |         |   |
|---------|---|
| -> fldP | Pointer to a field object ( <a href="#">FieldType</a> structure). |
| <- rect | Pointer to a <a href="#">RectangleType</a> structure.             |
- Result** Returns nothing. Stores the field's bounds in the [RectangleType](#) structure reference by rect.
- Comments** Returns the rect field of the [FieldType](#) structure.
- See Also** [FldSetBounds](#), [FrmGetObjectBounds](#)

## Fields

### Field Functions

---

#### FldGetFont

- Purpose** Return the ID of the font used to draw the text of a field.
- Declared In** `Field.h`
- Prototype** `FontID FldGetFont (const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns the ID of the font.
- See Also** [FldSetFont](#)

#### FldGetInsPtPosition

- Purpose** Return the insertion point position within the string.
- Declared In** `Field.h`
- Prototype** `UInt16 FldGetInsPtPosition (const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns the byte offset of the insertion point.
- Comments** The insertion point is to the left of the byte offset that this function returns. That is, if this function returns 0, the insertion point is to the left of the first character in the string. In multiline fields, line feeds are counted as a single character in the string, and the byte offset after the line feed character is the beginning of the next line.
- See Also** [FldSetInsPtPosition](#)

## FldGetMaxChars

- Purpose** Return the maximum number of bytes the field accepts.
- Declared In** `Field.h`
- Prototype** `UInt16 FldGetMaxChars (const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns the maximum length in bytes of characters the user is allowed to enter. This is the `maxChars` field in `FieldType`.
- See Also** [FldSetMaxChars](#)

## FldGetNumberOfBlankLines

- Purpose** Return the number of blank lines that are displayed at the bottom of a field.
- Declared In** `Field.h`
- Prototype** `UInt16 FldGetNumberOfBlankLines (const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a [FieldType](#) structure.
- Result** Returns the number of blank lines visible.
- Comments** This routine is useful for updating a scroll bar after characters have been removed from the text in a field. See the `NoteViewScroll` function in the Address sample application for an example.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## Fields

### Field Functions

---

#### FldGetScrollPosition

- Purpose** Return the offset of the first character in the first visible line of a field.
- Declared In** `Field.h`
- Prototype**  
`UInt16 FldGetScrollPosition  
(const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns the offset of the first visible character.
- See Also** [FldSetScrollPosition](#), [LineInfoType](#)

#### FldGetScrollValues

- Purpose** Return the values necessary to update a scroll bar.
- Declared In** `Field.h`
- Prototype**  
`void FldGetScrollValues (const FieldType *fldP,  
UInt16 *scrollPosP, UInt16 *textHeightP,  
UInt16 *fieldHeightP)`
- Parameters**
- `-> fldP` Pointer to a [FieldType](#) structure.
  - `<- scrollPosP` The line of text that is the topmost visible line. Line numbering starts with 0.
  - `<-textHeightP` The number of lines needed to display the field's text, given the width of the field.
  - `<-fieldHeightP` The number of visible lines in the field.
- Result** Returns nothing. Stores the position, text height, and field height in the parameters passed in.

**Comments** Use the values returned by this function to calculate the values you send to [ScISetScrollBar](#) to update the scroll bar. For example:

```
FldGetScrollValues (fldP, &scrollPos,
                   &textHeight, &fieldHeight);

if (textHeight > fieldHeight)
    maxValue = textHeight - fieldHeight;
else if (scrollPos)
    maxValue = scrollPos;
else
    maxValue = 0;

ScISetScrollBar (bar, scrollPos, 0, maxValue,
                fieldHeight-1);
}
```

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [FldSetScrollPosition](#)

## FldGetSelection

**Purpose** Return the current selection of a field.

**Declared In** Field.h

**Prototype** void FldGetSelection (const FieldType \*fldP,  
UInt16 \*startPosition, UInt16 \*endPosition)

**Parameters** -> fldP                    Pointer to a field object ([FieldType](#) structure).

<- startPosition  
                                  Pointer to the start of the selected characters  
                                  range, given as the byte offset into the field's  
                                  text.

## Fields

### Field Functions

---

`<- endPosition` Pointer to end of the selected characters range given as the byte offset into the field's text.

**Result** Returns the starting and ending byte offsets in `startPosition` and `endPosition`.

**Comments** The first character in a field is at offset zero. If the user has selected the first five characters of a field, `startPosition` will contain the value 0 and `endPosition` the value 5, assuming all characters are a single byte long.

**See Also** [FldSetSelection](#)

## FldGetTextAllocatedSize

**Purpose** Return the number of bytes allocated to hold the field's text string. Don't confuse this number with the actual length of the text string displayed in the field.

**Declared In** `Field.h`

**Prototype** `UInt16 FldGetTextAllocatedSize  
(const FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object.

**Result** Returns the number of bytes allocated for the field's text. This is the `textBlockSize` field in [FieldType](#).

**See Also** [FldSetTextAllocatedSize](#)

## FldGetTextHandle

- Purpose** Return a handle to the block that contains the text string of a field.
- Declared In** `Field.h`
- Prototype** `MemHandle FldGetTextHandle  
(const FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns the handle to the text string of a field or NULL if no handle has been allocated for the field pointer.
- Comments** The handle returned by this function is not necessarily the handle to the start of the string. If you've used [FldSetText](#) to set the field's text to a string that is part of a database record, the text handle points to the start of that record. You'll need to compute the offset from the start of the record to the start of the string. You can either store the offset that you passed to [FldSetText](#) or you can compute the offset by performing pointer arithmetic on the pointer you get by locking this handle and the pointer returned by [FldGetTextPtr](#).
- If you are obtaining the text handle so that you can edit the field's text, you must remove the handle from the field before you do so. If you change the text while it is being used by a field, the field's internal structures specifying the text length, allocated size, and word wrapping information can become out of sync. To avoid this problem, remove the text handle from the field, change the text, and then set the field's text handle again. For example:
- ```
/* Get the handle for the string and unlock */  
/* it by removing it from the field. */  
textH = FldGetTextHandle(fldP);  
FldSetTextHandle (fldP, NULL);  
  
/* Insert code that modifies the string here.*/  
/* The basic steps are: */  
/* resize the chunk if necessary,*/
```

## Fields

### Field Functions

---

```
/* lock the chunk, write to it, and then */
/* unlock the chunk. If the text is in a */
/* database record, use Data Manager calls. */

/* Update the text in the field. */
FldSetTextHandle (fldP, textH);
FldDrawField(fldP);
```

**See Also** [FldSetTextHandle](#), [FldGetTextPtr](#)

## FldGetTextHeight

**Purpose** Return the height in pixels of the number of visible lines that are not empty.

**Declared In** Field.h

**Prototype** UInt16 FldGetTextHeight (const FieldType \*fldP)

**Parameters** -> fldP                    Pointer to a field object ([FieldType](#) structure).

**Result** Returns the height in pixels of the number of visible lines that are not empty.

**Comments** Empty lines are all of the lines in the field following the last byte of text. Note that lines that contain only a linefeed are not empty. Also note that only lines that are visible are counted.

**See Also** [FldCalcFieldHeight](#)

## FldGetTextLength

|                    |                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the length in bytes of the field's text.                                                                                                                 |
| <b>Declared In</b> | <code>Field.h</code>                                                                                                                                            |
| <b>Prototype</b>   | <code>UInt16 FldGetTextLength (const FieldType *fldP)</code>                                                                                                    |
| <b>Parameters</b>  | -> <code>fldP</code> Pointer to a field object ( <a href="#">FieldType</a> structure).                                                                          |
| <b>Result</b>      | Returns the length in bytes of a field's text, not including the terminating null character. This is the <code>textLen</code> field of <code>FieldType</code> . |

## FldGetTextPtr

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return a locked pointer to the field's text string.                                                               |
| <b>Declared In</b> | <code>Field.h</code>                                                                                              |
| <b>Prototype</b>   | <code>Char *FldGetTextPtr (const FieldType *fldP)</code>                                                          |
| <b>Parameters</b>  | -> <code>fldP</code> Pointer to a field object ( <a href="#">FieldType</a> structure).                            |
| <b>Result</b>      | Returns a locked pointer to the field's text string or NULL if the field is empty.                                |
| <b>Comments</b>    | The pointer returned by this function can become invalid if the user edits the text after you obtain the pointer. |

Do not modify the contents of the pointer yourself. If you change the text while it is being used by a field, the field's internal structures specifying the text length, allocated size, and word wrapping information can become out of sync. To avoid this problem, follow the instructions given under [FldGetTextHandle](#).

## Fields

### Field Functions

---

---

**WARNING!** The pointer returned by this function is “owned” by the field until you specify a different pointer for the field. You should not store this pointer for future use, since the field can modify the size of the string, which can cause the pointer to become invalid.

---

**See Also** [FldSetTextPtr](#), [FldGetTextHandle](#)

## FldGetVisibleLines

**Purpose** Return the number of lines that can be displayed within the visible bounds of the field, regardless of what text is stored in the field.

**Declared In** `Field.h`

**Prototype** `UInt16 FldGetVisibleLines (const FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns the number of lines the field displays. (This is the size of the lines array in the `FieldType` structure.)

**See Also** [FldGetNumberOfBlankLines](#), [FldCalcFieldHeight](#)

## FldGrabFocus

**Purpose** Turn the insertion point on (if the specified field is visible) and position the blinking insertion point in the field.

**Declared In** `Field.h`

**Prototype** `void FldGrabFocus (FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns nothing.

**Comments** You rarely need to call this function directly. Instead, use [FrmSetFocus](#), which calls `FldGrabFocus` for you.

One instance where you need to call `FldGrabFocus` directly is to programmatically set the focus in a field that is contained in a table cell.

This function sets the field attribute `hasFocus` to `true`. (See [FieldAttrType](#).)

**See Also** [FrmSetFocus](#), [FldReleaseFocus](#)

## FldHandleEvent

**Purpose** Handles events that affect the field, including the following: [keyDownEvent](#), [penDownEvent](#), and [fldEnterEvent](#).

**Declared In** `Field.h`

**Prototype** `Boolean FldHandleEvent (FieldType *fldP, EventType *eventP)`

**Parameters**

|                           |                                                                   |
|---------------------------|-------------------------------------------------------------------|
| <code>-&gt; fldP</code>   | Pointer to a field object ( <a href="#">FieldType</a> structure). |
| <code>-&gt; eventP</code> | Pointer to an event ( <code>EventType</code> data structure).     |

**Result** Returns `true` if the event was handled.

**Comments** When a [keyDownEvent](#) occurs in an editable text field, the keystroke appears in the field if it's a printable character or manipulates the insertion point if it's a "movement" character. The field is automatically updated.

When a [penDownEvent](#) occurs, the field sends a [fldEnterEvent](#) to the event queue.

When a [fldEnterEvent](#) occurs, the field grabs the focus. If the user has tapped twice in the current location, the word at that location is selected. If the user has tapped three times, the entire line is selected. Otherwise, the insertion point is placed in the specified position.

## Fields

### Field Functions

---

When a [menuCmdBarOpenEvent](#) occurs, the field adds paste, copy, cut, and undo buttons to the command toolbar. These buttons are only added if they make sense in the current context. That is, the cut button is only added if the field is editable, the paste button is only added if there is text on the clipboard and the field is editable, and the undo button is only added if there is an action to undo.

If the event alters the contents of the field, this function visually updates the field.

This function doesn't handle any events if the field is not editable or usable.

**Compatibility** Double-tapping to select a word and triple-tapping to select a line are only supported if [3.5 New Feature Set](#) is present.

`FldHandleEvent` only handles the `menuCmdBarOpenEvent` if [3.5 New Feature Set](#) is present.

## FldInsert

**Purpose** Replace the current selection if any with the specified string and redraw the field.

**Declared In** `Field.h`

**Prototype** `Boolean FldInsert (FieldType *fldP,  
const Char *insertChars, UInt16 insertLen)`

**Parameters**

- > `fldP` Pointer to the field object ([FieldType](#) structure) to insert to.
- > `insertChars` Text string to be inserted.
- > `insertLen` Length in bytes of the text string to be inserted, not counting the trailing null character.

**Result** Returns `true` if string was successfully inserted. Returns `false` if:

- The `insertLen` parameter is 0.
- The field is not editable.

- Adding the text would exceed the field's size limit (the `maxChars` value).
- More memory must be allocated for the field, and the allocation fails.

**Comments** If there is no current selection, the string passed is inserted at the position of the insertion point.

This function sets the field's dirty attribute and posts a [fldChangedEvent](#) to the event queue. If you call this function repeatedly, you may overflow the event queue with `fldChangedEvents`. An alternative is to remove the text handle from the field, change the text, and then set the field's handle again. See [FldGetTextHandle](#) for a code example.

**See Also** [FldPaste](#), [FldDelete](#), [FldCut](#), [FldCopy](#)

## **FldMakeFullyVisible**

**Purpose** Generates an event to cause a dynamically resizable field to expand its height to make its text fully visible.

**Declared In** `Field.h`

**Prototype** `Boolean FldMakeFullyVisible (FieldType *fldP)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns `true` if the field is dynamically resizable and was not fully visible; `false` otherwise.

**Comments** Use this function on a field whose `dynamicSize` attribute is `true` (see [FieldAttrType](#)).

This function does not actually resize the field. Instead, it computes how big the field should be to be fully visible and then posts this information to the event queue in a [fldHeightChangedEvent](#).

## Fields

### Field Functions

---

---

**NOTE:** The event does not get generated if the number of lines in the field is equal to or greater than the value of the maximum lines attribute for the field.

---

If the field is contained in a table, the table's code handles the `fldHeightChangedEvent`. If the field is directly on a form, your application code should handle the `fldHeightChangedEvent` itself. The form code does not handle the event for you. Note that the constant `maxFieldLines` defines the maximum number of lines a field can expand to if the field is using the standard font.

**See Also** [TblHandleEvent](#)

## FldNewField

**Purpose** Create a new field object dynamically and install it in the specified form.

**Declared In** `Field.h`

**Prototype** `FieldType *FldNewField (void **formPP, UInt16 id, Coord x, Coord y, Coord width, Coord height, FontID font, UInt32 maxChars, Boolean editable, Boolean underlined, Boolean singleLine, Boolean dynamicSize, JustificationType justification, Boolean autoShift, Boolean hasScrollBar, Boolean numeric)`

**Parameters** `<-> formPP` Pointer to the pointer to the form in which the new field is installed. This value is not a handle; that is, the old form pointer value is not necessarily valid after this function returns. In subsequent calls, always use the new form pointer value returned by this function.

|                               |                                                                                                                                                                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>id</code>            | Symbolic ID of the field, specified by the developer. By convention, this ID should match the resource ID (not mandatory).                                                                                                                                               |
| -> <code>x</code>             | Horizontal coordinate of the upper-left corner of the field's boundaries, relative to the window in which it appears.                                                                                                                                                    |
| -> <code>y</code>             | Vertical coordinate of the upper-left corner of the field's boundaries, relative to the window in which it appears.                                                                                                                                                      |
| -> <code>width</code>         | Width of the field, expressed in pixels.                                                                                                                                                                                                                                 |
| -> <code>height</code>        | Height of the field, expressed in pixels.                                                                                                                                                                                                                                |
| -> <code>font</code>          | Font to use to draw the field's text.                                                                                                                                                                                                                                    |
| -> <code>maxChars</code>      | Maximum number of bytes held by the field this function creates.                                                                                                                                                                                                         |
| -> <code>editable</code>      | Pass <code>true</code> to create a field in which the user can edit text. Pass <code>false</code> to create a field that cannot be edited.                                                                                                                               |
| -> <code>underlined</code>    | Pass <code>noUnderline</code> for no underline, or <code>grayUnderline</code> to have the field underline the text it displays. On Palm OS <sup>®</sup> version 3.1 and higher, pass <code>solidUnderline</code> to use a solid underline instead of a dotted underline. |
| -> <code>singleLine</code>    | Pass <code>true</code> to create a field that can display only a single line of text.                                                                                                                                                                                    |
| -> <code>dynamicSize</code>   | Pass <code>true</code> to create a field that resizes dynamically according to the amount of text it displays.                                                                                                                                                           |
| -> <code>justification</code> | Pass either of the values <code>leftAlign</code> or <code>rightAlign</code> to specify left justification or right justification, respectively. The <code>centerAlign</code> value is not supported.                                                                     |
| -> <code>autoShift</code>     | Pass <code>true</code> to specify the use of Palm OS 2.0 (and later) auto-shift rules.                                                                                                                                                                                   |

## Fields

### Field Functions

---

- > `hasScrollBar` Pass `true` to attach a scroll bar control to the field this function creates.
- > `numeric` Pass `true` to specify that only characters in the range of 0 through 9 are allowed in the field.

**Result** Returns a pointer to the new field object or `NULL` if there wasn't enough memory to create the field. Out of memory situations could be caused by memory fragmentation.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FrmValidatePtr](#), [WinValidateHandle](#), [CtlValidatePointer](#), [FrmRemoveObject](#)

## FldPaste

**Purpose** Replace the current selection in the field, if any, with the contents of the text clipboard.

**Declared In** `Field.h`

**Prototype** `void FldPaste (FieldType *fldP)`

**Parameters** -> `fldP` Pointer to a field object ([FieldType](#) structure).

**Result** Returns nothing

**Comments** The function performs these actions:

- Scrolls the field, if necessary, so the insertion point is visible.
- Inserts the clipboard text at the position of the insertion point if there is no current selection.
- Positions the insertion point after the last character inserted.
- Doesn't delete the current selection if there is no text in the clipboard.

**See Also** [FldInsert](#), [FldDelete](#), [FldCut](#), [FldCopy](#), [FldUndo](#)

## FldRecalculateField

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |         |                                                                   |           |                             |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------------------------------------------------------------|-----------|-----------------------------|
| <b>Purpose</b>       | Update the structure that contains the word-wrapping information for each visible line.                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |                                                                   |           |                             |
| <b>Declared In</b>   | Field.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |         |                                                                   |           |                             |
| <b>Prototype</b>     | <pre>void FldRecalculateField (FieldType *fldP,<br/>Boolean redraw)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |         |                                                                   |           |                             |
| <b>Parameters</b>    | <table><tr><td>-&gt; fldP</td><td>Pointer to a field object (<a href="#">FieldType</a> structure).</td></tr><tr><td>-&gt; redraw</td><td>If true, redraws the field.</td></tr></table>                                                                                                                                                                                                                                                                                                                                       | -> fldP | Pointer to a field object ( <a href="#">FieldType</a> structure). | -> redraw | If true, redraws the field. |
| -> fldP              | Pointer to a field object ( <a href="#">FieldType</a> structure).                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |                                                                   |           |                             |
| -> redraw            | If true, redraws the field.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |         |                                                                   |           |                             |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |         |                                                                   |           |                             |
| <b>Comments</b>      | <p>This function will allocate the memory block that contains the displayed lines information if, and only if, the block does not yet exist.</p> <p>You should call this function when you change the field width or text length of the field. Do not call this function after changing the font or field height.</p> <p>Note that many of the field functions, including <a href="#">FldSetTextHandle</a>, <a href="#">FldInsert</a>, and <a href="#">FldDelete</a>, recalculate the word-wrapping information for you.</p> |         |                                                                   |           |                             |
| <b>Compatibility</b> | In releases prior to Palm OS 4.0, the word-wrapping information is only updated if the <code>redraw</code> parameter is set to <code>true</code> . As of Palm OS 4.0 it is updated whenever <code>FldRecalculateField</code> is called, regardless of the value of the <code>redraw</code> parameter.                                                                                                                                                                                                                        |         |                                                                   |           |                             |

## Fields

### Field Functions

---

#### FldReleaseFocus

- Purpose** Turn the blinking insertion point off if the field is visible and has the current focus, reset the Graffiti state, and reset the undo state.
- Declared In** `Field.h`
- Prototype** `void FldReleaseFocus (FieldType *fldP)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).
- Result** Returns nothing.
- Comments** This function sets the field attribute `hasFocus` to `false`. (See [FieldAttrType](#).)
- Usually, you don't need to call this function. If the field is in a form or in a table that doesn't use custom drawing functions, the field code releases the focus for you when the focus changes to some other control. If your field is in any other type of object, such as a table that uses custom drawing functions or a gadget, you must call `FldReleaseFocus` when the focus moves away from the field.
- See Also** [FldGrabFocus](#)

#### FldScrollable

- Purpose** Return `true` if the field is scrollable in the specified direction.
- Declared In** `Field.h`
- Prototype** `Boolean FldScrollable (const FieldType *fldP, WinDirectionType direction)`
- Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).

-> direction      The direction to test. `DirectionType` is defined in `Window.h`. It is an enum defining the constants up and down.

**Result**      Returns `true` if the field is scrollable in the specified direction; `false` otherwise.

**See Also**      [FldScrollField](#)

## **FldScrollField**

**Purpose**      Scroll a field up or down by the number of lines specified.

**Declared In**      `Field.h`

**Prototype**      `void FldScrollField (FieldType *fldP,  
                          UInt16 linesToScroll, WinDirectionType direction)`

**Parameters**      -> `fldP`              Pointer to a field object ([FieldType](#) structure).  
                     -> `linesToScroll`      Number of lines to scroll.  
                     -> `direction`          The direction to scroll. `DirectionType` is defined in `Window.h`. It is an enum defining, among others, the constants `winUp` and `winDown`.

**Result**      Returns nothing.

**Comments**      This function can't scroll horizontally, that is, right or left.  
                     The field object is redrawn if it's scrolled; however, the scrollbar is not updated. Use [SclSetScrollBar](#) to update the scrollbar. For example:

```
FldScrollField (fldP, linesToScroll,  
                  direction);  
  
// Update the scroll bar.  
SclGetScrollBar (bar, &value, &min, &max,
```

## Fields

### Field Functions

---

```
        &pageSize);

    if (direction == winUp)
        value -= linesToScroll;
    else
        value += linesToScroll;

    Sc1SetScrollBar (bar, value, min, max,
                    pageSize);
```

If the field is not scrollable in the direction indicated, this function returns without performing any work. You can use [FldScrollable](#) before calling this function to see if the field can be scrolled.

**See Also** [FldScrollable](#), [FldSetScrollPosition](#)

## FldSendChangeNotification

**Purpose** Send a [fldChangedEvent](#) to the event queue.

**Declared In** Field.h

**Prototype** void FldSendChangeNotification  
(const FieldType \*fldP)

**Parameters** -> fldP                      Pointer to a field object.

**Result** Returns nothing.

**Comments** This function is used internally by the field code. You normally never call it in application code.

## FldSendHeightChangeNotification

- Purpose** Send a [fldHeightChangedEvent](#) to the event queue.
- Declared In** Field.h
- Prototype**  
`void FldSendHeightChangeNotification  
(const FieldType *fldP, UInt16 pos,  
Int16 numLines)`
- Parameters**
- > fldP                    Pointer to a field object.
  - > pos                    Character position of the insertion point.
  - > numLines              New number of lines in the field.
- Result** Returns nothing.
- Comments** This function is used internally by the field code. You normally never call it in application code.

## FldSetAttributes

- Purpose** Set the attributes of a field.
- Declared In** Field.h
- Prototype**  
`void FldSetAttributes (FieldType *fldP,  
const FieldAttrType *attrP)`
- Parameters**
- > fldP                    Pointer to a [FieldType](#) structure.
  - > attrP                  Pointer to the attributes.
- Result** Returns nothing.
- Comments** This function does not do anything to make the new attribute values take effect. For example, if you use this function to change the value of the underline attribute, you won't see its effect until you call [FldDrawField](#).

## Fields

### Field Functions

---

You usually do not have to modify field attributes at runtime, so you rarely need to call this function.

---

**WARNING!** You must not call this function to change any attributes that are noted as “for internal use only.”

---

The proper way to use `FldSetAttributes` is to:

1. Call `FldGetAttributes` to retrieve the attributes.
2. Set the specific flags that you want to modify.
3. Call `FldSetAttributes` to make the modifications.

---

**WARNING!** You must not call any field routines between calling `FldGetAttributes` and `FldSetAttributes`; this can cause the attributes to be out of sync, with unpredictable results.

---

**See Also** [FldGetAttributes](#), [FieldAttrType](#)

## FldSetBounds

|                      |                                                                                                                                                                                                                                                                                 |                      |                                                                   |                    |                                                                                                |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|-------------------------------------------------------------------|--------------------|------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Change the position or size of a field.                                                                                                                                                                                                                                         |                      |                                                                   |                    |                                                                                                |
| <b>Declared In</b>   | <code>Field.h</code>                                                                                                                                                                                                                                                            |                      |                                                                   |                    |                                                                                                |
| <b>Prototype</b>     | <pre>void FldSetBounds (FieldType *fldP,<br/>const RectangleType *rP)</pre>                                                                                                                                                                                                     |                      |                                                                   |                    |                                                                                                |
| <b>Parameters</b>    | <table><tr><td>-&gt; <code>fldP</code></td><td>Pointer to a field object (<a href="#">FieldType</a> structure).</td></tr><tr><td>-&gt; <code>rP</code></td><td>Pointer to a <code>RectangleType</code> structure that contains the new bounds of the display.</td></tr></table> | -> <code>fldP</code> | Pointer to a field object ( <a href="#">FieldType</a> structure). | -> <code>rP</code> | Pointer to a <code>RectangleType</code> structure that contains the new bounds of the display. |
| -> <code>fldP</code> | Pointer to a field object ( <a href="#">FieldType</a> structure).                                                                                                                                                                                                               |                      |                                                                   |                    |                                                                                                |
| -> <code>rP</code>   | Pointer to a <code>RectangleType</code> structure that contains the new bounds of the display.                                                                                                                                                                                  |                      |                                                                   |                    |                                                                                                |
| <b>Result</b>        | Returns nothing. May raise a fatal error message if the memory block that contains the word-wrapping information needs to be resized and there is not enough space to do so.                                                                                                    |                      |                                                                   |                    |                                                                                                |
| <b>Comments</b>      | If the field is visible, the field is redrawn within its new bounds.                                                                                                                                                                                                            |                      |                                                                   |                    |                                                                                                |

---

**NOTE:** You can change the height or location of the field while it's visible, but do not change the width.

---

## Fields

### Field Functions

---

The memory block that contains the word-wrapping information (see [LineInfoType](#)) will be resized if the number of visible lines is changed. The insertion point is assumed to be off when this routine is called.

Make sure that `rect` is at least as tall as a single line in the current font. (You can determine this value by calling [FntLineHeight](#).) If it's not, results are unpredictable.

**See Also** [FldGetBounds](#), [FrmSetObjectBounds](#)

## FldSetDirty

**Purpose** Set whether the field has been modified.

**Declared In** `Field.h`

**Prototype** `void FldSetDirty (FieldType *fldP, Boolean dirty)`

**Parameters**

|                       |                                                                   |
|-----------------------|-------------------------------------------------------------------|
| -> <code>fldP</code>  | Pointer to a field object ( <a href="#">FieldType</a> structure). |
| -> <code>dirty</code> | true if the text is modified.                                     |

**Result** Returns nothing.

**Comments** You typically call this function when you want to clear the dirty attribute. The dirty attribute is set when the user enters or deletes text in the field. It is also set by certain field functions, such as [FldInsert](#) and [FldDelete](#).

**See Also** [FldDirty](#)

## FldSetFont

- Purpose** Set the font used by the field, update the word-wrapping information, and draw the field if the field is visible.
- Declared In** `Field.h`
- Prototype** `void FldSetFont (FieldType *fldP, FontID fontID)`
- Parameters**
- > `fldP` Pointer to a field object ([FieldType](#) structure).
  - > `fontID` ID of new font.
- Result** Returns nothing.
- See Also** [FldGetFont](#), [FieldAttrType](#)

## FldSetInsertionPoint

- Purpose** Set the location of the insertion point based on a specified string position.
- Declared In** `Field.h`
- Prototype** `void FldSetInsertionPoint (FieldType *fldP, UInt16 pos)`
- Parameters**
- > `fldP` Pointer to a [FieldType](#) structure.
  - > `pos` New location of the insertion point, given as a valid offset in bytes into the field's text. On systems that support multi-byte characters, you must make sure that this specifies an inter-character boundary (does not specify the middle or end bytes of a multi-byte character).
- Result** Nothing.

## Fields

### Field Functions

---

**Comments** This routine differs from [FldSetInsPtPosition](#) in that it doesn't make the character position visible. `FldSetInsertionPoint` also doesn't make the field the current focus of input if it was not already.

If `pos` indicates a position beyond the end of the text in the field, the insertion point is set to the end of the field's text.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [TxtCharBounds](#)

## FldSetInsPtPosition

**Purpose** Set the location of the insertion point for a given string position.

**Declared In** `Field.h`

**Prototype**

```
void FldSetInsPtPosition (FieldType *fldP,  
                          UInt16 pos)
```

**Parameters**

|                      |                                                                                                                                                                                                                                                                                      |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>fldP</code> | Pointer to a field object ( <a href="#">FieldType</a> structure).                                                                                                                                                                                                                    |
| -> <code>pos</code>  | New location of the insertion point, given as a valid offset in bytes into the field's text. On systems that support multi-byte characters, you must make sure that this specifies an inter-character boundary (does not specify the middle or end bytes of a multi-byte character). |

**Result** Returns nothing.

**Comments** If the position is beyond the visible text, the field is scrolled until the position is visible.

**See Also** [FldGetInsPtPosition](#), [TxtCharBounds](#)

## FldSetMaxChars

- Purpose** Set the maximum number of bytes the field accepts (the maxChars value).
- Declared In** `Field.h`
- Prototype** `void FldSetMaxChars (FieldType *fldP,  
UInt16 maxChars)`
- Parameters**
- |             |                                                                                                              |
|-------------|--------------------------------------------------------------------------------------------------------------|
| -> fldP     | Pointer to a field object ( <a href="#">FieldType</a> structure).                                            |
| -> maxChars | Maximum size in bytes of the characters the user may enter. You may specify any value up to maxFieldTextLen. |
- Result** Returns nothing.
- Comments** Line feed characters are counted when the length of characters is determined.
- See Also** [FldGetMaxChars](#)

## FldSetMaxVisibleLines

- Purpose** Allows the creation of tables and fields smaller than 121 pixels tall that still drag-select when there are more lines of text than will fit in the space provided.
- Declared In** `Field.h`
- Prototype** `void FldSetMaxVisibleLines (FieldType *fldP,  
UInt8 maxLines)`
- Parameters**
- |         |                                                                   |
|---------|-------------------------------------------------------------------|
| -> fldP | Pointer to a field object ( <a href="#">FieldType</a> structure). |
|---------|-------------------------------------------------------------------|

To do so, first call [FldGetScrollValues](#) to determine the values to use, and then call [SclSetScrollBar](#).

**See Also** [FldGetScrollPosition](#), [FldScrollField](#), [TxtCharBounds](#)

## **FldSetSelection**

**Purpose** Set the current selection in a field and highlight the selection if the field is visible.

**Declared In** `Field.h`

**Prototype** `void FldSetSelection (FieldType *fldP,  
UInt16 startPosition, UInt16 endPosition)`

**Parameters**

- > `fldP` Pointer to a field object ([FieldType](#) structure).
- > `startPosition` Starting offset of the character range to highlight, given as a byte offset into the field's text.
- > `endPosition` Ending offset of the character range to highlight. The ending offset should be greater than or equal to the starting offset. On systems that support multi-byte characters, this position must be an inter-character boundary. That is, it must not point to a middle byte of a multi-byte character.

**Result** Returns nothing.

**Comments** To cancel a selection, set both `startPosition` and `endPosition` to the same value. If `startPosition` equals `endPosition`, then the current selection is unhighlighted.

If either `startPosition` or `endPosition` point to an intra-character boundary, `FldSetSelection` attempts to move that

## Fields

### Field Functions

---

offset backward, toward the beginning of the string, until the offset points to an inter-character boundary (i.e., the start of a character).

**See Also** [TxtCharBounds](#)

## FldSetText

**Purpose** Set the text value of the field without updating the display.

**Declared In** `Field.h`

**Prototype** `void FldSetText (FieldType *fldP,  
MemHandle textHandle, UInt16 offset, UInt16 size)`

**Parameters**

|               |                                                                                                                                                                                                                                                                  |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> fldP       | Pointer to a field object ( <a href="#">FieldType</a> structure).                                                                                                                                                                                                |
| -> textHandle | Unlocked handle of a block containing a null-terminated text string. Pass NULL for this parameter to remove the association between the field and the string it is currently displaying so that the string is not freed with the field when the form is deleted. |
| -> offset     | Offset from start of block to start of the text string.                                                                                                                                                                                                          |
| -> size       | The allocated size of the text string. This is not the string length, and should not be set to 0, unless you are setting the text to the empty string.                                                                                                           |

**Result** Returns nothing.

**Comments** This function allows applications to perform editing in place in memory. You can use it to point the field to a string in a database record so that you can edit that string directly using field routines.

As characters are added to the field's text, the block that contains the text is grown. So that the block doesn't have to be expanded for each character, it is expanded several bytes at a time; this expansion may result in some unused space in the text block. As characters are

removed from the field's text, the space is not automatically reclaimed. Because adding or removing characters when editing a data record in place may result in unused space at the end of the field's text block, applications should call [FldCompactText](#) on before the field is unlocked to release any unused space.

The handle that you pass to this function is assumed to contain a null-terminated string starting at `offset` bytes in the memory chunk. The string should be between 0 and `size - 1` bytes in length. The field does not make a copy of the memory chunk or the string data; instead, it stores the handle to the record in its structure.

---

**WARNING!** You cannot use this function to set two fields on a form so that they share a single string value. Thus, for instance, if you have a single string containing a person's name you cannot call `FldSetText` twice with the same string (but a different offset) to set up a first name field and a last name field.

---

`FldSetText` updates the word-wrapping information and places the insertion point after the last visible character, but it does not update the display. You must call [FldDrawField](#) after calling this function to update the display.

`FldSetText` increments the lock count for `textHandle` and decrements the lock count of its previous text handle (if any).

Because `FldSetText` (and `FldSetTextHandle`) may be used to edit database records, they do not free the memory associated with the previous text handle. If the previous text handle points to a string on the dynamic heap and you want to free it, use [FldGetTextHandle](#) to obtain the handle before using `FldSetText` and then free that handle after using `FldSetText`. (See [FldSetTextHandle](#) for a code example.)

If the field points to a database record, you want the memory associated with the text handle to persist; however, this memory and all other memory associated with the field is freed when the field itself is freed, which happens when the form is closed. If you don't want the memory associated with the text handle freed when the field is freed, use `FldSetText` and pass `NULL` for the text handle immediately before the form is closed. Passing `NULL`

## Fields

### Field Functions

---

removes the association between the field and the text handle that you want retained. That text handle is unlocked as a result of the `FldSetText` call, and when the field is freed, there is no text handle to free with it.

**See Also** [FldSetTextPtr](#), [FldSetTextHandle](#)

## FldSetTextAllocatedSize

**Purpose** Set the number of bytes allocated to hold the field's text string. Don't confuse this with the actual length of the text string displayed in the field.

**Declared In** `Field.h`

**Prototype** `void FldSetTextAllocatedSize (FieldType *fldP, UInt16 allocatedSize)`

**Parameters** `-> fldP` Pointer to a field object ([FieldType](#) structure).  
`-> allocatedSize` Number of bytes to allocate for the text.

**Result** Returns nothing.

**Comments** This function generally is not used. It does not resize the field's allocated memory for the text string; it merely sets the `textBlockSize` field of the `FieldType` structure. The value of this field is computed and maintained internally by the field, so you should not have to call `FldSetTextAllocatedSize` directly.

**See Also** [FldGetTextAllocatedSize](#), [FldCompactText](#)

## FldSetTextHandle

- Purpose** Set the text value of a field to the string associated with the specified handle. Does not update the display.
- Declared In** `Field.h`
- Prototype** `void FldSetTextHandle (FieldType *fldP,  
MemHandle textHandle)`
- Parameters**
- > `fldP` Pointer to a field object ([FieldType](#) structure).
  - > `textHandle` Unlocked handle of a field's text string. Pass NULL for this parameter to remove the association between the field and the string it is currently displaying so that the string is not freed with the field when the form is deleted.
- Result** Returns nothing.
- Comments** This function differs from [FldSetText](#) in that it uses the entire memory chunk pointed to by `textHandle` for the string. In fact, this function simply calls `FldSetText` with an offset of 0 and a size equal to the entire length of the memory chunk. Use it to have the field edit a string in a database record if the entire record consists of that string, or use it to have the field edit a string in the dynamic heap.
- As characters are added to the field's text, the block that contains the text is grown. So that the block doesn't have to be expanded for each character, it is expanded several bytes at a time; this expansion may result in some unused space in the text block. As characters are removed from the field's text, the space is not automatically reclaimed. Because adding or removing characters when editing a data record in place may result in unused space at the end of the field's text block, applications should call [FldCompactText](#) on before the field is unlocked to release any unused space.
- `FldSetTextHandle` updates the word-wrapping information and places the insertion point after the last visible character, but it does

### Field Functions

---

not update the display. You must call [FldDrawField](#) after calling this function to update the display.

`FldSetTextHandle` increments the lock count for `textHandle` and decrements the lock count of its previous text handle (if any).

Because `FldSetTextHandle` (and `FldSetText`) may be used to edit database records, they do not free the memory associated with the previous text handle. If the previous text handle points to a string on the dynamic heap and you want to free it, use [FldGetTextHandle](#) to obtain the handle before using `FldSetText` and then free that handle after using `FldSetText`. For example:

```
/* get the old text handle */
oldTxtH = FldGetTextHandle(fldP);

/* change the text and update the display */
FldSetTextHandle(fldP, txtH);
FldDrawField(fldP);

/* free the old text handle */
if (oldTxtH != NULL)
    MemHandleFree(oldTxtH);
```

If the field points to a database record, you want the memory associated with the text handle to persist; however, this memory and all other memory associated with the field is freed when the field itself is freed, which happens when the form is closed. If you don't want the memory associated with the text handle freed when the field is freed, use `FldSetTextHandle` and pass `NULL` for the text handle immediately before the form is closed. Passing `NULL` removes the association between the field and the text handle that you want retained. That text handle is unlocked as a result of the `FldSetTextHandle` call, and when the field is freed, there is no text handle to free with it.

**See Also** [FldSetTextPtr](#), [FldSetText](#)

## FldSetTextPtr

- Purpose** Set a noneditable field's text to point to the specified text string.
- Declared In** `Field.h`
- Prototype** `void FldSetTextPtr (FieldType *fldP, Char *textP)`
- Parameters**
- > `fldP` Pointer to a field object ([FieldType](#) structure).
  - > `textP` Pointer to a null-terminated string.
- Result** Returns nothing. May display an error message if passed an editable text field.
- Comments** Do not call `FldSetTextPtr` with an editable text field. Instead, call [FldSetTextHandle](#) for editable text fields. `FldSetTextPtr` is intended for displaying noneditable text in the user interface.
- If the field has more than one line, use [FldRecalculateField](#) to recalculate the word wrapping.
- This function does **not** visually update the field. Use [FldDrawField](#) to do so.
- The field never frees the string that you pass to this function, even when the field itself is freed. You must free the string yourself. Before you free the string, make sure the field is not still displaying it. Set the field's string pointer to some other string or call `FldSetTextPtr(fldP, NULL)` before freeing a string you have passed using this function.

| <b>Parameters</b>  | <table><tr><td>fldP</td><td>Pointer to a <a href="#">FieldType</a> structure.</td></tr><tr><td>usable</td><td>true to set usable; false to set nonusable.</td></tr></table> | fldP | Pointer to a <a href="#">FieldType</a> structure. | usable | true to set usable; false to set nonusable. |
| fldP               | Pointer to a <a href="#">FieldType</a> structure.                                                                                                                           |      |                                                   |        |                                             |
| usable             | true to set usable; false to set nonusable.                                                                                                                                 |      |                                                   |        |                                             |
| <b>Result</b>      | Returns nothing.                                                                                                                                                            |      |                                                   |        |                                             |
| <b>Comments</b>    | A nonusable field doesn't display or accept input.<br>Use <a href="#">FrmHideObject</a> and <a href="#">FrmShowObject</a> instead of using this function.                   |      |                                                   |        |                                             |
| <b>See Also</b>    | <a href="#">FldEraseField</a> , <a href="#">FldDrawField</a> , <a href="#">FieldAttrType</a>                                                                                |      |                                                   |        |                                             |

#### FldUndo

|                    |                                                                                                                              |      |                                                                                 |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|------|---------------------------------------------------------------------------------|
| <b>Purpose</b>     | Undo the last change made to the field object, if any. Changes include typing, backspaces, delete, paste, and cut.           |      |                                                                                 |
| <b>Declared In</b> | Field.h                                                                                                                      |      |                                                                                 |
| <b>Prototype</b>   | <pre>void FldUndo (FieldType *fldP)</pre>                                                                                    |      |                                                                                 |
| <b>Parameters</b>  | <table><tr><td>fldP</td><td>Pointer to the field (<a href="#">FieldType</a> structure) that has the focus.</td></tr></table> | fldP | Pointer to the field ( <a href="#">FieldType</a> structure) that has the focus. |
| fldP               | Pointer to the field ( <a href="#">FieldType</a> structure) that has the focus.                                              |      |                                                                                 |
| <b>Result</b>      | Returns nothing.                                                                                                             |      |                                                                                 |
| <b>See Also</b>    | <a href="#">FldPaste</a> , <a href="#">FldCut</a> , <a href="#">FldDelete</a> , <a href="#">FldInsert</a>                    |      |                                                                                 |

## **FldWordWrap**

**Purpose** Given a string and a width, return the number of bytes of characters that can be displayed using the current font.

**Declared In** `Field.h`

**Prototype** `UInt16 FldWordWrap (const Char *chars,  
Int16 maxWidth)`

**Parameters**

|                             |                                      |
|-----------------------------|--------------------------------------|
| <code>-&gt; chars</code>    | Pointer to a null-terminated string. |
| <code>-&gt; maxWidth</code> | Maximum line width in pixels.        |

**Result** Returns the length in bytes of the characters that can be displayed.

**See Also** [FntWordWrap](#)

## **Fields**

*Field Functions*

---

# Find

---

This chapter describes the global find facility API declared in the header file `Find.h`.

## Find Functions

### FindDrawHeader

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw the header line that separates, by application, the list of found items.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | <code>Find.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>   | <code>Boolean FindDrawHeader (FindParamsPtr findParams, Char const* title)</code>                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <code>-&gt; findParams</code> Pointer to the <a href="#">sysAppLaunchCmdFind</a> launch code's parameter block.<br><code>-&gt; title</code> String to display as the title for the current application.                                                                                                                                                                                                                                                  |
| <b>Result</b>      | Returns <code>true</code> if Find screen is filled up. Applications should exit from the search if this occurs.                                                                                                                                                                                                                                                                                                                                          |
| <b>Comments</b>    | Call this function once at the beginning of your application's response to the <a href="#">sysAppLaunchCmdFind</a> launch code. This function draws a header for your application's Find results. The header separates the search results from your application with the search results from another application.<br><br>If your application searches multiple databases, you may also use <code>FindDrawHeader</code> as a separator between databases. |

## Find

### Find Functions

---

## FindGetLineBounds

- Purpose** Returns the bounds of the next available line for displaying a match in the Find results dialog.
- Declared In** Find.h
- Prototype**  
`void FindGetLineBounds  
(const FindParamsType *findParams, RectanglePtr r)`
- Parameters**
- |               |                                                                                   |
|---------------|-----------------------------------------------------------------------------------|
| -> findParams | Pointer to the <a href="#">sysAppLaunchCmdFind</a> launch code's parameter block. |
| <- r          | The bounds of the area that should contain the next line of results.              |
- Result** Returns nothing.

## FindSaveMatch

- Purpose** Saves the record and position within the record of a text search match. This information is saved so that it's possible to later navigate to the match.
- Declared In** Find.h
- Prototype**  
`Boolean FindSaveMatch (FindParamsPtr findParams,  
UInt16 recordNum, UInt16 pos, UInt16 fieldNum,  
UInt32 appCustom, UInt16 cardNo, LocalID dbID)`
- Parameters**
- |               |                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> findParams | Pointer to the <a href="#">sysAppLaunchCmdFind</a> launch code's parameter block.                                                                      |
| -> recordNum  | Record index. This parameter sets the recordNum field in the <a href="#">sysAppLaunchCmdGoto</a> 's parameter block.                                   |
| -> pos        | Offset of the match string from start of record. This parameter sets the matchPos field in the <a href="#">sysAppLaunchCmdGoto</a> 's parameter block. |

- > `fieldNum`      Field number that the string was found in. This parameter sets the `matchFieldNum` field in the [sysAppLaunchCmdGoto](#)'s parameter block.
  
- > `appCustom`      Extra data the application can save with a match. This parameter sets the `matchCustom` field in the [sysAppLaunchCmdGoto](#)'s parameter block.
  
- > `cardNo`          Card number of the database that contains the match. This parameter sets the `dbCardNo` field in the [sysAppLaunchCmdGoto](#)'s parameter block.
  
- > `dbID`             Local ID of the database that contains the match. This parameter sets the `dbID` field in the [sysAppLaunchCmdGoto](#)'s parameter block.

**Result**      Returns `true` if Find screen is filled up. Applications should exit from the search if this occurs.

**Comments**    Call this function when your application finds a record with a matching string ([FindStrInStr](#) or [TxtFindString](#) returns `true`). This function saves the information you pass. If the user clicks this selection in the Find results dialog, the information is retrieved and used to set up the [sysAppLaunchCmdGoto](#) launch code's parameter block.

You can use the `appCustom` field for any application-specific data that might be needed to navigate to the record if the user selects it. It's common for localizable applications to set `appCustom` to the length of the matching string because the global find facility cannot correctly determine the length of the matching string on systems with multi-byte character sets. In some character encodings, one character may be accurately represented as either a single-byte character or a multi-byte character. The `TxtFindString` function accurately matches single-byte characters against their multi-byte equivalents and returns the length of the matching string. If you pass `TxtFindString`'s return value as the `appCustom` parameter to `FindSaveMatch`, the `matchCustom` field of the

## Find

### Find Functions

---

`sysAppLaunchCmdGoTo` parameter block contains the length of the matching string.

If your application requires more custom information, you can store the information in a feature and store the feature number in the `appCustom` field. See the “[Feature Manager](#)” chapter for more information.

## FindStrInStr

**Purpose** Perform a case-blind prefix search for a string in another string. This function assumes that the string to find has already been normalized for searching.

**Declared In** `Find.h`

**Prototype** `Boolean FindStrInStr (Char const *strToSearch, Char const *strToFind, UInt16 *posP)`

**Parameters**

- > `strToSearch` String to search.
- > `strToFind` Normalized version of the text string to be found.
- <- `posP` If a match is found, contains the offset of the match within `strToSearch`.

**Result** Returns `true` if the string was found. `FindStrInStr` matches the beginnings of words only; that is, `strToFind` must be a prefix of one of the words in `strToSearch` for `FindStrInStr` to return `true`.

**Comment** Don't use this function on systems that support the text manager. Instead, use [TxtFindString](#), which performs searches on strings that contain multi-byte characters and returns the length of the matching text.

For backward compatibility with systems that don't support the text manager, use `TxtGlueFindString`, found in the PalmOSGlue library. `TxtGlueFindString` calls `TxtFindString` if the text

manager is present, or `FindStrInStr` if it is not present. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

The method by which a search string is normalized varies depending on the version of Palm OS® and the character encoding supported by the device. The string passed to your application in the `strToFind` field of the `sysAppLaunchCmdFind` launch code parameter block has already been normalized. It can be passed directly to `FindStrInStr`, `TxtFindString`, or `TxtGlueFindString`. If you need to create your own normalized search string, use `TxtGluePrepFindString`, also in the PalmOSGlue library.

### *Find Functions*

---

# Forms

---

This chapter provides the following information about form objects:

- [Form Data Structures](#)
- [Form Constants](#)
- [Form Resources](#)
- [Form Functions](#)
- [Application-Defined Functions](#)

The header file `Form.h` declares the API that this chapter describes. For more information on forms, see the section “[Text](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Form Data Structures

### FormAttrType

The `FormAttrType` bit field defines the visible characteristics of the form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 usable           :1;
    UInt16 enabled         :1;
    UInt16 visible         :1;
    UInt16 dirty           :1;
    UInt16 saveBehind      :1;
    UInt16 graffitiShift   :1;
```

## Forms

### Form Data Structures

---

```
    UInt16 globalsAvailable : 1;  
    UInt16 doingDialog : 1;  
    UInt16 exitDialog : 1;  
    UInt16 reserved : 7;  
    UInt16 reserved2;  
} FormAttrType;
```

Your code should treat the `FormAttrType` bit field as opaque. Do not attempt to change bit field member values directly.

#### Field Descriptions

|                               |                                                                                                                          |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>usable</code>           | Not set if the form is not considered part of the current interface of the application, and it doesn't appear on screen. |
| <code>enabled</code>          | Not used.                                                                                                                |
| <code>visible</code>          | Set or cleared internally when the field object is drawn or erased.                                                      |
| <code>dirty</code>            | Not used.                                                                                                                |
| <code>saveBehind</code>       | Set if the bits behind the form are saved when the form is drawn.                                                        |
| <code>graffitiShift</code>    | Set if the graffiti shift indicator is supported.                                                                        |
| <code>globalsAvailable</code> | System use only.                                                                                                         |
| <code>doingDialog</code>      | System use only.                                                                                                         |
| <code>exitDialog</code>       | System use only.                                                                                                         |
| <code>reserved</code>         | Reserved for system use.                                                                                                 |
| <code>reserved2</code>        | Reserved for system use.                                                                                                 |

**Compatibility** The `globalsAvailable`, `doingDialog`, and `exitDialog` flags are present only if [3.5 New Feature Set](#) is present.

## FormBitmapType

The `FormBitmapType` structure defines the visible characteristics of a bitmap on a form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormBitmapType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    FormObjAttrType  attr;
    PointType        pos;
    UInt16           rscID;
} FormBitmapType;
```

### Field Descriptions

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>attr</code>  | See <a href="#">FormObjAttrType</a> .                                                                                                                                   |
| <code>pos</code>   | Location of the bitmap.                                                                                                                                                 |
| <code>rscID</code> | Resource ID of the bitmap. If you use <a href="#">DmGetResource</a> with this value as the resource ID, it returns a pointer to a <a href="#">BitmapType</a> structure. |

## FormFrameType

The `FormFrameType` structure defines a frame that appears on the form.

```
typedef struct {
    UInt16           id;
    FormObjAttrType  attr;
    RectangleType    rect;
    UInt16           frameType;
} FormFrameType;
```

## Forms

### Form Data Structures

---

#### Field Descriptions

|           |                                       |
|-----------|---------------------------------------|
| id        | ID of the frame.                      |
| attr      | See <a href="#">FormObjAttrType</a> . |
| rect      | Location and size of the frame.       |
| frameType | The type of frame.                    |

#### FormGadgetAttrType

The `FormGadgetAttrType` bit field defines a gadget's attributes.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormGadgetAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 usable : 1;
    UInt16 extended : 1;
    UInt16 visible : 1;
    UInt16 reserved : 13;
} FormGadgetAttrType;
```

Your code should treat the `FormGadgetAttrType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

### Field Descriptions

- usable** Not set if the gadget is not considered part of the current interface of the application, and it doesn't appear on screen. This is set by [FrmShowObject](#) and cleared by [FrmHideObject](#).
- extended** If set, the gadget is an extended gadget. Extended gadgets are supported if [3.5 New Feature Set](#) is present. An extended gadget has the `handler` field defined in its [FormGadgetType](#). If not set, the gadgets is a standard gadget compatible with all releases of Palm OS®.
- visible** Set or cleared when the gadget is drawn or erased. [FrmHideObject](#) clears this value. You should set it explicitly in the gadget's callback function (if it has one) in response to a draw request.
- reserved** Reserved for future use.

Many form functions ([FrmGetObjectType](#), [FrmHideObject](#), and [FrmGetObjectBounds](#), for example) take an object index as one of their arguments. The most common way to get an object's index is to call [FrmGetObjectIndex](#). [FrmGetObjectIndex](#) takes a form ID and returns the form object's index. This is the routine one should use in most cases, because the application usually knows the object ID. However, gadgets and specifically extended gadgets, have APIs with callbacks that pass back the gadget pointer and not the ID. In those cases, the only way to get the object index (so one can use the [FrmGetObject\\*](#) APIs) is to use the function [FrmGetObjectIndexFromPtr](#).

If you need the same functionality on pre-Palm OS 4.0 systems then you can accomplish the same thing with the following code snippet.

---

```
UInt16 index;
UInt16 objIndex = frmInvalidObjectId;
UInt16 numObjects = FrmGetNumberOfObjects(frmP)
for (index = 0; index < numObjects; index++) {
    if (FrmGetObjectPtr(index) == myObjPtr) {
        // Found it
        objIndex = index;
        break;
    }
}
```

## Forms

### *Form Data Structures*

---

```
    }  
}
```

---

**Compatibility** This type is defined only if [3.5 New Feature Set](#) is present.

## FormGadgetType

The `FormGadgetType` structure defines a gadget object that appears on a form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormGadgetType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 id;
    FormGadgetAttrType attr;
    RectangleType rect;
    const void *data;
    FormGadgetHandlerType *handler;
} FormGadgetType;
```

Your code should treat the `FormGadgetType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

### Field Descriptions

|                      |                                                                                                                                                                                     |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>id</code>      | ID of the gadget resource.                                                                                                                                                          |
| <code>attr</code>    | See <a href="#">FormGadgetAttrType</a> .                                                                                                                                            |
| <code>rect</code>    | Location and size of the object.                                                                                                                                                    |
| <code>data</code>    | Pointer to any specific data that needs to be stored. You can set and retrieve the value of this field with <a href="#">FrmGetGadgetData</a> and <a href="#">FrmSetGadgetData</a> . |
| <code>handler</code> | Pointer to a callback function that controls the gadget's behavior and responds to events. You can set this field with <a href="#">FrmSetGadgetHandler</a> .                        |

Many form functions ([FrmGetObjectType](#), [FrmHideObject](#), and [FrmGetObjectBounds](#), for example) take an object index as one of their arguments. The most common way to get an object's index is to

## Forms

### Form Data Structures

---

call [FrmGetObjectIndex](#). `FrmGetObjectIndex` takes a form ID and returns the form object's index. This is the routine one should use in most cases, because the application usually knows the object ID. However, gadgets have APIs with callbacks that pass back the gadget pointer and not the ID. In those cases, the only way to get the object index (so one can use the `FrmGetObject*` APIs) is to use the function [FrmGetObjectIndexFromPtr](#).

If you need the same functionality on pre-Palm OS 4.0 systems then you can accomplish the same thing with the following code snippet.

---

```
UInt16 index;
UInt16 objIndex = frmInvalidObjectId;
UInt16 numObjects = FrmGetNumberOfObjects(frmP)
for (index = 0; index < numObjects; index++) {
    if (FrmGetObjectPtr(index) == myObjPtr) {
        // Found it
        objIndex = index;
        break;
    }
}
```

---

### Compatibility

In Palm OS® releases prior to 3.5, the `attr` field was of type [FormObjAttrType](#) and the `handler` field did not exist.

## FormGadgetTypeInCallback

The `FormGadgetTypeInCallback` structure is passed to your extended gadget handler and is identical to [FormGadgetType](#) except that its contents are *not* hidden when `DO_NOT_ALLOW_ACCESS_TO_INTERNALS_OF_STRUCTS` is defined. This allows you to freely access the contents of an extended gadget structure from within your extended gadget callback functions.

```
typedef struct {
    UInt16 id;
    FormGadgetAttrType attr;
    RectangleType rect;
    const void *data;
    FormGadgetHandlerType *handler;
} FormGadgetTypeInCallback;
```

### Field Descriptions

|         |                                                                                            |
|---------|--------------------------------------------------------------------------------------------|
| id      | ID of the gadget resource.                                                                 |
| attr    | See <a href="#">FormGadgetAttrType</a> .                                                   |
| rect    | Location and size of the object.                                                           |
| data    | Pointer to any specific data that needs to be stored.                                      |
| handler | Pointer to a callback function that controls the gadget's behavior and responds to events. |

Many form functions ([FrmGetObjectType](#), [FrmHideObject](#), and [FrmGetObjectBounds](#), for example) take an object index as one of their arguments. The most common way to get an object's index is to call [FrmGetObjectIndex](#). `FrmGetObjectIndex` takes a form ID and returns the form object's index. This is the routine one should use in most cases, because the application usually knows the object ID. However, extended gadgets have APIs with callbacks that pass back the gadget pointer and not the ID. In those cases, the only way to get the object index (so one can use the `FrmGetObject*` APIs) is to use the function [FrmGetObjectIndexFromPtr](#).

If you need the same functionality on pre-Palm OS 4.0 systems then you can accomplish the same thing with the following code snippet.

---

```
UInt16 index;
UInt16 objIndex = frmInvalidObjectId;
UInt16 numObjects = FrmGetNumberOfObjects(frmP)
for (index = 0; index < numObjects; index++) {
    if (FrmGetObjectPtr(index) == myObjPtr) {
        // Found it
        objIndex = index;
        break;
    }
}
```

---

**Compatibility** Introduced in the Palm OS 4.0 SDK Update 1.

### FormLabelType

The `FormLabelType` structure defines a label that appears on a form.

## Forms

### Form Data Structures

---

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormLabelType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16      id;
    PointType   pos;
    FormObjAttrType attr;
    FontID      fontID;
    UInt8       reserved;
    Char        *text;
} FormLabelType;
```

Your code should treat the `FormLabelType` structure as opaque. Do not attempt to change structure member values directly.

#### Field Descriptions

|                       |                                         |
|-----------------------|-----------------------------------------|
| <code>id</code>       | Resource ID of the label.               |
| <code>pos</code>      | Location of the label.                  |
| <code>attr</code>     | See <a href="#">FormObjAttrType</a> .   |
| <code>fontID</code>   | Font ID of the font used for the label. |
| <code>reserved</code> | Reserved for future use.                |
| <code>text</code>     | Text of the label.                      |

#### FormLineType

The `FormLineType` structure defines a line appearing on a form.

```
typedef struct {
    FormObjAttrType attr;
    PointType       point1;
    PointType       point2;
} FormLineType;
```

Your code should treat the `FormLineType` structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|                     |                                       |
|---------------------|---------------------------------------|
| <code>attr</code>   | See <a href="#">FormObjAttrType</a> . |
| <code>point1</code> | Starting point of the line.           |
| <code>point2</code> | Ending point of the line.             |

## FormObjAttrType

The `FormObjAttrType` bit field defines a form object's attributes.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormObjAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 usable : 1;
    UInt16 reserved : 15;
} FormObjAttrType;
```

Your code should treat the `FormObjAttrType` structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|                       |                                                                                                                            |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------|
| <code>usable</code>   | Not set if the object is not considered part of the current interface of the application, and it doesn't appear on screen. |
| <code>reserved</code> | Reserved for future use.                                                                                                   |

## FormObjectKind

The `FormObjectKind` enum specifies values for the `objectType` field of the [FormObjListType](#). It specifies how to interpret the `object` field.

## Forms

### Form Data Structures

---

```
enum formObjects {
    frmFieldObj,
    frmControlObj,
    frmListObj,
    frmTableObj,
    frmBitmapObj,
    frmLineObj,
    frmFrameObj,
    frmRectangleObj,
    frmLabelObj,
    frmTitleObj,
    frmPopupObj,
    frmGraffitiStateObj,
    frmGadgetObj,
    frmScrollbarObj,
};
typedef enum formObjects FormObjectKind;
```

#### Value Descriptions

|                     |                           |
|---------------------|---------------------------|
| frmFieldObj         | Text field                |
| frmControlObj       | Control                   |
| frmListObj          | List                      |
| frmTableObj         | Table                     |
| frmBitmapObj        | Form bitmap               |
| frmLineObj          | Line                      |
| frmFrameObj         | Frame                     |
| frmRectangleObj     | Rectangle                 |
| frmLabelObj         | Label                     |
| frmTitleObj         | Form title                |
| frmPopupObj         | Popup list                |
| frmGraffitiStateObj | Graffiti® state indicator |

|                 |                        |
|-----------------|------------------------|
| frmGadgetObj    | Gadget (custom object) |
| frmScrollbarObj | Scrollbar              |

## FormObjectType

The FormObjectType union points to the C structure for a user interface object that appears on the form.

```
typedef union {
    void                *ptr;
    FieldType           *field;
    ControlType         *control;
    GraphicControlType  *graphicControl;
    SliderControlType   *sliderControl;
    ListType            *list;
    TableType           *table;
    FormBitmapType      *bitmap;
    FormLabelType       *label;
    FormTitleType       *title;
    FormPopupType       *popup;
    FormGraffitiStateType *grfState;
    FormGadgetType      *gadget;
    ScrollBarType       *scrollBar;
} FormObjectType;
```

Your code should treat the FormObjectType structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|                |                                                                    |
|----------------|--------------------------------------------------------------------|
| ptr            | Used when the object's type is not one of those specified below.   |
| field          | Text field's structure. See <a href="#">FieldType</a> .            |
| control        | Control's structure. See <a href="#">ControlType</a> .             |
| graphicControl | Graphic button structure. See <a href="#">GraphicControlType</a> . |
| sliderControl  | Slider control structure. See <a href="#">SliderControlType</a> .  |

## Forms

### Form Data Structures

---

|                        |                                                                                  |
|------------------------|----------------------------------------------------------------------------------|
| <code>list</code>      | List object's structure. See <a href="#">ListType</a> .                          |
| <code>table</code>     | Table structure. See <a href="#">TableType</a> .                                 |
| <code>bitmap</code>    | Form bitmap's structure. See <a href="#">FormBitmapType</a> .                    |
| <code>label</code>     | Label's structure. See <a href="#">FormLabelType</a> .                           |
| <code>title</code>     | Form title's structure. See <a href="#">FormTitleType</a> .                      |
| <code>popup</code>     | Popup list's structure. See <a href="#">FormPopupType</a> .                      |
| <code>grfState</code>  | Graffiti shift indicator's structure. See <a href="#">FrmGraffitiStateType</a> . |
| <code>gadget</code>    | Gadget (custom UI resource) structure. See <a href="#">FormGadgetType</a> .      |
| <code>scrollbar</code> | Scroll bar's structure. See <a href="#">ScrollBarType</a> .                      |

**Compatibility** The `graphicControl` and `sliderControl` fields are only defined if [3.5 New Feature Set](#) is present.

## FormObjListType

The `FormObjListType` structure specifies a user interface object that appears on the form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormObjListType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    FormObjectKind    objectType;
    UInt8             reserved;
    FormObjectType    object;
} FormObjListType;
```

Your code should treat the `FormObjListType` structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|            |                                                                                               |
|------------|-----------------------------------------------------------------------------------------------|
| objectType | Specifies the type of the object (control, field, etc.). See <a href="#">FormObjectKind</a> . |
| reserved   | Reserved for future use.                                                                      |
| object     | The C data structure that defines the object. See <a href="#">FormObjectType</a> .            |

### FormPopupType

The FormPopupType structure defines a popup list that appears on a form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the FormPopupType structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

## Forms

### Form Data Structures

---

```
typedef struct {
    UInt16      controlID;
    UInt16      listID;
} FormPopupType;
```

Your code should treat the `FormPopupType` structure as opaque. Do not attempt to change structure member values directly.

#### Field Descriptions

`controlID` Resource ID of the popup trigger control that triggers the list's display.

`listID` Resource ID of the list object that defines the popup list.

### FormPtr

The `FormPtr` type defines a pointer to a [FormType](#) structure.

```
typedef FormType *FormPtr;
```

### FormRectangleType

The `FormRectangleType` structure defines a rectangle that appears on the form.

```
typedef struct {
    FormObjAttrType attr;
    RectangleType   rect;
} FormRectangleType;
```

Your code should treat the `FormRectangleType` structure as opaque. Do not attempt to change structure member values directly.

#### Field Descriptions

`attr` See [FormObjAttrType](#).

`rect` Location and size of the rectangle.

## FormTitleType

The `FormTitleType` structure defines the title of the form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormTitleType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    RectangleType  rect;
    char           *text;
} FormTitleType;
```

Your code should treat the `FormTitleType` structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|                   |                                          |
|-------------------|------------------------------------------|
| <code>rect</code> | The location and size of the title area. |
| <code>text</code> | Text of the title.                       |

## FormType

The `FormType` structure and supporting structures are defined below.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FormType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    WindowType      window;
    UInt16          formId;
    FormAttrType    attr;
    WinHandle       bitsBehindForm;
    FormEventHandlerType *handler;
```

## Forms

### Form Data Structures

---

```
        UInt16          focus;  
        UInt16          defaultButton;  
        UInt16          helpRscId;  
        UInt16          menuRscId;  
        UInt16          numObjects;  
        FormObjListType *objects;  
    } FormType;
```

Your code should treat the `FormType` structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|                             |                                                                                                                                                                                                                                                                  |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>window</code>         | Structure of the window object that corresponds to the form. See <a href="#">WindowType</a> . Access this field with <a href="#">FrmGetWindowHandle</a> .                                                                                                        |
| <code>formId</code>         | ID number of the form, specified by the application developer. This ID value is part of the event data of <a href="#">frmOpenEvent</a> . The ID should match the form's resource ID. Access this field with <a href="#">FrmGetFormId</a> .                       |
| <code>attr</code>           | Form object attributes. See <a href="#">FormAttrType</a> .                                                                                                                                                                                                       |
| <code>bitsBehindForm</code> | Used to save all the bits behind the form so the screen can be properly refreshed when the form is closed. This field is for internal use only by modal forms.                                                                                                   |
| <code>handler</code>        | Routine called when the form needs to handle an event. You typically set this in your application's event handling function by calling <a href="#">FrmSetEventHandler</a> .                                                                                      |
| <code>focus</code>          | Index of a field or table object within the form that contains the focus. Any <a href="#">keyDownEvent</a> is passed to the object that has the focus. Set to <code>noFocus</code> if no object has the focus. Set this field with <a href="#">FrmSetFocus</a> . |

|                            |                                                                                                                          |
|----------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>defaultButton</code> | Resource ID of the object defined as the default button. This value is used by the routine <a href="#">FrmDoDialog</a> . |
| <code>helpRscId</code>     | Resource ID number of the help resource. The help resource is a String resource (type <code>tSTR</code> ).               |
| <code>menuRscId</code>     | ID number of a menu bar to use if the form has a menu, or zero if the form doesn't have a menu.                          |
| <code>numObjects</code>    | Number of objects contained within the form. Access this field with <a href="#">FrmGetNumberOfObjects</a> .              |
| <code>objects</code>       | Pointer to the array of objects contained within the form. See <a href="#">FormObjListType</a> .                         |

## **FrmGraffitiStateType**

The `FrmGraffitiStateType` structure defines the graffiti shift indicator.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `FrmGraffitiStateType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct{
    PointerType    pos;
}FrmGraffitiStateType;
```

Your code should treat the `FrmGraffitiStateType` structure as opaque. Do not attempt to change structure member values directly.

### **Field Descriptions**

`pos`                      Location of the graffiti shift indicator.

## Forms

### Form Constants

---

## Form Constants

The following form constants are defined:

| Constant                          | Value               | Description                                                                                                      |
|-----------------------------------|---------------------|------------------------------------------------------------------------------------------------------------------|
| <code>noFocus</code>              | <code>0xffff</code> | No form object has the focus                                                                                     |
| <code>frmRedrawUpdateCode</code>  | <code>0x8000</code> | Indicates that the form should be redrawn; flag in a <a href="#">frmUpdateEvent</a> .                            |
| <code>frmNoSelectedControl</code> | <code>0xff</code>   | Returned by <a href="#">FrmGetControlGroupSelection</a> if no control is selected.                               |
| <code>frmResponseCreate</code>    | <code>1974</code>   | Passed to <a href="#">FormCheckResponseFuncType</a> to indicate that the function should perform initialization. |
| <code>frmResponseQuit</code>      | <code>0xBEEF</code> | Passed to <a href="#">FormCheckResponseFuncType</a> to indicate that the function should perform cleanup.        |

---

## Form Resources

The following resources are associated with forms and with the objects on a form whose data structures are defined above:

- Form—[Form Resource](#) (tFRM)
- Alert dialog— [Alert Resource](#) (Talt)
- Bitmap—[Form Bitmap Resource](#) (tFBM)
- Button—[Button Resource](#) (tBTN)
- Check box—[Check Box Resource](#) (tCBX)
- Field—[Field Resource](#) (tFLD)
- Gadget (custom object)— [Gadget Resource](#) (tGDT)
- Graffiti shift indicator —[Graffiti Shift Indicator Resource](#) (tGSI)
- Label—[Label Resource](#) (tLBL)

- List—[List Resource](#) (tLST)
- Popup trigger—[Popup Trigger Resource](#) (tPUT)
- Push button—[Push Button Resource](#) (tPBN)
- Repeating button—[Repeating Button Resource](#) (tREP)
- Scrollbar—[Scroll Bar Resource](#) (tSCL)
- Selector trigger—[Selector Trigger Resource](#) (tSLT)
- Table—[Table Resource](#) (tTBL)

## Form Functions

### FrmAlert

|                    |                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Create a modal dialog from an alert resource and display it until the user selects a button in the dialog.                                                                     |
| <b>Declared In</b> | Form.h                                                                                                                                                                         |
| <b>Prototype</b>   | UInt16 FrmAlert (UInt16 alertId)                                                                                                                                               |
| <b>Parameters</b>  | -> alertId            ID of the alert resource.                                                                                                                                |
| <b>Result</b>      | Returns the item number of the button the user selected. A button's item number is determined by its order in the alert dialog; the first button has the item number 0 (zero). |

---

**NOTE:** A default button press is simulated if the user switches to a different application while a modal dialog is active.

---

**See Also**    [FrmDoDialog](#), [FrmCustomAlert](#), [FrmCustomResponseAlert](#)

## Forms

### Form Functions

---

## FrmCloseAllForms

- Purpose** Send a [frmCloseEvent](#) to all open forms.
- Declared In** `Form.h`
- Prototype** `void FrmCloseAllForms (void)`
- Parameters** None.
- Result** Returns nothing.
- Comments** Applications can call this function to ensure that all forms are closed cleanly before exiting [PilotMain](#); that is, before termination.
- See Also** [FrmSaveAllForms](#)

## FrmCopyLabel

- Purpose** Copy the passed string into the data structure of the specified label object in the active form.
- Declared In** `Form.h`
- Prototype** `void FrmCopyLabel (FormType *formP, UInt16 labelID, const Char *newLabel)`
- Parameters**
- |             |                                                                   |
|-------------|-------------------------------------------------------------------|
| -> formP    | Pointer to the form object ( <a href="#">FormType</a> structure). |
| -> labelID  | ID of form label object.                                          |
| -> newLabel | Pointer to a null-terminated string.                              |
- Result** Returns nothing.
- Comments** The size of the new label **must not** exceed the size of the label defined in the resource. When defining the label in the resource, specify an initial size at least as big as any of the strings that will be

assigned dynamically. This function redraws the label if the form's `usable` attribute and the label's `visible` attribute are set.

This function redraws the label but does not erase the old one first. If the new label is shorter than the old one, the end of the old label will still be visible. To avoid this, you can hide the label using [FrmHideObject](#), then show it using [FrmShowObject](#), after using `FrmCopyLabel`.

Note that `FrmCopyLabel` copies the passed string into memory already allocated for the label. Thus, the string doesn't need to remain in existence once `FrmCopyLabel` returns.

**See Also** [FrmGetLabel](#)

## **FrmCopyTitle**

**Purpose** Copy a new title over the form's current title. If the form is visible, the new title is drawn.

**Declared In** `Form.h`

**Prototype**

```
void FrmCopyTitle (FormType *formP,  
const Char *newTitle)
```

**Parameters**

|                          |                                                                   |
|--------------------------|-------------------------------------------------------------------|
| -> <code>formP</code>    | Pointer to the form object ( <a href="#">FormType</a> structure). |
| -> <code>newTitle</code> | Pointer to the new title string.                                  |

**Result** Returns nothing.

**Comments** The size of the new title **must not** exceed the title size defined in the resource. When defining the title in the resource, specify an initial size at least as big as any of the strings to be assigned dynamically.

**See Also** [FrmGetTitle](#), [FrmSetTitle](#)

## **FrmCustomAlert**

- Purpose** Create a modal dialog from an alert resource and display the dialog until the user taps a button in the alert dialog.
- Declared In** `Form.h`
- Prototype**  
`UInt16 FrmCustomAlert (UInt16 alertId,  
const Char *s1, const Char *s2, const Char *s3)`
- Parameters**
- > `alertId` Resource ID of the alert.
  - > `s1, s2, s3` Strings to replace ^1, ^2, and ^3 (see Comments).
- Result** Returns the number of the button the user tapped (the first button is zero).
- Comments** A button's item number is determined by its order in the alert template; the first button has the item number zero.
- Up to three strings can be passed to this routine. They are used to replace the variables ^1, ^2 and ^3 that are contained in the message string of the alert resource.
- If the variables ^1, ^2, and ^3 occur in the message string, do not pass NULL for the arguments `s1`, `s2`, and `s3`. If you want an argument to be ignored, pass the empty string (""). In Palm OS 2.0 or below, pass a string containing a space (" ") instead of the empty string.
- 
- NOTE:** A default button press is simulated if the user switches to a different application while a modal dialog is active.
- 

**See Also** [FrmAlert](#), [FrmDoDialog](#), [FrmCustomResponseAlert](#)

## FrmCustomResponseAlert

- Purpose** Create a modal dialog with a text field from an alert resource and display it until the user taps a button in the alert dialog.
- Declared In** `Form.h`
- Prototype**  
`UInt16 FrmCustomResponseAlert (UInt16 alertId,  
const Char *s1, const Char *s2, const Char *s3,  
Char *entryStringBuf, Int16 entryStringBufLength,  
FormCheckResponseFuncPtr callback)`
- Parameters**
- > `alertId` Resource ID of the alert.
  - > `s1, s2, s3` Strings to replace ^1, ^2, and ^3. See the Comments in [FrmCustomAlert](#) for more information.
  - <- `entryStringBuf` The string the user entered in the text field.
  - > `entryStringBufLength` The maximum length for the string in `entryStringBuf`.
  - > `callback` A callback function that processes the string. See [FormCheckResponseFuncType](#). Pass NULL if there is no callback.
- Result** Returns the number of the button the user tapped (the first button is zero).
- Comments** This function differs from [FrmCustomAlert](#) in these ways:
- The dialog it displays contains a text field for user entry. The text that the user enters is returned in the `entryStringBuf` parameter.
  - When the user taps a button, the `callback` function is called and is passed the button number and `entryStringBuf`. The dialog is only dismissed if the callback returns `true`. This behavior allows you to perform error checking on the

## Forms

### Form Functions

---

string that the user entered and give the user a chance to re-enter the string.

The callback function is also called with special constants when the alert dialog is being initialized and when it is being deallocated. This allows the callback to perform any necessary initialization and cleanup.

---

**NOTE:** A default button press is simulated if the user switches to a different application while a modal dialog is active.

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [FrmAlert](#), [FrmDoDialog](#)

## FrmDeleteForm

**Purpose** Release the memory occupied by a form. Any memory allocated to objects in the form is also released.

**Declared In** `Form.h`

**Prototype** `void FrmDeleteForm (FormType *formP)`

**Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).

**Result** Returns nothing.

**Comments** This function doesn't modify the display.

**Compatibility** If [3.5 New Feature Set](#) is present and the form contains an extended gadget, this function calls the gadget's callback with `formGadgetDeleteCmd`. See [FormGadgetHandlerType](#).

**See Also** [FrmInitForm](#), [FrmReturnToForm](#)

## FrmDispatchEvent

- Purpose** Dispatch an event to the application's handler for the form.
- Declared In** `Form.h`
- Prototype** `Boolean FrmDispatchEvent (EventType *eventP)`
- Parameters** `-> eventP` Pointer to an event.
- Result** Returns the Boolean value returned by the form's event handler or [FrmHandleEvent](#). (If the form's event handler returns `false`, the event is passed to `FrmHandleEvent`.) This function also returns `false` if the form specified in the event is invalid.
- Comments** The event is dispatched to the current form's handler unless the form ID is specified in the event data, as, for example, with [frmOpenEvent](#) or [frmGotoEvent](#). A form's event handler ([FormEventHandlerType](#)) is registered by [FrmSetEventHandler](#).
- Note that if the form does not have a registered event handler, this function causes a fatal error.

## FrmDoDialog

- Purpose** Display a modal dialog until the user taps a button in the dialog.
- Declared In** `Form.h`
- Prototype** `UInt16 FrmDoDialog (FormType *formP)`
- Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).
- Result** Returns the resource ID of the button the user tapped.

## Forms

### Form Functions

---

---

**NOTE:** A default button press is simulated if the user switches to a different application while a modal dialog is active.

---

**Comments** Before calling `FrmDoDialog` you must have called [FrmInitForm](#) to load and initialize the dialog and you must have then set the event handler, if one is needed. After the call, read any values needed from the dialog's objects and then call [FrmDeleteForm](#) to release the memory occupied by the dialog.

**See Also** [FrmInitForm](#), [FrmCustomAlert](#), [FrmCustomResponseAlert](#)

## FrmDrawForm

**Purpose** Draw all objects in a form and the frame around the form.

**Declared In** `Form.h`

**Prototype** `void FrmDrawForm (FormType *formP)`

**Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).

**Result** Returns nothing.

**Comments** If the `saveBehind` form attribute is set and the form is visible, this function saves the bits behind the form using the `bitsBehindForm` field in the `FormType` structure.

You should call this function in response to a [frmOpenEvent](#).

If you do any custom drawing, you should do so after you call this function not before. If you do custom drawing, respond to [frmUpdateEvent](#) as well as `frmOpenEvent`, and be sure to return true to specify that the `frmUpdateEvent` was handled. The default event handler for `frmUpdateEvent` calls `FrmDrawForm`, so if you allow the event to fall through by returning false, your custom drawing is erased.

**Compatibility** If [3.5 New Feature Set](#) is present, `FrmDrawForm` erases the form's window before performing any drawing. Thus, it is especially important to do any custom drawing after this function call on Palm OS 3.5 and higher.

If [3.5 New Feature Set](#) is present and the form contains an extended gadget, this function calls the gadget's callback with `formGadgetDrawCmd`. See [FormGadgetHandlerType](#).

**See Also** [FrmEraseForm](#), [FrmInitForm](#)

## **FrmEraseForm**

**Purpose** Erase a form from the display.

**Declared In** `Form.h`

**Prototype** `void FrmEraseForm (FormType *formP)`

**Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).

**Result** Returns nothing.

**Comments** If the region obscured by the form was saved by [FrmDrawForm](#), this function restores that region.

## Forms

### Form Functions

---

## FrmGetActiveField

- Purpose** Return the active field for a specified form.
- Declared In** `Form.h`
- Prototype**  
`FieldType *FrmGetActiveField  
(const FormType *formP)`
- Parameters** `-> formP` Pointer to the form for which the active field should be returned, or `NULL` if the active field on the active form is desired.
- Result** Returns a pointer to the field object of the active field, or `NULL` if the form doesn't have an active field or if there is no active form.
- Comments** This function will most often be called with a `NULL` parameter to obtain the active field on the active form.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [FrmGetActiveForm](#)

## FrmGetActiveForm

- Purpose** Return the currently active form.
- Declared In** `Form.h`
- Prototype** `FormType *FrmGetActiveForm (void)`
- Parameters** None.
- Result** Returns a pointer to the form object of the active form.
- Comments** You should not call the `FrmGetActiveForm` function when a popup window is open. There is no active form while a popup is

displayed, and the value returned from `FrmGetActiveForm` in this situation has no meaning.

**See Also** [FrmGetActiveField](#), [FrmGetActiveFormID](#), [FrmSetActiveForm](#)

## **FrmGetActiveFormID**

**Purpose** Return the ID of the currently active form.

**Declared In** `Form.h`

**Prototype** `UInt16 FrmGetActiveFormID (void)`

**Parameters** None.

**Result** Returns the active form's ID number.

**See Also** [FrmSetActiveForm](#)

## **FrmGetControlGroupSelection**

**Purpose** Return the item number of the control selected in a group of controls.

**Declared In** `Form.h`

**Prototype** `UInt16 FrmGetControlGroupSelection  
(const FormType *formP, UInt8 groupNum)`

**Parameters**

|             |                                                                   |
|-------------|-------------------------------------------------------------------|
| -> formP    | Pointer to the form object ( <a href="#">FormType</a> structure). |
| -> groupNum | Control group number.                                             |

**Result** Returns the item number of the selected control; returns `frmNoSelectedControl` if no item is selected.

## Forms

### Form Functions

---

**Comments** The item number is the index into the form object's data structure.

---

**NOTE:** `FrmSetControlGroupSelection` sets the selection in a control group based on an object ID, **not** its index, which `FrmGetControlGroupSelection` returns.

---

**Compatibility** On versions prior to 3.5, this function returned a `Byte` instead of `UInt16`.

**See Also** [FrmGetObjectId](#), [FrmGetObjectPtr](#),  
[FrmSetControlGroupSelection](#)

## FrmGetControlValue

**Purpose** Return the current value of a control.

**Declared In** `Form.h`

**Prototype** `Int16 FrmGetControlValue (const FormType *formP,  
UInt16 objIndex)`

**Parameters**

|                             |                                                                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; formP</code>    | Pointer to the form object ( <a href="#">FormType</a> structure).                                                                 |
| <code>-&gt; objIndex</code> | Index of the control object in the form object's data structure. You can obtain this by using <a href="#">FrmGetObjectIndex</a> . |

**Result** Returns the current value of the control. For most controls the return value is either 0 (off) or 1 (on). For sliders, this function returns the value of the value field.

**Comments** The caller must specify a valid index. This function is valid only for push button and check box control objects.

**See Also** [FrmSetControlValue](#)

## FrmGetFirstForm

- Purpose** Return the first form in the window list.
- Declared In** `Form.h`
- Prototype** `FormType *FrmGetFirstForm (void)`
- Parameters** None.
- Result** Returns a pointer to a form object, or NULL if there are no forms.
- Comments** The window list is a LIFO stack. The last window created is the first window in the window list.

## FrmGetFocus

- Purpose** Return the item (index) number of the object that has the focus.
- Declared In** `Form.h`
- Prototype** `UInt16 FrmGetFocus (const FormType *formP)`
- Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).
- Result** Returns the index of the object (UI element) that has the focus, or returns `noFocus` if none does. To convert the object index to an ID, use [FrmGetObjectID](#).
- See Also** [FrmGetObjectPtr](#), [FrmSetFocus](#)

## Forms

### Form Functions

---

#### FrmGetFormBounds

- Purpose** Return the visual bounds of the form; the region returned includes the form's frame.
- Declared In** `Form.h`
- Prototype** `void FrmGetFormBounds (const FormType *formP, RectangleType *rP)`
- Parameters**
- |                          |                                                                                 |
|--------------------------|---------------------------------------------------------------------------------|
| <code>-&gt; formP</code> | Pointer to the form object ( <a href="#">FormType</a> structure).               |
| <code>&lt;- rP</code>    | Pointer to a <code>RectangleType</code> structure where the bounds is returned. |
- Result** Returns nothing. The bounds of the form are returned in `r`.

#### FrmGetFormId

- Purpose** Return the resource ID of a form.
- Declared In** `Form.h`
- Prototype** `UInt16 FrmGetFormId (const FormType *formP)`
- Parameters**
- |                          |                                                                   |
|--------------------------|-------------------------------------------------------------------|
| <code>-&gt; formP</code> | Pointer to the form object ( <a href="#">FormType</a> structure). |
|--------------------------|-------------------------------------------------------------------|
- Result** Returns form resource ID.
- See Also** [FrmGetFormPtr](#)

## FrmGetFormPtr

- Purpose** Return a pointer to the form that has the specified ID.
- Declared In** `Form.h`
- Prototype** `FormType *FrmGetFormPtr (UInt16 formId)`
- Parameters** `-> formId` Form ID number.
- Result** Returns a pointer to the form object, or NULL if the form is not in memory.
- See Also** [FrmGetFormId](#)

## FrmGetGadgetData

- Purpose** Return the value stored in the `data` field of the gadget object.
- Declared In** `Form.h`
- Prototype** `void *FrmGetGadgetData (const FormType *formP, UInt16 objIndex)`
- Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).  
`-> objIndex` Index of the gadget object in the form object's data structure. You can obtain this by using [FrmGetObjectIndex](#).
- Result** Returns a pointer to the custom gadget's data.
- Comments** Gadget objects provide a way for an application to attach custom gadgetry to a form. In general, the `data` field of a gadget object contains a pointer to the custom object's data structure.
- See Also** [FrmSetGadgetData](#), [FrmSetGadgetHandler](#)

## Forms

### Form Functions

---

#### FrmGetLabel

- Purpose** Return pointer to the text of the specified label object in the specified form.
- Declared In** `Form.h`
- Prototype** `const Char *FrmGetLabel (const FormType *formP, UInt16 labelID)`
- Parameters**
- |            |                                                                   |
|------------|-------------------------------------------------------------------|
| -> formP   | Pointer to the form object ( <a href="#">FormType</a> structure). |
| -> labelID | ID of the label object.                                           |
- Result** Returns a pointer to the label string.
- Comments** Does not make a copy of the string; returns a pointer to the string. The object must be a label.
- See Also** [FrmCopyLabel](#)

#### FrmGetNumberOfObjects

- Purpose** Return the number of objects in a form.
- Declared In** `Form.h`
- Prototype** `UInt16 FrmGetNumberOfObjects (const FormType *formP)`
- Parameters**
- |          |                                                                   |
|----------|-------------------------------------------------------------------|
| -> formP | Pointer to the form object ( <a href="#">FormType</a> structure). |
|----------|-------------------------------------------------------------------|
- Result** Returns the number of objects in the specified form.
- See Also** [FrmGetObjectPtr](#), [FrmGetObjectId](#)

## FrmGetObjectBounds

- Purpose** Retrieve the bounds of an object given its form and index.
- Declared In** `Form.h`
- Prototype** `void FrmGetObjectBounds (const FormType *formP, UInt16 objIndex, RectangleType *rP)`
- Parameters**
- |                             |                                                                                                                                        |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; formP</code>    | Pointer to the form object ( <a href="#">FormType</a> structure).                                                                      |
| <code>-&gt; objIndex</code> | Index of an object in the form. You can obtain this by using <a href="#">FrmGetObjectIndex</a> .                                       |
| <code>&lt;- rP</code>       | Pointer to a <code>RectangleType</code> structure where the object bounds are returned. The bounds are in window-relative coordinates. |
- Result** Returns nothing. The object's bounds are returned in `r`.
- See Also** [FrmGetObjectPosition](#), [FrmSetObjectPosition](#)

## FrmGetObjectId

- Purpose** Return the ID of the specified object.
- Declared In** `Form.h`
- Prototype** `UInt16 FrmGetObjectId (const FormType *formP, UInt16 objIndex)`
- Parameters**
- |                          |                                                                   |
|--------------------------|-------------------------------------------------------------------|
| <code>-&gt; formP</code> | Pointer to the form object ( <a href="#">FormType</a> structure). |
|--------------------------|-------------------------------------------------------------------|

## Forms

### Form Functions

---

-> objIndex      Index of an object in the form. You can obtain this by using [FrmGetObjectIndex](#).

**Result**      Returns the ID number of an object or frmInvalidObjectId if the objIndex parameter is invalid.

**See Also**      [FrmGetObjectPtr](#)

## FrmGetObjectIndex

**Purpose**      Return the index of an object in the form's objects list.

**Declared In**      Form.h

**Prototype**      UInt16 FrmGetObjectIndex (const FormType \*formP, UInt16 objID)

**Parameters**      -> formP      Pointer to the form object ([FormType](#) structure).  
-> objID      ID of an object in the form.

**Result**      Returns the index of the specified object (the index of the first object is 0), or frmInvalidObjectId if the supplied object ID is invalid.

**Comments**      Bitmaps use a different mechanism for IDs than the rest of the form objects. When finding a bitmap with FrmGetObjectIndex, you need to pass the bitmap's resource ID, not the ID of the form bitmap object. (Passing the ID of the form bitmap object may or may not give you the right object back, depending on how you created the objects.)

This means that if you've got the same bitmap in two different form bitmap objects on the same form, you won't be able to use FrmGetObjectIndex to get at the second one; it'll always return the first.

**See Also**      [FrmGetObjectPtr](#), [FrmGetObjectId](#)

## FrmGetObjectIndexFromPtr

- Purpose** Return an object's index.
- Declared In** `Form.h`
- Prototype**  
`UInt16 FrmGetObjectIndexFromPtr  
(const FormType *formP, void *objP)`
- Parameters**
- |                          |                                         |
|--------------------------|-----------------------------------------|
| <code>-&gt; formP</code> | Pointer to a <a href="#">FormType</a> . |
| <code>-&gt; objP</code>  | Pointer to an object.                   |
- Result** Returns the object's index. `frmInvalidObjectId` is returned if `objP` is not associated with the form.
- Comments** Many form functions ([FrmGetObjectType](#), [FrmHideObject](#), and [FrmGetObjectBounds](#), for example) take an object index as one of their arguments. The most common way to get an object's index is to call [FrmGetObjectIndex](#). `FrmGetObjectIndex` takes a form ID and returns the form object's index. This is the routine one should use in most cases, because the application usually knows the object ID. However, gadgets and specifically extended gadgets, have APIs with callbacks that pass back the gadget pointer and not the ID. In those cases, the only way to get the object index (so one can use the `FrmGetObject*` APIs) is to use `FrmGetObjectIndexFromPtr`.
- If you need the same functionality on pre-Palm OS 4.0 systems then you can accomplish the same thing with the following code snippet.

---

```
UInt16 index;  
UInt16 objIndex = frmInvalidObjectId;  
UInt16 numObjects = FrmGetNumberOfObjects(formP)  
for (index = 0; index < numObjects; index++) {  
    if (FrmGetObjectPtr(index) == myObjPtr) {  
        // Found it  
        objIndex = index;  
        break;  
    }  
}
```

---

## Forms

### Form Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## FrmGetObjectPosition

**Purpose** Return the coordinates of the specified object relative to the form.

**Declared In** `Form.h`

**Prototype** `void FrmGetObjectPosition (const FormType *formP, UInt16 objIndex, Coord *x, Coord *y)`

**Parameters**

|             |                                                                                                                                  |
|-------------|----------------------------------------------------------------------------------------------------------------------------------|
| -> formP    | Pointer to the form object ( <a href="#">FormType</a> structure).                                                                |
| -> objIndex | Index of an object in the form. You can obtain this by using <a href="#">FrmGetObjectIndex</a> .                                 |
| <- x, y     | Pointers where the window-relative x and y positions of the object are returned. These locate the top-left corner of the object. |

**Result** Returns nothing.

**See Also** [FrmGetObjectBounds](#), [FrmSetObjectPosition](#)

## FrmGetObjectPtr

**Purpose** Return a pointer to the data structure of an object in a form.

**Declared In** `Form.h`

**Prototype** `void *FrmGetObjectPtr (const FormType *formP, UInt16 objIndex)`

**Parameters**

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| -> formP | Pointer to the form object ( <a href="#">FormType</a> structure). |
|----------|-------------------------------------------------------------------|

-> objIndex      Index of an object in the form. You can obtain this by using [FrmGetObjectIndex](#).

**Result**      Returns a pointer to an object in the form.

**See Also**      [FrmGetObjectId](#)

## **FrmGetObjectType**

**Purpose**      Return the type of an object.

**Declared In**      Form.h

**Prototype**      FormObjectKind FrmGetObjectType  
(const FormType \*formP, UInt16 objIndex)

**Parameters**      -> formP      Pointer to the form object ([FormType](#) structure).

-> objIndex      Index of an object in the form. You can obtain this by using [FrmGetObjectIndex](#).

**Result**      Returns FormObjectKind of the item specified. See [FormObjectKind](#).

## **FrmGetTitle**

**Purpose**      Return a pointer to the title string of a form.

**Declared In**      Form.h

**Prototype**      const Char \*FrmGetTitle (const FormType \*formP)

**Parameters**      -> formP      Pointer to the form object ([FormType](#) structure).

**Result**      Returns a pointer to title string, or NULL if there is no title string or there is an error finding it.

## Forms

### Form Functions

---

**Comments** This is a pointer to the internal structure itself, **not** to a copy.

**See Also** [FrmCopyTitle](#), [FrmSetTitle](#)

## FrmGetWindowHandle

**Purpose** Return the window handle of a form.

**Declared In** `Form.h`

**Prototype**  
`WinHandle FrmGetWindowHandle  
(const FormType *formP)`

**Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).

**Result** Returns the handle of the memory block that contains the form data structure. Since the form structure begins with the [WindowType](#), this is also a `WinHandle`.

## FrmGotoForm

**Purpose** Send a [frmCloseEvent](#) to the current form; send a [frmLoadEvent](#) and a [frmOpenEvent](#) to the specified form.

**Declared In** `Form.h`

**Prototype**  
`void FrmGotoForm (UInt16 formId)`

**Parameters** `-> formId` ID of the form to display.

**Result** Returns nothing.

**Comments** The default form event handler ([FrmHandleEvent](#)) erases and disposes of a form when it receives a [frmCloseEvent](#).

**Table 11.1 FrmHandleEvent Actions**

| <b>When FrmHandleEvent receives...</b>                                    | <b>FrmHandleEvent performs these actions...</b>                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">ctlEnterEvent</a>                                             | Passes the event and a pointer to the object the event occurred in to <a href="#">CtlHandleEvent</a> . The object pointer is obtained from the event data. If the control is part of an exclusive control group, it deselects the currently selected control of the group first.                                                                                                     |
| <a href="#">ctlRepeatEvent</a>                                            | Passes the event and a pointer to the object the event occurred in to <a href="#">CtlHandleEvent</a> . The object pointer is obtained from the event data.                                                                                                                                                                                                                           |
| <a href="#">ctlSelectEvent</a>                                            | Checks if the control is a Popup Trigger Control. If it is, the list associated with the popup trigger is displayed until the user makes a selection or touches the pen outside the bounds of the list. If a selection is made, a <a href="#">popSelectEvent</a> is added to the event queue.                                                                                        |
| <a href="#">fldEnterEvent</a> or<br><a href="#">fldHeightChangedEvent</a> | Checks if a field object or a table object has the focus and passes the event to the appropriate handler ( <a href="#">FldHandleEvent</a> or <a href="#">TblHandleEvent</a> ). The table object is also a container object, which may contain a field object. If <a href="#">TblHandleEvent</a> receives a field event, it passes the event to the field object contained within it. |
| <a href="#">frmCloseEvent</a>                                             | Erases the form and releases any memory allocated for it.                                                                                                                                                                                                                                                                                                                            |
| <a href="#">frmGadgetEnterEvent</a>                                       | Passes the event to the gadget's callback function if the gadget has one. See <a href="#">FormGadgetHandlerType</a> .                                                                                                                                                                                                                                                                |
| <a href="#">frmGadgetMiscEvent</a>                                        | Passes the event to the gadget's callback function if the gadget has one. See <a href="#">FormGadgetHandlerType</a> .                                                                                                                                                                                                                                                                |
| <a href="#">frmTitleEnterEvent</a>                                        | Tracks the pen until it is lifted. If it is lifted within the bounds of the form title, adds a <a href="#">frmTitleSelectEvent</a> event to the event queue.                                                                                                                                                                                                                         |

**Table 11.1 FrmHandleEvent Actions (*continued*)**

| When FrmHandleEvent receives...                                              | FrmHandleEvent performs these actions...                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">frmTitleSelectEvent</a>                                          | Adds a <a href="#">keyDownEvent</a> with the vchrMenu character to the event queue.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <a href="#">frmUpdateEvent</a>                                               | Calls <a href="#">FrmDrawForm</a> to redraw the form.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <a href="#">keyDownEvent</a>                                                 | Passes the event to the handler for the object that has the focus. If no object has the focus, the event is ignored.                                                                                                                                                                                                                                                                                                                                                                                          |
| <a href="#">lstEnterEvent</a>                                                | Passes the event and a pointer to the object the event occurred in to <a href="#">LstHandleEvent</a> . The object pointer is obtained from the event data.                                                                                                                                                                                                                                                                                                                                                    |
| <a href="#">menuCmdBarOpenEvent</a>                                          | Checks if a field object or a table object has the focus and passes the event to the appropriate handler ( <a href="#">FldHandleEvent</a> or <a href="#">TblHandleEvent</a> ), broadcasts the notification <a href="#">sysNotifyMenuCmdBarOpenEvent</a> , and then displays the command toolbar.                                                                                                                                                                                                              |
| <a href="#">menuEvent</a>                                                    | Checks if the menu command is one of the system edit menu commands. The system provides a standard edit menu that contains the commands Undo, Cut, Copy, Paste, Select All, and Keyboard. <a href="#">FrmHandleEvent</a> responds to these commands.                                                                                                                                                                                                                                                          |
| <a href="#">penDownEvent</a> ; pen position in the bounds of the form object | Checks the list of objects contained by the form to determine if the pen is within the bounds of one. If it is, the appropriate handler is called to handle the event, for example, if the pen is in a control, <a href="#">CtlHandleEvent</a> is called. If the pen isn't within the bounds of an object, the event is ignored by the form. If the pen is within the bounds of the help icon, it is tracked until it is lifted, and if it's still within the help icon bounds, the help dialog is displayed. |
| <a href="#">popSelectEvent</a>                                               | Sets the label of the popup trigger to the current selection of the popup list.                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Forms

### Form Functions

---

**Table 11.1 FrmHandleEvent Actions (*continued*)**

| When FrmHandleEvent receives...                                 | FrmHandleEvent performs these actions...                                                                                                                   |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">sclEnterEvent</a> or <a href="#">sclRepeatEvent</a> | Passes the event and a pointer to the object the event occurred in to <a href="#">SclHandleEvent</a> .                                                     |
| <a href="#">tblEnterEvent</a>                                   | Passes the event and a pointer to the object the event occurred in to <a href="#">TblHandleEvent</a> . The object pointer is obtained from the event data. |

---

**Compatibility** FrmHandleEvent only handles frmTitleSelectEvent, menuCmdBarOpenEvent, frmGadgetEnterEvent, and frmGadgetMiscEvent if [3.5 New Feature Set](#) is present. If [5.0 New Feature Set](#) is present, this function should be considered “System Use Only”; applications should do what they can to avoid using it.

**See Also** [FrmDispatchEvent](#)

## FrmHelp

**Purpose** Display the specified help message until the user taps the Done button in the help dialog.

**Declared In** Form.h

**Prototype** void FrmHelp (UInt16 helpMsgId)

**Parameters** -> helpMsgId      Resource ID of help message string.

**Result** Returns nothing.

**Comments** The help message is displayed in a modal dialog that supports scrolling the text if necessary.

## FrmHideObject

- Purpose** Erase the specified object and set its attribute data (`usable` bit) so that it does not redraw or respond to the pen.
- Declared In** `Form.h`
- Prototype** `void FrmHideObject (FormType *formP,  
UInt16 objIndex)`
- Parameters**
- |                          |                                                                                                  |
|--------------------------|--------------------------------------------------------------------------------------------------|
| -> <code>formP</code>    | Pointer to the form object ( <a href="#">FormType</a> structure).                                |
| -> <code>objIndex</code> | Index of an object in the form. You can obtain this by using <a href="#">FrmGetObjectIndex</a> . |
- Result** Returns nothing.
- Compatibility** Prior to OS version 3.2, this function did not set the `usable` bit of the object attribute data to `false`. On an OS version prior to 3.2 you can work around this bug by directly setting this bit to `false` yourself.
- On versions of Palm OS prior to 3.5 this function doesn't affect lists or tables. On Palm OS 3.5 it operates correctly on lists but doesn't have any effect on tables. On Palm OS 4.0 it operates correctly on both lists and tables.
- If [3.5 New Feature Set](#) is present and the object is an extended gadget, this function calls the gadget's callback with `formGadgetEraseCmd`. See [FormGadgetHandlerType](#).
- See Also** [FrmShowObject](#)

## Forms

### Form Functions

---

## FrmlInitForm

- Purpose** Load and initialize a form resource.
- Declared In** `Form.h`
- Prototype** `FormType *FrmlInitForm (UInt16 rscID)`
- Parameters** `-> rscID` Resource ID of the form.
- Result** Returns a pointer to the form data structure.  
When using debug ROMs, `FrmlInitForm` displays an error message if the form has already been initialized.
- Comments** This function does not affect the display (use [FrmlDrawForm](#) to draw the form) nor make the form active (use [FrmlSetActiveForm](#) to make it active).  
For each initialized form, you must call `FrmlDeleteForm` to release the form memory when you are done with the form. Alternatively, you can free the active form by calling `FrmlReturnToForm`.
- See Also** [FrmlDoDialog](#), [FrmlDeleteForm](#), [FrmlReturnToForm](#)

## FrmNewBitmap

| <code>&lt;-&gt; formPP</code> | Pointer to a pointer to the form in which the new bitmap is installed. This value is not a handle; that is, the old <code>formPP</code> value is not necessarily valid after this function returns because the form may be moved in memory. In subsequent calls, always use the new <code>formPP</code> value returned by this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                               |                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                             |                          |                                                                                                                          |                      |                                                                                                                        |                      |                                                                                                                      |
| <code>-&gt; ID</code>         | Symbolic ID of the bitmap, specified by the developer. By convention, this ID should match the resource ID (not mandatory).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                               |                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                             |                          |                                                                                                                          |                      |                                                                                                                        |                      |                                                                                                                      |
| <code>-&gt; rscID</code>      | Numeric value identifying the resource that provides the bitmap. This value must be unique within the application scope.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                               |                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                             |                          |                                                                                                                          |                      |                                                                                                                        |                      |                                                                                                                      |
| <code>-&gt; x</code>          | Horizontal coordinate of the upper-left corner of the bitmap's boundaries, relative to the window in which it appears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                               |                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                             |                          |                                                                                                                          |                      |                                                                                                                        |                      |                                                                                                                      |
| <code>-&gt; y</code>          | Vertical coordinate of the upper-left corner of the bitmap's boundaries, relative to the window in which it appears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                               |                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                             |                          |                                                                                                                          |                      |                                                                                                                        |                      |                                                                                                                      |
| <b>Result</b>                 | Returns a pointer to the new bitmap, or 0 if the call did not succeed. The most common cause of failure is lack of memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                               |                                                                                                                                                                                                                                                                                                                                          |                       |                                                                                                                             |                          |                                                                                                                          |                      |                                                                                                                        |                      |                                                                                                                      |

Only modal dialogs can have help resources. |
| -> formID          | Symbolic ID of the form, specified by the developer. By convention, this ID should match the resource ID (not mandatory).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> titleStrP       | Pointer to a string that is the title of the form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> x               | Horizontal coordinate of the upper-left corner of the form's boundaries, relative to the window in which it appears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> y               | Vertical coordinate of the upper-left corner of the form's boundaries, relative to the window in which it appears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> width           | Width of the form, expressed in pixels. Valid values are 1 -160.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> height          | Height of the form, expressed in pixels. Valid values are 1 -160.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> modal           | true specifies that the form ignores pen events outside its boundaries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> defaultButton   | Symbolic ID of the button that provides the form's default action, specified by the developer.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |
| -> helpRscID       | Symbolic ID of the resource that provides the form's online help, specified by the developer. Only modal dialogs can have help resources.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |           |                                                                                                                           |              |                                                    |      |                                                                                                                      |      |                                                                                                                    |          |                                                                  |           |                                                                   |          |                                                                         |                  |                                                                                                |              |                                                                                                                                           |

-> menuRscID      Symbolic ID of the resource that provides the form's menus, specified by the developer.

**Result**      Returns a pointer to the new form object, or 0 if the call did not succeed. The most common cause of failure is lack of memory.

**Compatibility**      Implemented only if [3.0 New Feature Set](#) is present.

**See Also**      [FrmValidatePtr](#), [WinValidateHandle](#), [FrmRemoveObject](#)

## **FrmNewGadget**

**Purpose**      Create a new gadget dynamically and install it in the specified form.

**Declared In**      Form.h

**Prototype**      `FormGadgetType *FrmNewGadget (FormType **formPP, UInt16 id, Coord x, Coord y, Coord width, Coord height)`

**Parameters**      <-> formPP      Pointer to a pointer to the form in which the new gadget is installed. This value is not a handle; that is, the old formPP value is not necessarily valid after this function returns because the form may be moved in memory. In subsequent calls, always use the new formPP value returned by this function.

-> id      Symbolic ID of the gadget, specified by the developer. By convention, this ID should match the resource ID (not mandatory).

-> x      Horizontal coordinate of the upper-left corner of the gadget's boundaries, relative to the window in which it appears.

-> y      Vertical coordinate of the upper-left corner of the gadget's boundaries, relative to the window in which it appears.

## Forms

### Form Functions

---

-> width            Width of the gadget, expressed in pixels. Valid values are 1 - 160.

-> height           Height of the gadget, expressed in pixels. Valid values are 1 - 160.

**Result**           Returns a pointer to the new gadget object or 0 if the call did not succeed. The most common cause of failure is lack of memory.

**Comments**        A gadget is a custom user interface object. For more information, see "[Gadget Resource](#)" on page 50.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

**See Also**          [FrmRemoveObject](#)

## FrmNewGsi

**Purpose**            Create a new Graffiti shift indicator dynamically and install it in the specified form.

**Declared In**      Form.h

**Prototype**        FrmGraffitiStateType \*FrmNewGsi  
(FormType \*\*formPP, Coord x, Coord y)

**Parameters**      <-> formPP            Pointer to a pointer to the form in which the new Graffiti shift indicator is installed. This value is not a handle; that is, the old formPP value is not necessarily valid after this function returns because the form may be moved in memory. In subsequent calls, always use the new formPP value returned by this function.

-> x                Horizontal coordinate of the upper-left corner of the Graffiti shift indicator's boundaries, relative to the window in which it appears.

-> y                      Vertical coordinate of the upper-left corner of the Graffiti shift indicator's boundaries, relative to the window in which it appears.

**Result**                Returns a pointer to the new gadget object or 0 if the call did not succeed. The most common cause of failure is lack of memory.

**Comments**            In normal operation, the Graffiti shift indicator is drawn in the lower-right portion of the screen when the user enters the shift keystroke. You use this function if the Graffiti shift indicator needs to be drawn in a nonstandard location. For example, the form manager uses it to draw the shift indicator in a custom alert dialog that contains a text field ([FrmCustomResponseAlert](#)).

**Compatibility**        Implemented only if [3.5 New Feature Set](#) is present.

**See Also**              [FrmRemoveObject](#)

## **FrmNewLabel**

**Purpose**                Create a new label object dynamically and install it in the specified form.

**Declared In**          Form.h

**Prototype**            `FormLabelType *FrmNewLabel (FormType **formPP, UInt16 ID, const Char *textP, Coord x, Coord y, FontID font)`

**Parameters**          <-> formPP            Pointer to a pointer to the form in which the new label is installed. This value is not a handle; that is, the old formPP value is not necessarily valid after this function returns because the form may be moved in memory. In subsequent calls, always use the new formPP value returned by this function.

## Forms

### Form Functions

---

|          |                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------|
| -> ID    | Symbolic ID of the label, specified by the developer. By convention, this ID should match the resource ID (not mandatory). |
| -> textP | Pointer to a string that provides the label text. This string is copied into the label structure.                          |
| -> x     | Horizontal coordinate of the upper-left corner of the label's boundaries, relative to the window in which it appears.      |
| -> y     | Vertical coordinate of the upper-left corner of the label's boundaries, relative to the window in which it appears.        |
| -> font  | Font with which to draw the label text.                                                                                    |

**Result** Returns a pointer to the new label object or 0 if the call did not succeed. The most common cause of failure is lack of memory.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [CtlValidatePointer](#), [FrmRemoveObject](#)

## FrmPointInTitle

**Purpose** Check if a coordinate is within the bounds of the form's title.

**Declared In** `Form.h`

**Prototype** `Boolean FrmPointInTitle (const FormType *formP, Coord x, Coord y)`

**Parameters**

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| -> formP | Pointer to the form object ( <a href="#">FormType</a> structure). |
| -> x, y  | Window-relative x and y coordinates.                              |

**Result** Returns `true` if the specified coordinate is in the form's title.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## FrmPopupForm

- Purpose** Queues a [frmLoadEvent](#) and a [frmOpenEvent](#) for the specified form.
- Declared In** `Form.h`
- Prototype** `void FrmPopupForm (UInt16 formId)`
- Parameters** `-> formID` Resource ID of form to open.
- Result** Returns nothing.
- Comments** This routine differs from [FrmGotoForm](#) in that the current form is not closed. You can call [FrmReturnToForm](#) to close a form opened by `FrmPopupForm`.

## FrmRemoveObject

- Purpose** Remove the specified object from the specified form.
- Declared In** `Form.h`
- Prototype** `Err FrmRemoveObject (FormType **formPP, UInt16 objIndex)`
- Parameters**
- |                               |                                                                                                                                                                                                                                                                                                        |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; formPP</code> | Pointer to a pointer to the form from which this function removes an object. This value is not a handle; that is, the old <code>formPP</code> value is not necessarily valid after this function returns. In subsequent calls, always use the new <code>formPP</code> value returned by this function. |
| <code>-&gt; objIndex</code>   | The object to remove, specified as an index into the list of objects installed in the form. You can use the <a href="#">FrmGetObjectIndex</a> function to discover this value.                                                                                                                         |
- Result** Returns 0 if no error.

## Forms

### Form Functions

---

**Comments** You can use this function to remove any form object (a bitmap, control, list, and so on) and free the memory allocated to it within the form data structure. The data structures for most form objects are embedded within the form data structure memory chunk. This function frees that memory and moves the other objects, if necessary, to close up the memory “hole” and decrease the size of the form chunk.

Note that this function does not free memory outside the form data structure that may be allocated to an object, such as the memory allocated to the string in an editable field object.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FrmNewBitmap](#), [FrmNewForm](#), [FrmNewGadget](#), [FrmNewLabel](#), [CtlNewControl](#), [FldNewField](#), [LstNewList](#)

## FrmRestoreActiveState

**Purpose** Macro that restores the active window and form state.

**Declared In** `Form.h`

**Prototype** `FrmRestoreActiveState (stateP)`

**Parameters** `-> stateP` A pointer to the `FormActiveStateType` structure that you passed to `FrmSaveActiveState` when you saved the state.

**Result** Returns zero on success.

**Comments** Use this function to restore the state of displayed forms to the state that existed before you dynamically showed a new modal form. You must have previously called [FrmSaveActiveState](#) to save the state.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## FrmReturnToForm

- Purpose** Erase and delete the currently active form and make the specified form the active form.
- Declared In** `Form.h`
- Prototype** `void FrmReturnToForm (UInt16 formId)`
- Parameters** `-> formID` Resource ID of the form to return to.
- Result** Returns nothing.
- Comments** It is assumed that the form being returned to is already loaded into memory and initialized. Passing a form ID of 0 returns to the first form in the window list, which is the last form to be loaded.
- `FrmReturnToForm` does not generate a `frmCloseEvent` when called from a modal form's event handler. It assumes that you have already handled cleaning up your form's variables since you are explicitly calling `FrmReturnToForm`.
- See Also** [FrmGotoForm](#), [FrmPopupForm](#)

## Forms

### Form Functions

---

## FrmSaveActiveState

- Purpose** Macro that saves the active window and form state.
- Declared In** `Form.h`
- Prototype** `FrmSaveActiveState (stateP)`
- Parameters** `<-> stateP` A pointer to a `FormActiveStateType` structure that is used to save the state. Pass the same pointer to `FrmRestoreActiveState` to restore the state. Treat the structure like a black box; that is, don't attempt to read it or write to it.
- Result** Returns zero on success.
- Comments** Use this function to save the state of displayed forms before dynamically showing a new modal form. Call [FrmRestoreActiveState](#) to restore the state after you remove the modal form.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## FrmSaveAllForms

- Purpose** Send a [frmSaveEvent](#) to all open forms.
- Declared In** `Form.h`
- Prototype** `void FrmSaveAllForms (void)`
- Parameters** None.
- Result** Returns nothing.
- See Also** [FrmCloseAllForms](#)

## FrmSetActiveForm

- Purpose** Set the active form. All input (key and pen) is directed to the active form and all drawing occurs there.
- Declared In** `Form.h`
- Prototype** `void FrmSetActiveForm (FormType *formP)`
- Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).
- Result** Returns nothing.
- Comments** A [penDownEvent](#) outside the form but within the display area is ignored.
- Compatibility** In Palm OS releases earlier than 3.5, this function generated a [winEnterEvent](#) for the new form immediately following the [winExitEvent](#) for the old form. Starting in Palm OS 3.5, `FrmSetActiveForm` does not generate the `winEnterEvent`. The `winEnterEvent` does not occur until the newly active form is drawn.
- See Also** [FrmGetActiveForm](#)

## FrmSetCategoryLabel

- Purpose** Set the category label displayed on the title line of a form. If the form's `visible` attribute is set, redraw the label.
- Declared In** `Form.h`
- Prototype** `void FrmSetCategoryLabel (const FormType *formP, UInt16 objIndex, Char *newLabel)`
- Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).

## FrmSetControlValue

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |          |                                                                   |             |                                                                                                    |             |                                                                                                                                                                                                   |

| <b>Comments</b>    | This function works only with graphical controls, sliders, push buttons, and check boxes. If you set the value of any other type of control, the behavior is undefined.                                                                                                                                                                                                                                                                                                                                   |          |                                                                   |             |                                                                                                    |             |                                                                                                                                                                                                   |
| <b>See Also</b>    | <a href="#">FrmGetControlValue</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |          |                                                                   |             |                                                                                                    |             |                                                                                                                                                                                                   |

## Forms

### Form Functions

---

## FrmSetEventHandler

- Purpose** Registers the event handler callback routine for the specified form.
- Declared In** `Form.h`
- Prototype**  
`void FrmSetEventHandler (FormType *formP,  
FormEventHandlerType *handler)`
- Parameters**
- |            |                                                                                    |
|------------|------------------------------------------------------------------------------------|
| -> formP   | Pointer to the form object ( <a href="#">FormType</a> structure).                  |
| -> handler | Address of the form event handler function, <a href="#">FormEventHandlerType</a> . |
- Result** Returns nothing.
- Comments** [FrmDispatchEvent](#) calls this handler whenever it receives an event for a specific form.
- `FrmSetEventHandler` must be called right after a form resource is loaded. The callback routine it registers is the mechanism for dispatching events to an application. The tutorial explains how to use callback routines.

## FrmSetFocus

- Purpose** Set the focus of a form to the specified object.
- Declared In** `Form.h`
- Prototype**  
`void FrmSetFocus (FormType *formP,  
UInt16 fieldIndex)`
- Parameters**
- |          |                                                                   |
|----------|-------------------------------------------------------------------|
| -> formP | Pointer to the form object ( <a href="#">FormType</a> structure). |
|----------|-------------------------------------------------------------------|

-> fieldIndex      Index of the object to get the focus in the form. You can obtain this by using [FrmGetObjectIndex](#). You can pass the constant noFocus so that no object has the focus.

**Result**      Returns nothing.

**Comments**      You can set the focus to a field or table object. If the focus is set to a field object, this function turns on the insertion point in the field by calling [FldGrabFocus](#) internally.

**See Also**      [FrmGetFocus](#)

## **FrmSetGadgetData**

**Purpose**      Store a data value in the data field of the gadget object.

**Declared In**      Form.h

**Prototype**      void FrmSetGadgetData (FormType \*formP,  
                          UInt16 objIndex, const void \*data)

**Parameters**

-> formP              Pointer to the form object ([FormType](#) structure).

-> objIndex            Index of an object in the form. You can obtain this by using [FrmGetObjectIndex](#).

-> data                Application-defined value. This value is stored into the data field of the gadget data structure ([FormGadgetType](#)).

**Result**      Returns nothing.

**Comments**      Gadget objects provide a way for an application to attach custom gadgetry to a form. Typically, the data field of a gadget object contains a pointer to the custom object's data structure.

**See Also**      [FrmGetGadgetData](#), [FrmSetGadgetHandler](#)

## FrmSetGadgetHandler

|                      |                                                                                                                                                                                                                                                                                                                                                                                       |          |                                                                   |             |                                                                                                        |          |                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-------------------------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------|----------|-------------------------------------------------------------------------------|
| <b>Purpose</b>       | Registers the gadget event handler callback routine for the specified gadget on the specified form.                                                                                                                                                                                                                                                                                   |          |                                                                   |             |                                                                                                        |          |                                                                               |
| <b>Declared In</b>   | Form.h                                                                                                                                                                                                                                                                                                                                                                                |          |                                                                   |             |                                                                                                        |          |                                                                               |
| <b>Prototype</b>     | <pre>void FrmSetGadgetHandler (FormType *formP,<br/>UInt16 objIndex, FormGadgetHandlerType *attrP)</pre>                                                                                                                                                                                                                                                                              |          |                                                                   |             |                                                                                                        |          |                                                                               |

| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                      |          |                                                                   |             |                                                                                                        |          |                                                                               |
| <b>Comments</b>      | This function sets the application-defined function that controls the specified gadget's behavior. This function is called when the gadget needs to be drawn, erased, deleted, or needs to handle an event.                                                                                                                                                                           |          |                                                                   |             |                                                                                                        |          |                                                                               |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                   |          |                                                                   |             |                                                                                                        |          |                                                                               |
| <b>See Also</b>      | <a href="#">FrmGetGadgetData</a> , <a href="#">FrmSetGadgetData</a>                                                                                                                                                                                                                                                                                                                   |          |                                                                   |             |                                                                                                        |          |                                                                               |

## FrmSetMenu

- Purpose** Change a form's menu bar and make the new menu active.
- Declared In** `Form.h`
- Prototype** `void FrmSetMenu (FormType *formP,  
UInt16 menuRscID)`
- Parameters**
- > `formP` Pointer to the form object ([FormType](#) structure).
  - > `menuRscID` Resource ID of the menu.
- Result** Returns nothing.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## FrmSetObjectBounds

- Purpose** Set the bounds or position of an object.
- Declared In** `Form.h`
- Prototype** `void FrmSetObjectBounds (FormType *formP,  
UInt16 objIndex, const RectangleType *bounds)`
- Parameters**
- > `formP` Pointer to the form object ([FormType](#) structure).
  - > `objIndex` Index of an object in the form. You can obtain this by using [FrmGetObjectIndex](#).
  - > `bounds` Window-relative bounds. For the following objects, this sets only the position of the top-left corner: label, bitmap, and Graffiti state indicator.
- Result** Returns nothing.

## Forms

### Form Functions

---

**Comments** Doesn't update the display.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## FrmSetObjectPosition

**Purpose** Set the position of an object.

**Declared In** Form.h

**Prototype** void FrmSetObjectPosition (FormType \*formP,  
UInt16 objIndex, Coord x, Coord y)

**Parameters**

|             |                                                                                                  |
|-------------|--------------------------------------------------------------------------------------------------|
| -> formP    | Pointer to the form object ( <a href="#">FormType</a> structure).                                |
| -> objIndex | Index of an object in the form. You can obtain this by using <a href="#">FrmGetObjectIndex</a> . |
| -> x        | Window-relative horizontal coordinate.                                                           |
| -> y        | Window-relative vertical coordinate.                                                             |

**Result** Returns nothing.

**See Also** [FrmGetObjectPosition](#), [FrmGetObjectBounds](#)

## FrmSetTitle

**Purpose** Set the title of a form. If the form is visible, draw the new title.

**Declared In** Form.h

**Prototype** void FrmSetTitle (FormType \*formP,  
Char \*newTitle)

**Parameters**

|          |                                                                   |
|----------|-------------------------------------------------------------------|
| -> formP | Pointer to the form object ( <a href="#">FormType</a> structure). |
|----------|-------------------------------------------------------------------|

-> newTitle      Pointer to the new title string.

**Result**      Returns nothing.

**Comments**      This function draws the title if the form is visible.  
This function saves the pointer passed in newTitle; it does **not** make a copy. The value of newTitle must not be a pointer to a stack-based object.

**Compatibility**      Earlier versions of this function redrew the title without first erasing the old one. This problem was corrected in version 3.0 of Palm OS.

**See Also**      [FrmGetTitle](#), [FrmCopyTitle](#), [FrmCopyLabel](#)

## **FrmShowObject**

**Purpose**      Set a form object as usable. If the form is visible, draw the object.

**Declared In**      Form.h

**Prototype**      void FrmShowObject (FormType \*formP,  
                         UInt16 objIndex)

**Parameters**      -> formP      Pointer to the form object ([FormType](#) structure).  
                     -> objIndex      Index of an object in the form. You can obtain this by using [FrmGetObjectIndex](#).

**Result**      Returns nothing.

**Compatibility**      On versions of Palm OS prior to 3.5 this function doesn't affect lists or tables. On Palm OS 3.5 it operates correctly on lists but doesn't have any effect on tables. On Palm OS 4.0 it operates correctly on both lists and tables.

## Forms

### Form Functions

---

If [3.5 New Feature Set](#) is present and the object is an extended gadget, this function calls the gadget's callback with `formGadgetDrawCmd`. See [FormGadgetHandlerType](#).

**See Also** [FrmHideObject](#)

## FrmUpdateForm

**Purpose** Send a [frmUpdateEvent](#) to the specified form.

**Declared In** `Form.h`

**Prototype** `void FrmUpdateForm (UInt16 formId,  
UInt16 updateCode)`

**Parameters**

|                            |                                                                                                                                                                                         |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>formId</code>     | Resource ID of form to update.                                                                                                                                                          |
| -> <code>updateCode</code> | An application-defined code that can be used to indicate what needs to be updated. Specify the code <code>frmRedrawUpdateCode</code> to indicate that the whole form should be redrawn. |

**Result** Returns nothing.

**Comments** If the `frmUpdateEvent` posted by this function is handled by the default form event handler, [FrmHandleEvent](#), the `updateCode` parameter is ignored. `FrmHandleEvent` always redraws the form.

If you handle the `frmUpdateEvent` in a custom event handler, you can use the `updateCode` parameter any way you want. For example, you might use it to indicate that only a certain part of the form needs to be redrawn. If you do handle the `frmUpdateEvent`, be sure to return `true` from your event handler so that the default form handler does not also redraw the whole form.

If you do handle the `frmUpdateEvent` in a custom event handler, be sure to handle the case where `updateCode` is set to `frmRedrawUpdateCode`, and redraw the whole form. This event (and code) is sent by the system when the whole form needs to be redrawn because the display needs to be refreshed.

## FrmUpdateScrollers

- Purpose** Visually update (show or hide) the field scroll arrow buttons.
- Declared In** `Form.h`
- Prototype**  
`void FrmUpdateScrollers (FormType *formP,  
UInt16 upIndex, UInt16 downIndex,  
Boolean scrollableUp, Boolean scrollableDown)`
- Parameters**
- > `formP` Pointer to the form object ([FormType](#) structure).
  - > `upIndex` Index of the up-scroller button. You can obtain this by using [FrmGetObjectIndex](#).
  - > `downIndex` Index of the down-scroller button. You can obtain this by using [FrmGetObjectIndex](#).
  - > `scrollableUp` Set to `true` to make the up scroll arrow active (shown), or `false` to hide it.
  - > `scrollableDown` Set to `true` to make the down scroll arrow active (shown), or `false` to hide it.
- Result** Returns nothing.

## FrmValidatePtr

- Purpose** Return `true` if the specified pointer references a valid form.
- Declared In** `Form.h`
- Prototype**  
`Boolean FrmValidatePtr (const FormType *formP)`
- Parameters**
- > `formP` Pointer to be tested.
- Result** Returns `true` if the specified pointer is a non-NULL pointer to an object having a valid form structure.

## Forms

### *Form Functions*

---

**Comments** This function is intended for debugging purposes only. Do not include it in released code.

To distinguish between a window and a form in released code, instead of using this function, look at the flag `windowFlags.dialog` in the [WindowType](#) structure. This flag is `true` if the window is a form.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## FrmVisible

**Purpose** Return `true` if the form is visible (is drawn).

**Declared In** `Form.h`

**Prototype** `Boolean FrmVisible (const FormType *formP)`

**Parameters** `-> formP` Pointer to the form object ([FormType](#) structure).

**Result** Returns `true` if the form is visible; `false` if it is not visible.

**See Also** [FrmDrawForm](#), [FrmEraseForm](#)

## Application-Defined Functions

### FormCheckResponseFuncType

**Purpose** Callback function for [FrmCustomResponseAlert](#).

**Declared In** `Form.h`

**Prototype** `Boolean FormCheckResponseFuncType (Int16 button, Char *attempt)`

**Parameters** `-> button` The ID of the button that the user tapped.

## Forms

### Application-Defined Functions

---

-> attempt            The string that the user entered in the alert dialog.

**Result**            Return `true` if the dialog should be dismissed. Return `false` if the dialog should not be dismissed.

**Comments**        This function is called at these times during the `FrmCustomResponseAlert` routine:

- At the beginning of `FrmCustomResponseAlert`, this function is called with a button ID of `frmResponseCreate`. This constant indicates that the dialog is about to be displayed, and your function should perform any necessary initialization. For example, on a Japanese system, a password dialog might need to disable the Japanese FEP. So it would call `TsmSetFepMode(NULL, tsmFepModeOff)` in this function.
- When the user has tapped a button on the dialog. The function should process the `attempt` string. If the string is valid input, the function should return `true`. If not, it should return `false` to give the user a chance to re-enter the string.
- At the end of `FrmCustomResponseAlert`, this function is called with a button ID of `frmResponseQuit`. This gives the callback a chance to perform any cleanup, such as re-enabling the Japanese FEP.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

## FormEventHandlerType

|                    |                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The event handler callback routine for a form.                                                                                                                                                                                                                                                   |
| <b>Declared In</b> | Form.h                                                                                                                                                                                                                                                                                           |
| <b>Prototype</b>   | Boolean FormEventHandlerType (EventType *eventP)                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | -> eventP            Pointer to the form event ( <a href="#">FormType</a> structure).                                                                                                                                                                                                            |
| <b>Result</b>      | Must return true if this routine handled the event, otherwise false.                                                                                                                                                                                                                             |
| <b>Comments</b>    | <p><a href="#">FrmDispatchEvent</a> calls this handler whenever it receives an event for the form.</p> <p>This callback routine is the mechanism for dispatching events to particular forms in an application. The callback is registered by the routine <a href="#">FrmSetEventHandler</a>.</p> |

## FormGadgetHandlerType

|                    |                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The event handler callback for an extended gadget.                                                                                                                                                          |
| <b>Declared In</b> | Form.h                                                                                                                                                                                                      |
| <b>Prototype</b>   | Boolean (FormGadgetHandlerType)<br>(struct FormGadgetTypeInCallback *gadgetP,<br>UInt16 cmd, void *paramP)                                                                                                  |
| <b>Parameters</b>  | -> gadgetP            Pointer to the gadget structure. See <a href="#">FormGadgetType</a> .                                                                                                                 |
|                    | -> cmd                A constant that specifies what action the handler should take. This can be one of the following:<br><br>formGadgetDeleteCmd<br>Sent by <a href="#">FrmDeleteForm</a> to indicate that |

## Forms

### Application-Defined Functions

---

the gadget is being deleted and must clean up any memory it has allocated or perform other cleanup tasks.

`formGadgetDrawCmd`

Sent by [FrmDrawForm](#) and [FrmShowObject](#) to indicate that the gadget must be drawn or redrawn.

`formGadgetEraseCmd`

Sent by [FrmHideObject](#) to indicate that the gadget is going to be erased.

`FrmHideObject` clears the `visible` and `usable` flags for you. If you return `false`, it also calls `WinEraseRectangle` to erase the gadget's bounds.

`formGadgetHandleEventCmd`

Sent by [FrmHandleEvent](#) to indicate that a gadget event has been received. The `paramP` parameter contains the pointer to the `EventType` structure.

-> `paramP`

NULL except if `cmd` is `formGadgetHandleEventCmd`. In that case, this parameter holds the pointer to the `EventType` structure containing the event.

**Result** Return `true` if the event was handed successfully; `false` otherwise.

**Comments** If this function performs any drawing in response to the `formGadgetDrawCmd`, it should set the gadget's `visible` attribute flag. (`gadgetP->attr.visible = true`). This flag indicates that the gadget appears on the screen. If you don't set the `visible` flag, the gadget won't be erased when [FrmHideObject](#) is called. (`FrmHideObject` immediately returns if the object's `visible` flag is `false`.)

Note that if the function receives the `formGadgetEraseCmd`, it may simply choose to perform any necessary cleanup and return `false`. If the function returns `false`, `FrmHideObject` erases the

gadget's bounding rectangle. If the function returns `true`, it must erase the gadget area itself.

If this function receives a `frmGadgetHandleEventCmd`, `paramP` points one of two events: [frmGadgetEnterEvent](#) or [frmGadgetMiscEvent](#). The `frmGadgetEnterEvent` is passed when there is a [penDownEvent](#) within the gadget's bounds. This function should track the pen and perform any necessary highlighting. The `frmGadgetMiscEvent` is never sent by the system. Your application may choose to use it if at any point it needs to send data to the extended gadget. In this case, the event has one or both of these fields defined: `selector`, an unsigned integer, and `dataP`, a pointer to data.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

**See Also**        [FrmSetGadgetHandler](#)

## **Forms**

### *Application-Defined Functions*

---

# Graffiti Shift

---

This chapter provides reference material for the Graffiti® Shift facility, declared in the header file `GraffitiShift.h`.

## GraffitiShift Functions

### GsiEnable

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Enable or disable the Graffiti-shift state indicator.                                      |
| <b>Declared In</b> | <code>GraffitiShift.h</code>                                                               |
| <b>Prototype</b>   | <code>void GsiEnable (const Boolean enableIt)</code>                                       |
| <b>Parameters</b>  | <code>enableIt</code> <code>true</code> to enable, <code>false</code> to disable.          |
| <b>Result</b>      | Returns nothing.                                                                           |
| <b>Comments</b>    | Enabling the indicator makes it visible, disabling it makes the insertion point invisible. |

## **GsiEnabled**

- Purpose** Return `true` if the Graffiti-shift state indicator is enabled, or `false` if it's disabled.
- Declared In** `GraffitiShift.h`
- Prototype** `Boolean GsiEnabled (void)`
- Parameters** None.
- Result** `true` if enabled, `false` if not.

## **GsiInitialize**

- Purpose** Initialize the global variables used to manage the Graffiti-shift state indicator.
- Declared In** `GraffitiShift.h`
- Prototype** `void GsiInitialize (void)`
- Parameters** None.
- Result** Returns nothing.

## **GsiSetLocation**

- Purpose** Set the display-relative position of the Graffiti-shift state indicator.
- Declared In** `GraffitiShift.h`
- Prototype** `void GsiSetLocation (const Int16 x, const Int16 y)`
- Parameters** `x, y` Coordinate of left side and top of the indicator.
- Result** Returns nothing.

**Comments** The indicator is not redrawn by this routine.

## **GsiSetShiftState**

**Purpose** Set the Graffiti-shift state indicator.

**Declared In** `GraffitiShift.h`

**Prototype** `void GsiSetShiftState (const UInt16 lockFlags,  
const UInt16 tempShift)`

**Parameters** `lockFlags` `glfCapsLock` or `glfNumLock`.  
`tempShift` The current temporary shift.

**Result** Returns nothing.

**Comments** This function affects only the state of the UI element, not the underlying Graffiti engine.

**See Also** [`GrfSetState`](#)

# Insertion Point

---

This chapter provides reference material for the insertion point API, declared in the header file `InsPoint.h`.

For more information on the insertion point, see the section “[Insertion Point](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Insertion Point Functions

### InsPtEnable

|                    |                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Enable or disable the insertion point. When the insertion point is disabled, it’s invisible; when it’s enabled, it blinks.                                                                         |
| <b>Declared In</b> | <code>InsPoint.h</code>                                                                                                                                                                            |
| <b>Prototype</b>   | <code>void InsPtEnable (Boolean enableIt)</code>                                                                                                                                                   |
| <b>Parameters</b>  | <code>enableIt</code> <code>true = enable; false = disable</code>                                                                                                                                  |
| <b>Result</b>      | Returns nothing.                                                                                                                                                                                   |
| <b>Comments</b>    | This function is called by the Form functions when a text field loses or gains the focus, and by the Windows function when a region of the display is copied ( <a href="#">WinCopyRectangle</a> ). |
| <b>See Also</b>    | <a href="#">InsPtEnabled</a>                                                                                                                                                                       |

## Insertion Point

### *Insertion Point Functions*

---

#### **InsPtEnabled**

- Purpose** Return `true` if the insertion point is enabled or `false` if the insertion point is disabled.
- Declared In** `InsPoint.h`
- Prototype** `Boolean InsPtEnabled (void)`
- Parameters** None.
- Result** Returns `true` if the insertion point is enabled (blinking); returns `false` if the insertion point is disabled (invisible).
- See Also** [InsPtEnable](#)

#### **InsPtGetHeight**

- Purpose** Return the height of the insertion point.
- Declared In** `InsPoint.h`
- Prototype** `Int16 InsPtGetHeight (void)`
- Parameters** None.
- Result** Returns the height of the insertion point, in pixels.

## InsPtGetLocation

- Purpose** Return the screen-relative position of the insertion point.
- Declared In** `InsPoint.h`
- Prototype** `void InsPtGetLocation (Int16 *x, Int16 *y)`
- Parameters** `x, y` Pointer to top-left position of insertion point's x and y coordinate.
- Result** Returns nothing. Stores the location in `x` and `y`.
- Comments** This function is called by the Field functions. An application would not normally call this function.

## InsPtSetHeight

- Purpose** Set the height of the insertion point.
- Declared In** `InsPoint.h`
- Prototype** `void InsPtSetHeight (const Int16 height)`
- Parameters** `height` Height of the insertion point in pixels.
- Result** Returns nothing.
- Comments** Set the height of the insertion point to match the character height of the font used in the field that the insertion point is in. When the current font is changed, the insertion point height should be set to the line height of the new font.
- If the insertion point is visible when its height is changed, it's erased and redrawn with its new height.
- See Also** [InsPtGetHeight](#)

## Insertion Point

### *Insertion Point Functions*

---

## InsPtSetLocation

- Purpose** Set the screen-relative position of the insertion point.
- Declared In** `InsPoint.h`
- Prototype** `void InsPtSetLocation (const Int16 x,  
const Int16 y)`
- Parameters** `x, y` Number of pixels from the left side (top) of the display.
- Result** Returns nothing.
- Comments** The position passed to this function is the location of the top-left corner of the insertion point.  
This function should be called only by the Field functions.
- See Also** [InsPtGetLocation](#)

# Lists

---

This chapter provides information about list objects by discussing these topics:

- [List Data Structures](#)
- [List Resources](#)
- [List Functions](#)
- [Application-Defined Function](#)

The header file `List.h` declares the API that this chapter describes. For more information on lists, see the section “[Lists](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## List Data Structures

### ListAttrType

The `ListAttrType` bit field defines the visible characteristics of the list.

```
typedef struct {
    UInt16 usable           :1;
    UInt16 enabled         :1;
    UInt16 visible         :1;
    UInt16 poppedUp        :1;
    UInt16 hasScrollBar    :1;
    UInt16 search          :1;
    UInt16 reserved        :2;
} ListAttrType;
```

## Lists

---

#### Field Descriptions

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>usable</code>       | Set to make the list usable.<br><br>If not set, the list is not considered part of the current interface of the application, and does not appear on screen.                                                                                                                                                                                                                                                                                                        |
| <code>enabled</code>      | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>visible</code>      | Set when the list object is drawn, and cleared when the list object is erased.<br><br>This attribute is set and cleared internally.                                                                                                                                                                                                                                                                                                                                |
| <code>poppedUp</code>     | Set to indicate that the choices are displayed in a popup window.<br><br>This attribute is set and cleared internally.                                                                                                                                                                                                                                                                                                                                             |
| <code>hasScrollBar</code> | Set to indicate that the list has a scroll bar.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <code>search</code>       | Set to enable incremental search. If incremental search is enabled, when the list is displayed the user can navigate the list by entering up to five characters. The list will scroll to present the first list item that matches the entered characters. This feature only works for popup lists, and only works if the list is sorted and the list items are available to the List Manager (that is, you don't pass NULL to <a href="#">LstSetListChoices</a> ). |
| <code>reserved</code>     | Reserved for system use.                                                                                                                                                                                                                                                                                                                                                                                                                                           |

#### ListType

The `ListType` structure is defined below.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `ListType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

---

```

typedef struct {
    UInt16          id;
    RectangleType   bounds;
    ListAttrType    attr;
    Char            **itemsText;
    Int16           numItems;
    Int16           currentItem;
    Int16           topItem;
    FontID          font;
    UInt8           reserved;
    WinHandle       popupWin;
    ListDrawDataFuncPtr drawItemCallback;
} ListType;

```

### Field Descriptions

|        |                                                                                                                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id     | The ID value, specified by the application developer. This ID value is part of the event data of <a href="#">lstEnterEvent</a> and <a href="#">lstSelectEvent</a> .                                                                                                                                                     |
| bounds | <p>The bounds of the list, relative to the window. For example, to access the bounds of an object in a form whose ID is kObjectID:</p> <pre> {     RectangleType rect;     FormPtr formP =     FrmGetActiveForm();      FrmGetObjectBounds(formP,     FrmGetObjectIndex(formP,     kObjectID),     &amp;rect); } </pre> |
| attr   | The list attributes. See <a href="#">ListAttrType</a> .                                                                                                                                                                                                                                                                 |

## Lists

### List Data Structures

---

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| itemsText   | <p>A pointer to an array of pointers to the text of the choices. Access with <a href="#">LstGetSelectionText</a>.</p> <p>For example, to access the string specified by itemNum in the list whose ID is kChoiceList use the following:</p> <pre>{ Char *string; Int16 itemNum; ... string = LstGetSelectionText (GetObjectPtr ( kChoicesList), itemNum); }</pre> <p>where GetObjectPtr is the following:</p> <pre>static void *GetObjectPtr (UInt16 rsrcID) { FormPtr formP;  formP = FrmGetActiveForm(); return FrmGetObjectPtr (formP, FrmGetObjectIndex (formP, rsrcID)); }</pre> <p>If you use a callback routine to draw the list items, note that the itemsText pointer you supply to <a href="#">LstSetListChoices</a> is passed to your callback routine. See the comments under <a href="#">ListDrawDataFuncType</a> for tips on using itemsText with a callback routine.</p> |
| numItems    | <p>The number of choices in the list. Access with <a href="#">LstGetNumberOfItems</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| currentItem | <p>The currently-selected list choice (0 = first choice). Access with <a href="#">LstGetSelection</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| topItem     | <p>The first choice displayed in the list. Set this field with <a href="#">LstSetTopItem</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

|                  |                                                                                                                                                                                                              |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| font             | The ID of the font used to draw all list text strings.                                                                                                                                                       |
| reserved         | Reserved for future use.                                                                                                                                                                                     |
| popupWin         | The handle of the window created when a list is displayed by calling <a href="#">LstPopupList</a> .                                                                                                          |
| drawItemCallback | Function used to draw an item in the list. If NULL, the default drawing routine is used instead. Set this field with <a href="#">LstSetDrawFunction</a> . See <a href="#">Application-Defined Function</a> . |

## List Resources

The [List Resource](#) (tLST), and [Popup Trigger Resource](#) (tPUT) are used together to represent an active list.

## List Functions

### LstDrawList

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sets the visible attribute of the list object to true, and draws the list object if it is usable.                                                                                                       |
| <b>Declared In</b> | List.h                                                                                                                                                                                                  |
| <b>Prototype</b>   | void LstDrawList (ListType *listP)                                                                                                                                                                      |
| <b>Parameters</b>  | -> listP            Pointer to a list object ( <a href="#">ListType</a> ).                                                                                                                              |
| <b>Result</b>      | Returns nothing.                                                                                                                                                                                        |
| <b>Comments</b>    | If there are more choices than can be displayed, this function ensures that the current selection is visible. The current selection is highlighted. Note that this function does not ensure the current |

## Lists

### List Functions

---

selection is visible; if you need to do this, call the [LstMakeItemVisible](#) function.

If the list is disabled, it's drawn grayed-out (strongly discouraged). If it's empty, nothing is drawn. If it's not usable, nothing is drawn.

**See Also** [FrmGetObjectPtr](#), [LstPopupList](#), [LstEraseList](#)

## LstEraseList

**Purpose** Erase a list object.

**Declared In** `List.h`

**Prototype** `void LstEraseList (ListType *listP)`

**Parameters** `-> listP` Pointer to a list object ([ListType](#)).

**Result** Returns nothing.

**Comments** The `visible` attribute is set to `false` by this function.

**See Also** [FrmGetObjectPtr](#), [LstDrawList](#)

## LstGetNumberOfItems

**Purpose** Return the number of items in a list.

**Declared In** `List.h`

**Prototype** `Int16 LstGetNumberOfItems (const ListType *listP)`

**Parameters** `-> listP` Pointer to a list object ([ListType](#)).

**Result** Returns the number of items in a list.

**See Also** [FrmGetObjectPtr](#), [LstSetListChoices](#)

## LstGetSelection

- Purpose** Return the currently selected choice in the list.
- Declared In** `List.h`
- Prototype** `Int16 LstGetSelection (const ListType *listP)`
- Parameters** `-> listP` Pointer to a list object.
- Result** Returns the item number of the current list choice. The list choices are numbered sequentially, starting with 0; Returns `noListSelection` if none of the items are selected.
- See Also** [FrmGetObjectPtr](#), [LstSetListChoices](#), [LstSetSelection](#), [LstGetSelectionText](#)

## LstGetSelectionText

- Purpose** Return a pointer to the text of the specified item in the list, or `NULL` if no such item exists.
- Declared In** `List.h`
- Prototype** `Char *LstGetSelectionText (const ListType *listP, Int16 itemNum)`
- Parameters** `-> listP` Pointer to a list object.  
`-> itemNum` Item to select (0 = first item in list).
- Result** Returns a pointer to the text of the current selection, or `NULL` if out of bounds.
- Comments** This is a pointer within [ListType](#), not a copy. This function is only usable if you supplied an array of strings and a count to

## Lists

### List Functions

---

[LstSetListChoices](#); if your application uses a callback function that dynamically generates the list text, this function returns NULL.

**See Also** [FrmGetObjectPtr](#)

## LstGetTopItem

**Purpose** Returns the topmost visible item.

**Declared In** `List.h`

**Prototype** `Int16 LstGetTopItem (const ListType *listP)`

**Parameters** `-> listP` Pointer to a list object.

**Result** Returns the item number of the top item visible.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [LstGetSelection](#), [LstSetTopItem](#)

## LstGetVisibleItems

**Purpose** Return the number of visible items.

**Declared In** `List.h`

**Prototype** `Int16 LstGetVisibleItems (const ListType *listP)`

**Parameters** `-> listP` Pointer to a list object.

**Result** The number of items visible.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## LstHandleEvent

- Purpose** Handle event in the specified list; the list object must have its `usable` and `visible` attribute set to `true`. This routine handles two type of events, [penDownEvent](#) and [lstEnterEvent](#); see Comments.
- Declared In** `List.h`
- Prototype** `Boolean LstHandleEvent (ListType *listP, const EventType *eventP)`
- Parameters**
- > `listP` Pointer to a list object ([ListType](#)).
  - > `eventP` Pointer to an `EventType` structure.
- Result** Return `true` if the event was handled. The following cases will result in a return value of `true`:
- A `penDownEvent` within the bounds of the list
  - A `lstEnterEvent` with a list ID value that matches the list ID in the list data structure
- Comments** When this routine receives a `penDownEvent`, it checks if the pen position is within the bounds of the list object. If it is, this routine tracks the pen until the pen comes up. If the pen comes up within the bounds of the list, a `lstEnterEvent` is added to the event queue, and the routine is exited.
- When this routine receives a `lstEnterEvent`, it checks that the list ID in the event record matches the ID of the specified list. If there is a match, this routine creates and displays a popup window containing the list's choices and the routine is exited.
- If a `penDownEvent` is received while the list's popup window is displayed and the pen position is outside the bounds of the popup window, the window is dismissed. If the pen position is within the bounds of the window, this routine tracks the pen until it comes up. If the pen comes up outside the list object, a `lstEnterEvent` is added to the event queue.

## Lists

### List Functions

---

#### LstMakeItemVisible

- Purpose** Make an item visible, preferably at the top. If the item is already visible, make no changes.
- Declared In** `List.h`
- Prototype** `void LstMakeItemVisible (ListType *listP,  
Int16 itemNum)`
- Parameters**
- > `listP` Pointer to a list object ([ListType](#)).
  - > `itemNum` Item to select (0 = first item in list).
- Result** Returns nothing.
- Comments** Does *not* visually update the list. You must call [LstDrawList](#) to update it.
- See Also** [FrmGetObjectPtr](#), [LstSetSelection](#), [LstSetTopItem](#), [LstDrawList](#)

## LstNewList

|                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |

| <code>&lt;--&gt; formPP</code>  | Pointer to the pointer to the form in which the new list is installed. This value is not a handle; that is, the old <code>formPP</code> value is not necessarily valid after this function returns. In subsequent calls, always use the new <code>formPP</code> value returned by this function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |
| <code>-&gt; id</code>           | Symbolic ID of the list, specified by the developer. By convention, this ID should match the resource ID (not mandatory).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |
| <code>-&gt; x</code>            | Horizontal coordinate of the upper-left corner of the list's boundaries, relative to the window in which it appears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |
| <code>-&gt; y</code>            | Vertical coordinate of the upper-left corner of the list's boundaries, relative to the window in which it appears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |

| <code>-&gt; height</code>       | Height of the list, expressed in pixels. Valid values are 1 – 160.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |
| <code>-&gt; visibleItems</code> | Number of list items that can be viewed together.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                |                                                                                                                                                                                                                                                                                                  |                       |                                                                                                                           |                      |                                                                                                                      |                      |                                                                                                                    |                          |                                                                   |                           |                                                                    |                                 |                                                   |

## Lists

### List Functions

---

-> triggerId      Symbolic ID of the popup trigger associated with the new list (this ID is specified by the developer). A nonzero value for triggerID causes this function to create both the list and its associated popup trigger. If the list isn't a popup list, pass 0 for triggerId.

**Result**      Returns 0 if no error.

**Compatibility**      Implemented only if [3.0 New Feature Set](#) is present.

**See Also**      [LstDrawList](#), [FrmRemoveObject](#)

## LstPopupList

**Purpose**      Display a modal window that contains the items in the list.

**Declared In**      List.h

**Prototype**      Int16 LstPopupList (ListType \*listP)

**Parameters**      -> listP      Pointer to a list object.

**Result**      Returns the list item selected, or -1 if no item was selected.

**Comments**      Saves the previously active window. Creates and deletes the new popup window.

**See Also**      [FrmGetObjectPtr](#)

## **LstScrollList**

- Purpose** Scroll the list up or down a number of times.
- Declared In** `List.h`
- Prototype** `Boolean LstScrollList (ListType *listP,  
WinDirectionType direction, Int16 itemCount)`
- Parameters**
- > `listP`            Pointer to a list object.
  - > `direction`        Direction to scroll.
  - > `itemCount`        Items to scroll in direction.
- Result** Returns `true` when the list is actually scrolled, `false` otherwise.  
May return `false` if a scroll past the end of the list is requested.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## **LstSetDrawFunction**

- Purpose** Set a callback function to draw each item instead of drawing the item's text string.
- Declared In** `List.h`
- Prototype** `void LstSetDrawFunction (ListType *listP,  
ListDrawDataFuncPtr func)`
- Parameters**
- > `listP`            Pointer to a list object.
  - > `func`              Pointer to a function that draws items.
- Result** Returns nothing.

## Lists

### List Functions

---

**Comments** This function also adjusts `topItem` to prevent a shrunken list from being scrolled down too far. Use this function for custom draw functionality.

**See Also** [FrmGetObjectPtr](#), [LstSetListChoices](#),  
[ListDrawDataFuncType](#)

## LstSetHeight

**Purpose** Set the number of items visible in a list.

**Declared In** `List.h`

**Prototype** `void LstSetHeight (ListType *listP,  
Int16 visibleItems)`

**Parameters** `-> listP` Pointer to a list object.  
`-> visibleItems` Number of choices visible at once.

**Result** Returns nothing.

**Comments** This function doesn't redraw the list if it's already visible.

**See Also** [FrmGetObjectPtr](#)

## LstSetListChoices

**Purpose** Set the items of a list to the array of text string pointers passed to this function. This function erases the old list items.

**Declared In** `List.h`

**Prototype** `void LstSetListChoices (ListType *listP,  
Char **itemsText, Int16 numItems)`

**Parameters** `-> listP` Pointer to a list object.

- 
- > `itemsText`      Pointer to an array of text strings. See [SysFormPointerArrayToStrings](#) for one way to create this array of strings.
  - > `numItems`        Number of choices in the list.

**Result**      Returns nothing.

**Comments**    You need to call the `LstDrawList` function to update the list if it is displayed when you call this function.

---

**NOTE:** This function does not copy the strings in the `itemsText` array, which means that you need to ensure that the array is not moved or deallocated until after you are done with the list.

---

If you use a callback routine to draw the items in your list, the `itemsText` pointer is simply passed to that callback routine and is not otherwise used by the List Manager code. See the comments under [ListDrawDataFuncType](#) for tips on using the `itemsText` parameter with a callback routine.

## LstSetPosition

**Purpose**        Set the position of a list.

**Declared In**   `List.h`

**Prototype**    `void LstSetPosition (ListType *listP, Coord x, Coord y)`

**Parameters**    -> `listP`            Pointer to a list object  
                   -> `x`                    Left bound.

## Lists

### List Functions

---

-> y                      Top bound.

**Result**      Returns nothing.

**Comments**      The list is not redrawn. Don't call this function when the list is visible.

**See Also**      [FrmGetObjectPtr](#)

## LstSetSelection

**Purpose**      Set the selection for a list.

**Declared In**      List.h

**Prototype**      void LstSetSelection (ListType \*listP,  
                         Int16 itemNum)

**Parameters**      -> listP              Pointer to a list object.  
                         -> itemNum            Item to select (0 = first item in list,  
                                                                         noListSelection = none).

**Result**      Returns nothing.

**Comments**      The old selection, if any, is unselected. If the list is visible, the selected item is visually updated. The list is scrolled to the selection, if necessary, as long as the list object is both visible and usable.

## LstSetTopItem

|                    |                                                                                                                                                                                                  |          |                           |            |                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|---------------------------|------------|----------------------------------------------------------------------------|
| <b>Purpose</b>     | Set the item visible. The item cannot become the top item if it's on the last page.                                                                                                              |          |                           |            |                                                                            |
| <b>Declared In</b> | List.h                                                                                                                                                                                           |          |                           |            |                                                                            |
| <b>Prototype</b>   | <pre>void LstSetTopItem (ListType *listP,<br/>Int16 itemNum)</pre>                                                                                                                               |          |                           |            |                                                                            |
| <b>Parameters</b>  | <table><tr><td>-&gt; listP</td><td>Pointer to a list object.</td></tr><tr><td>-&gt; itemNum</td><td>Item to select (0 = first item in list). This must be a valid item number.</td></tr></table> | -> listP | Pointer to a list object. | -> itemNum | Item to select (0 = first item in list). This must be a valid item number. |
| -> listP           | Pointer to a list object.                                                                                                                                                                        |          |                           |            |                                                                            |
| -> itemNum         | Item to select (0 = first item in list). This must be a valid item number.                                                                                                                       |          |                           |            |                                                                            |
| <b>Result</b>      | Returns nothing.                                                                                                                                                                                 |          |                           |            |                                                                            |
| <b>Comments</b>    | Does <i>not</i> update the display.                                                                                                                                                              |          |                           |            |                                                                            |

---

**NOTE:** The value you specify for itemNum must be in the range 0 to max-number-of-items.

---

**See Also** [FrmGetObjectPtr](#), [LstSetSelection](#), [LstGetTopItem](#), [LstMakeItemVisible](#), [LstDrawList](#), [LstEraseList](#)

## Application-Defined Function

If you need to perform special drawing for items in the list, call [LstSetDrawFunction](#) to set the list drawing callback function. The [ListDrawDataFuncType](#) section documents the prototype for the callback function you provide for drawing list items.

### ListDrawDataFuncType

**Purpose** Callback function that you provide for drawing items in a list. This function is called whenever the Palm OS needs to draw an element

## Lists

### *Application-Defined Function*

---

in the list. Your callback function declaration must match the prototype shown here.

**Declared In** `List.h`

**Prototype** `void ListDrawDataFuncType(Int16 itemNum, RectangleType *bounds, Char **itemsText)`

**Parameters**

|                           |                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>itemNum</code>   | The number of the item to draw.                                                                                                                         |
| -> <code>bounds</code>    | The bounds of the list, relative to the window.                                                                                                         |
| -> <code>itemsText</code> | A pointer to an array of pointers to the text of the list items. This is the pointer that you supplied when calling <a href="#">LstSetListChoices</a> . |

**Result** Returns nothing.

**Comments** You can call [LstSetDrawFunction](#) to register your callback function for the list, which means that your function will be called to draw the list items, rather than using the built-in draw functionality, which displays each item's text string.

Your callback function is called whenever an item in the list needs to be drawn. When it is called, the value of the `itemNum` parameter specifies which item the function is to draw. The `itemsText` parameter, which is what was supplied to [LstSetListChoices](#), doesn't actually need to point to a list of strings: you can pass `NULL`, or you can pass a pointer to anything that will be useful to your drawing function. Note, however, that if you pass anything other than a pointer to a list of strings when you call [LstSetListChoices](#), you must ensure that [LstGetSelectionText](#) is never called since it assumes that this pointer indicates an array of text items. In particular, if your list is associated with a pop-up trigger you must handle the `popSelectEvent` yourself before [FrmHandleEvent](#) gets a chance at it since [FrmHandleEvent](#) calls [LstGetSelectionText](#).

---

**WARNING!** If the list is a popup list, the form that owns the list is not active while the list is in a window. This means that you cannot call the [FrmGetActiveForm](#) function. Instead, use `itemsText` pointer to access any information that you need for drawing. If you must access the form, use the [FrmGetFormPtr](#) function.

---

Note that the list object manages which colors are used to draw the items and how to draw selected versus unselected items. In almost all circumstances, your drawing function does not have to be concerned with these details.

However, if you do need to determine if the item is selected, you can rely on the fact that the system has set the pen color to one of two colors prior to calling your draw function:

- If the item is selected, the foreground color is `UIObjectSelectedForeground`.
- If the item is not selected, the foreground color is `UIObjectForeground`.

You can determine the foreground color that is in effect for the list item by calling the [WinSetForeColor](#) function, which returns the previous value of the foreground color. Remember to call `WinSetForeColor` again to reset the foreground color to what it was. For example:

```
itemColor = WinSetForeColor(myColor)
WinSetForeColor(itemColor)
selectColor = UIColorGetTableEntryIndex(
    UIObjectSelectedForeground)
if itemColor == selectColor
...

```

**See Also** [LstSetDrawFunction](#), [UIColorGetTableEntryIndex](#), [WinSetForeColor](#)

*Application-Defined Function*

---

# Menus

---

This chapter describes the menu API as declared in the header file `Menu.h`. It discusses the following topics:

- [Menu Data Structures](#)
- [Menu Constants](#)
- [Menu Resources](#)
- [Menu Functions](#)

For more information on menus, see the section “[Menus](#)” on page 105 in the *Palm OS Programmer’s Companion*, vol. I.

## Menu Data Structures

### MenuBarAttrType

The `MenuBarAttrType` bit field defines some characteristics of the menu bar.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `MenuBarAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 visible : 1;
    UInt16 commandPending : 1;
    UInt16 insPtEnabled : 1;
    UInt16 needsRecalc : 1;
} MenuBarAttrType;
```

## Menus

### Menu Data Structures

---

Your code should treat the `MenuBarAttrType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

#### Field Descriptions

|                             |                                                                                                                                                                                                                                                                               |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>visible</code>        | If set, the menu bar is drawn and visible on the screen. This attribute is set as part of <a href="#">MenuDrawMenu</a> , which is called when the menu is drawn.                                                                                                              |
| <code>commandPending</code> | If set, a menu command shortcut is in progress. This bit is set during <a href="#">MenuHandleEvent</a> if the menu shortcut keystroke is received. If the next key is received before the timeout value is reached, the key is examined to see if it is a valid menu command. |
| <code>insPtEnabled</code>   | Stores the state of the insertion point at the time the menu was drawn so that it can be restored when the menu is erased.                                                                                                                                                    |
| <code>needsRecalc</code>    | If set, recalculate menu dimensions.                                                                                                                                                                                                                                          |

**Compatibility** The `needsRecalc` constant is present only if [3.5 New Feature Set](#) is present.

#### MenuCmdBarButtonType

The `MenuCmdBarButtonType` structure defines a button to be displayed on the command toolbar. The `buttonsData` field of the [MenuCmdBarType](#) structure contains an array of structures of this type.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `MenuCmdBarButtonType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16    bitmapId;
    Char      name [menuCmdBarMaxTextLength] ;
    MenuCmdBarResultType resultType;
    UInt8     reserved;
    UInt32    result;
} MenuCmdBarButtonType;
```

Your code should treat the `MenuCmdBarButtonType` structure as opaque. Do not attempt to change structure member values directly. Instead, use [MenuCmdBarAddButton](#) to add a button to the display. For the most part, the parameters to `MenuCmdBarAddButton` are the same as the fields in the `MenuCmdBarButtonType`, so there should be no need to alter these fields directly.

[MenuCmdBarGetButtonData](#) can be called to access information about command bar buttons.

### Field Descriptions

|                         |                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>bitmapId</code>   | Resource ID of the bitmap to display on the button. This bitmap should be 13 pixels high by 16 pixels wide.           |
| <code>name</code>       | Text to display in the status message when the user taps the button.                                                  |
| <code>resultType</code> | Specifies what type of data is contained in the <code>result</code> field. See <a href="#">MenuCmdBarResultType</a> . |

## Menus

### Menu Data Structures

---

|          |                                                                                                                                                                                                                                                                                                                            |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| reserved | Reserved for future use.                                                                                                                                                                                                                                                                                                   |
| result   | Specifies the data to send when the user clicks the button. The data is interpreted as specified by the <code>resultType</code> field. The result can be a shortcut character to enqueue in a <a href="#">keyDownEvent</a> , a menu item ID to enqueue in a <a href="#">menuEvent</a> , or a notification to be broadcast. |

**Compatibility** This structure is defined only if [3.5 New Feature Set](#) is present.

## MenuCmdBarResultType

The `MenuCmdBarResultType` enum specifies how the `result` field in the [MenuCmdBarButtonType](#) structure should be interpreted.

```
typedef enum {
    menuCmdBarResultNone,
    menuCmdBarResultChar,
    menuCmdBarResultMenuItem,
    menuCmdBarResultNotify
} MenuCmdBarResultType;
```

### Value Descriptions

|                                       |                                                                                                        |
|---------------------------------------|--------------------------------------------------------------------------------------------------------|
| <code>menuCmdBarResultNone</code>     | Send nothing.                                                                                          |
| <code>menuCmdBarResultChar</code>     | The result is a character to send in a <a href="#">keyDownEvent</a> .                                  |
| <code>menuCmdBarResultMenuItem</code> | The result is the ID of the menu item to send in a <a href="#">menuEvent</a> .                         |
| <code>menuCmdBarResultNotify</code>   | The result is a notification constant to be broadcast using <a href="#">SysNotifyBroadcastDeferred</a> |

**Compatibility** This enum is defined only if [3.5 New Feature Set](#) is present.

## MenuCmdBarType

The MenuCmdBarType structure defines the command toolbar. This command toolbar is allocated and displayed when the user draws the shortcut stroke in the Graffiti® area. It is deallocated when [MenuEraseStatus](#) is called, which occurs most frequently when the timeout value has elapsed.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the MenuCmdBarType structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct MenuCmdBarType {
    WinHandle    bitsBehind;
    Int32        timeoutTick;
    Coord        top;
    Int16        numButtons;
    Boolean       insPtWasEnabled;
    Boolean       gsiWasEnabled;
    Boolean       feedbackMode;
    MenuCmdBarButtonType *buttonsData;
} MenuCmdBarType;
```

Your code should treat the MenuCmdBarType structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|             |                                                                                                                                                                                                                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bitsBehind  | Handle for the window that contains the region obscured by the command toolbar.                                                                                                                                                                                                                |
| timeoutTick | Timeout value given in system ticks. If the user hasn't specified a command after this many ticks, the command toolbar is erased from the screen and deallocated from memory. This value also specifies how long the status message is displayed after the user successfully enters a command. |

## Menus

### Menu Data Structures

---

|                              |                                                                                                                                                                                                                                            |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>top</code>             | The top bound of the command toolbar given in display-relative coordinates. The command toolbar is as wide as the screen and displays at the bottom of the screen.                                                                         |
| <code>numButtons</code>      | Number of buttons displayed on the command toolbar.                                                                                                                                                                                        |
| <code>insPtWasEnabled</code> | If <code>true</code> , the insertion point was enabled before the command toolbar was displayed and should be re-enabled when the command toolbar is erased. If <code>false</code> , the insertion point was disabled.                     |
| <code>gsiWasEnabled</code>   | If <code>true</code> , the Graffiti shift indicator was enabled before the command toolbar was displayed and should be re-enabled when the command toolbar is erased. If <code>false</code> , the Graffiti shift indicator was disabled.   |
| <code>feedbackMode</code>    | If <code>true</code> , the command toolbar is currently displaying a status message. The status message is displayed to tell the user what command is being performed. If <code>false</code> , the command toolbar is awaiting input.      |
| <code>buttonsData</code>     | The list of buttons to display on the command toolbar. See <a href="#">MenuCmdBarButtonType</a> . Buttons are stored in this list sequentially with the rightmost button at index 0. Access with <a href="#">MenuCmdBarGetButtonData</a> . |

**Compatibility** This structure is defined only if [3.5 New Feature Set](#) is present.

## MenuBarPtr

The `MenuBarPtr` type defines a pointer to a [MenuBarType](#).

```
typedef MenuBarType *MenuBarPtr;
```

## MenuBarType

The MenuBarType structure defines the menu bar. There is one menu bar per form.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the MenuBarType structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    WinHandle      barWin;
    WinHandle      bitsBehind;
    WinHandle      savedActiveWin;
    WinHandle      bitsBehindStatus;
    MenuBarAttrType attr;
    Int16          curMenu;
    Int16          curItem;
    Int32          commandTick;
    Int16          numMenus;
    MenuPullDownPtr menus;
} MenuBarType;
```

Your code should treat the MenuBarType structure as opaque. Do not attempt to change structure member values directly.

### Field Descriptions

|                |                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------|
| barWin         | Handle for the window that contains the menu bar.                                                     |
| bitsBehind     | Handle for the window that contains the region obscured by the menu bar.                              |
| savedActiveWin | Handle where the currently active window is saved so that it can be restored when the menu is erased. |

## Menus

### Menu Data Structures

---

|                               |                                                                                                                                                                                                                                                    |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bitsBehindStatus</code> | Handle where the bits behind the status message are saved so that when the message display terminates, the bits can be restored.<br><br>The status message is displayed when the user activates the menu through the use of the command keystroke. |
| <code>attr</code>             | Menu bar attributes. See <a href="#">MenuBarAttrType</a> .                                                                                                                                                                                         |
| <code>curMenu</code>          | Menu number for the currently visible menu. Menus are numbered sequentially starting with 0. The value is preserved when the menu bar is dismissed. A value of <code>noMenuSelection</code> indicates that there is no current pull-down menu.     |
| <code>curItem</code>          | Item number of the currently highlighted menu item. The items in each menu are numbered sequentially, starting with zero.<br><br>A value of <code>noMenuItemSelection</code> indicates that there is no current item selected.                     |
| <code>commandTick</code>      | Tick count at which the status message should be erased.                                                                                                                                                                                           |
| <code>numMenus</code>         | Number of pull-down menus on the menu bar.                                                                                                                                                                                                         |
| <code>menus</code>            | Array of <a href="#">MenuPullDownType</a> structures.                                                                                                                                                                                              |

**Compatibility** If [3.5 New Feature Set](#) is present, the `bitsBehindStatus` and `commandTick` fields are defined but are not used. Instead, the `bitsBehind` and `timeoutTick` fields in [MenuCmdBarType](#) define the save-behind window and the timeout value for the command toolbar.

## MenuItemType

The MenuItemType structure defines a specific item within a menu. The items array in the [MenuPullDownType](#) structure contains one MenuItemType structure for each menu item in the pull-down menu.

If [3.5 New Feature Set](#) is present, you can add a menu item to a pull-down menu programmatically using [MenuAddItem](#).

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the MenuItemType structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

## Menus

### Menu Data Structures

---

```
typedef struct {
    UInt16    id;
    Char      command;
    UInt8     hidden: 1;
    UInt8     reserved: 7;
    Char      *itemStr;
} MenuItemType;
```

#### Field Descriptions

|          |                                                                                                                                                                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id       | ID value you specified when you created the menu item. This ID value is included as part of the event data of a <a href="#">menuItemEvent</a> .                                                                                                                                                                                           |
| command  | Shortcut key. If you provide shortcuts, make sure that each shortcut is unique among all commands available at that time.                                                                                                                                                                                                                 |
| hidden   | If true, the menu item is hidden. If false, it is displayed. You can set and clear this value using <a href="#">MenuItemHideItem</a> and <a href="#">MenuItemShowItem</a> .                                                                                                                                                               |
| reserved | Reserved for future use.                                                                                                                                                                                                                                                                                                                  |
| itemStr  | Pointer to the text to display for this menu item, including the shortcut key. To include a shortcut key, begin the string with the item's text, then type a tab character, and then the item's shortcut key.<br><br>To create a separator bar, create a one-character string containing the <code>MenuItemSeparatorChar</code> constant. |

**Compatibility** The hidden and reserved fields are defined only if [3.5 New Feature Set](#) is present.

## MenuPullDownPtr

The `MenuPullDownPtr` type defines a pointer to a [MenuPullDownType](#).

```
typedef MenuPullDownType *MenuPullDownPtr;
```

## MenuPullDownType

The `MenuPullDownType` structure defines a specific menu accessed from the menu bar. The menus array in the [MenuBarType](#) structure contains one `MenuPullDownType` structure for each pull-down menu associated with the menu bar.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `MenuPullDownType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    WinHandle      menuWin;
    RectangleType  bounds;
    WinHandle      bitsBehind;
    RectangleType  titleBounds;
    Char           *title;
    UInt16         hidden : 1;
    UInt16         numItems : 15;
    MenuItemType  *items;
} MenuPullDownType;
```

### Field Descriptions

|                         |                                                                   |
|-------------------------|-------------------------------------------------------------------|
| <code>menuWin</code>    | Handle for the window that contains the menu.                     |
| <code>bounds</code>     | Position and size, in pixels, of the pull-down menu.              |
| <code>bitsBehind</code> | Handle of a window that contains the region obscured by the menu. |

## Menus

### Menu Constants

---

|                          |                                                                                                                       |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <code>title</code>       | The menu title (null-terminated string) displayed in the menu bar.                                                    |
| <code>titleBounds</code> | Position and size, in pixels, of the title in the menu bar.                                                           |
| <code>hidden</code>      | If <code>true</code> , the menu is hidden; if <code>false</code> , it is displayed. This field is not currently used. |
| <code>numItems</code>    | Number of items in the menu. Separators count as items.                                                               |
| <code>items</code>       | Array of <a href="#">MenuItemType</a> structures.                                                                     |

**Compatibility** The `hidden` field is defined only if [3.5 New Feature Set](#) is present.

## Menu Constants

---

| Constant                            | Value | Description                                                                                                                                                                                                    |
|-------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>noMenuSelection</code>        | -1    | The <code>curMenu</code> field of <a href="#">MenuBarType</a> is set to this when there is no currently selected menu.                                                                                         |
| <code>noMenuItemSelection</code>    | -1    | The <code>curItem</code> field of <a href="#">MenuBarType</a> is set to this when there is no currently selected menu item.                                                                                    |
| <code>separatorItemSelection</code> | -2    | The <code>curItem</code> field of <a href="#">MenuBarType</a> is set to this when a menu separator item is selected.                                                                                           |
| <code>MenuSeparatorChar</code>      | '-'   | Special character indicating that the menu item is a bar used to separate groups of related menu items. The first character of the <code>itemStr</code> string in <a href="#">MenuItemType</a> is set to this. |

---

## Menu Resources

The menu bar (MBAR) and pull-down menu (MENU) resources are used jointly to represent a menu object on screen. See “[Menus and Menu Bars](#)” in [Chapter 2, “Palm OS Resources.”](#)

## Menu Functions

### MenuItem

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                                                                               |       |                                        |        |                                                                                                                           |          |                                                                                                                                                                                                                                                                                                                              |

## Menus

### Menu Functions

---

`menuErrSameId` The menu already contains an item with the ID `id`.

`menuErrNotFound`  
The menu doesn't contain an item with the ID `positionId`.

May display a fatal error message if there is no current menu.

**Comments** This function creates a new [MenuItemType](#) structure and adds it to the [MenuBarType](#)'s item list.

You should call this function only in response to a [menuOpenEvent](#). This event is generated when the menu is first made active. In general, a form's menu becomes active the first time a [keyDownEvent](#) with a `vchrMenu` or `vchrCommand` is generated, and it remains active until a new form (including a modal form or alert panel) is displayed or until [FrmSetMenu](#) is called to change the form's menu. Palm OS® user interface guidelines discourage adding or hiding menu items at any time other than when the menu is first made active.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## MenuCmdBarAddButton

**Purpose** Defines a button to be displayed on the command toolbar.

**Declared In** `Menu.h`

**Prototype** `Err MenuCmdBarAddButton (UInt8 where, UInt16 bitmapId, MenuCmdBarResultType resultType, UInt32 result, Char *nameP)`

**Parameters** `-> where` Either `menuCmdBarOnLeft` to add the button to the left of the other buttons on the command toolbar, `menuCmdBarOnRight` to add it to the right of the other buttons, or a number indicating the exact position of the button. Button positions are numbered from right to left, and the rightmost position is number 1.

|                            |                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>bitmapId</code>   | Resource ID of the bitmap to display on the button. The bitmap's dimensions should be 13 pixels high by 16 pixels wide.                                                                                                                                                                                                                                             |
| -> <code>resultType</code> | The type of data contained in the <code>result</code> parameter. See <a href="#">MenuCmdBarResultType</a> .                                                                                                                                                                                                                                                         |
| -> <code>result</code>     | The data to send when the user taps this button. This can be a character, a menu item ID, or a notification constant.                                                                                                                                                                                                                                               |
| -> <code>nameP</code>      | Pointer to the text to display in the status message if the user taps the button. If <code>NULL</code> , the text is taken from the menu item that matches the ID or shortcut character contained in <code>result</code> , if a match is found.<br><br>If you supply a text buffer for this parameter, <code>MenuCmdBarAddButton</code> makes a copy of the buffer. |

**Result** Returns 0 upon success, or one of the following error codes:

`menuErrOutOfMemory`

There is not enough memory available to perform the operation.

`menuErrTooManyItems`

The command toolbar already has the maximum number of buttons allowed (currently 8).

**Comments** Call this function in response to a [menuCmdBarOpenEvent](#) or to the notification [sysNotifyMenuCmdBarOpenEvent](#). Both of these signal that the user has entered the command keystroke and the command toolbar is about to open. Your response should be to add buttons to the toolbar and to return `false`, indicating that you have not completely handled the event.

The `sysNotifyMenuCmdBarOpenEvent` notification is intended to be used only by shared libraries, system extensions, and other code resources that do not use an event loop. If you're writing an application, always respond to the event instead of the notification; an application should only add buttons to the toolbar if it is the

## Menus

### Menu Functions

---

current application. If you register for the notification, you receive it each time the command toolbar is displayed, whether your application is active or not.

Note that the command toolbar is allocated each time it is opened and is deallocated when it is erased from the screen.

There is a limited amount of space in which to display buttons on the command toolbar. You should limit the number of buttons to four or five. The maximum allowed by the system is eight, but you should leave space for the status message that appears after the user chooses an action. Buttons should be contextual; for example, the field code only displays a paste button if there is text on the clipboard. Bitmaps for the buttons should be 16 X 13 pixels.

If a field has focus when the command toolbar is opened, the field manager adds buttons for cut, copy, paste, and undo. If your application does not want this default behavior, set the `preventFieldButtons` field in the `menuCmdBarOpenEvent` structure to `true`. (Note that there is no way to prevent the field buttons from being drawn from within a notification handler.)

The following bitmaps for command toolbar buttons are defined in `UIResources.h`. The system and the built-in applications use these bitmaps to represent the commands listed in the table. Your application should also use them if it performs the same actions. If you use any of these buttons, add them in the order shown from right to left. (For example, `BarDeleteBitmap`, if used, should always be the rightmost button.)

---

| <b>Bitmap</b>                | <b>Command</b>                               |
|------------------------------|----------------------------------------------|
| <code>BarDeleteBitmap</code> | Delete record.                               |
| <code>BarPasteBitmap</code>  | Paste clipboard contents at insertion point. |
| <code>BarCopyBitmap</code>   | Copy selection.                              |
| <code>BarCutBitmap</code>    | Cut selection.                               |
| <code>BarUndoBitmap</code>   | Undo previous action.                        |
| <code>BarSecureBitmap</code> | Show Security dialog.                        |

---

| <b>Bitmap</b> | <b>Command</b>               |
|---------------|------------------------------|
| BarBeamBitmap | Beam current record.         |
| BarInfoBitmap | Show Info dialog (Launcher). |

It is best to add buttons on the left side. If you add buttons to the right, this function moves all existing buttons over one position to the left. You can also specify an exact position for the where parameter. The positions are numbered from right to left with the rightmost position being 1. If you specify an exact position, the function leaves space for the other buttons. For example, if you specify position 3 and there are no buttons displayed at positions 1 and 2, there will be blank spots to the right of your button.

The `result` and `resultType` parameters specify what the result should be if the user taps the button. `result` contains the actual data, and `resultType` contains a constant that specifies the type of data in `result`. Typically, the result is to enqueue a [menuEvent](#). In this case, `resultType` is `menuCmdBarResultMenuItem` and the `result` is the ID of the menu item that should included in the event.

You may also specify the shortcut character instead of the menu ID; however, doing so is inefficient. When `result` is a shortcut character, the [MenuHandleEvent](#) function enqueues a [keyDownEvent](#) with the character in `result`. During the next cycle of the event loop, `MenuHandleEvent` enqueues a `menuEvent` in response to the `keyDownEvent`. Thus, it is better to have your button enqueue the `menuEvent` directly.

If you call `MenuCmdBarAddButton` outside of an application, you might not know of any menu items in the active menu (unless your code has added one using [MenuAddItem](#)). In this case, specify a notification to be broadcast. The notification is broadcast at the top of the next event loop, and it must contain no custom data. (Applications may also use the notification result type.)

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

#### MenuCmdBarDisplay

|                      |                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Displays the command toolbar.                                                                                                                                                                                                                 |
| <b>Declared In</b>   | Menu.h                                                                                                                                                                                                                                        |
| <b>Prototype</b>     | <code>void MenuCmdBarDisplay (void)</code>                                                                                                                                                                                                    |
| <b>Parameters</b>    | None                                                                                                                                                                                                                                          |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                              |
| <b>Comments</b>      | This function displays the command toolbar when the user enters the command keystroke. You normally do not call this function in your own code. The form manager calls it at the end of its handling of <a href="#">menuCmdBarOpenEvent</a> . |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                           |
| <b>See Also</b>      | <a href="#">MenuCmdBarAddButton</a> , <a href="#">MenuCmdBarGetButtonData</a>                                                                                                                                                                 |

#### MenuCmdBarGetButtonData

|                    |                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Gets the data for a given command button.                                                                                                                        |
| <b>Declared In</b> | Menu.h                                                                                                                                                           |
| <b>Prototype</b>   | <code>Boolean MenuCmdBarGetButtonData<br/>(Int16 buttonIndex, UInt16 *bitmapIdP,<br/>MenuCmdBarResultType *resultTypeP,<br/>UInt32 *resultP, Char *nameP)</code> |
| <b>Parameters</b>  | -> buttonIndex    Index of the button for which you want to obtain information. Buttons are ordered from right to left, with the rightmost button at index 0.    |

|                                |                                                                                                                                                                                                                                                                |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- bitmapIdP</code>   | The resource ID of the bitmap displayed on the button. Pass <code>NULL</code> if you don't want to retrieve this value.                                                                                                                                        |
| <code>&lt;- resultTypeP</code> | The type of action this button takes. Pass <code>NULL</code> if you don't want to retrieve this value.                                                                                                                                                         |
| <code>&lt;- resultP</code>     | The result of tapping the button. Pass <code>NULL</code> if you don't want to retrieve this information.                                                                                                                                                       |
| <code>&lt;- nameP</code>       | The text displayed in the status message when this button is tapped. Pass <code>NULL</code> if you don't want to retrieve this information. If not <code>NULL</code> , <code>nameP</code> must point to a string of <code>menuCmdBarMaxTextLength</code> size. |

**Result** Returns `true` if the information was retrieved successfully, `false` if there is no command toolbar or if there is no button at `buttonIndex`.

**Comments** You can use this function to retrieve information about the buttons that are displayed on the command toolbar. If the command toolbar has not yet been initialized, this function returns `false`.

Note that the command toolbar is allocated when the user enters the command keystroke and deallocated when [MenuEraseStatus](#) is called. Thus, the only logical place to call `MenuCmdBarGetButtonData` is in response to a [menuCmdBarOpenEvent](#) or [sysNotifyMenuCmdBarOpenEvent](#) notification.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [MenuCmdBarDisplay](#), [MenuCmdBarAddButton](#)

## Menus

### Menu Functions

---

## MenuDispose

- Purpose** Releases any memory allocated to the menu and the command status and restore any saved bits to the screen.
- Declared In** `Menu.h`
- Prototype** `void MenuDispose (MenuBarType *menuP)`
- Parameters** `-> menuP` Pointer to the menu object to dispose. (See [MenuBarType](#).) If `NULL`, this function returns immediately.
- Result** Returns nothing.
- Comments** Most applications do not need to call this function directly. `MenuDispose` is called by the system when the form that contains the menu is no longer the active form, when the form that contains the menu is freed, and when [FrmSetMenu](#) is called to change the form's menu bar.
- See Also** [MenuInit](#), [MenuDrawMenu](#)

## MenuDrawMenu

- Purpose** Draws the current menu bar and the last pull-down that was visible.
- Declared In** `Menu.h`
- Prototype** `void MenuDrawMenu (MenuBarType *menuP)`
- Parameters** `-> menuP` Pointer to a [MenuBarType](#). Must not be `NULL`.
- Result** Returns nothing.
- Comments** Most applications do not need to call this function directly. [MenuHandleEvent](#) calls `MenuDrawMenu` when the user taps the

Menu silk-screen button (or taps the form's title on Palm OS 3.5 and higher).

The menu bar and the pull-down menu are drawn in front of all the application windows. The state of the insertion point, the bits that are obscured by the menu bar and the pull-down menu, and the currently active window are saved before the menu is drawn. These are all restored when the menu is erased.

A menu keeps track of the last pull-down menu displayed for as long as the menu is active. A menu loses its active status under these conditions:

- When [FrmSetMenu](#) is called to change the active menu on the form.
- When a new form, even a modal form or alert panel, becomes active.

Suppose a user selects your application's About item from the Options menu then clicks the OK button to return to the main form. When the About dialog is displayed, it becomes the active form, which causes the main form's menu state to be erased. This menu state is not restored when the main form becomes active again. The next time `MenuDrawMenu` is called (that is, the next time the user taps the Menu silk-screen button), the menu bar is displayed as it was before, and the first pull-down menu listed in the menu bar is displayed instead of the Options pull-down menu.

**See Also** [MenuInit](#), [MenuDispose](#)

### MenuEraseStatus

- Purpose** Erases the menu command status.
- Declared In** `Menu.h`
- Prototype** `void MenuEraseStatus (MenuBarType *menuP)`
- Parameters** `-> menuP` Pointer to a [MenuBarType](#), or NULL for the current menu.
- Result** Returns nothing.
- Comments** When the user selects a menu command using the command keystroke, the command toolbar or status message is displayed at the bottom of the screen. `MenuEraseStatus` erases the toolbar or status message.
- Under most circumstances, you do not need to call this function explicitly—just let the current menu command status remove itself automatically. Otherwise, you may cause text to be erased before the user has a chance to see it.
- You need to call `MenuEraseStatus` explicitly only if the command toolbar covers something that is going to be changed by the menu command the user has selected. For example, if the user selects a command that displays a new form, call `MenuEraseStatus` before executing the command. Also, if the command performs some drawing in the lower portion of the window, call `MenuEraseStatus` before performing the drawing function.
- Compatibility** The exact behavior when a menu shortcut character is entered depends on which version of the operating system is running. In versions prior to release 3.5, the system displays the string “Command:” in the lower-left portion of the screen when the user enters the Graffiti command keystroke.
- In Palm OS 3.5 and higher, entering the Graffiti command keystroke displays the command toolbar. This toolbar is the entire width of the screen and it displays buttons that the user can tap instead of entering another keystroke. If the user taps a button or enters a

character that matches a shortcut character for an item on the active menu, a status message is displayed in the toolbar while the command is executed. Calling `MenuEraseStatus` on Palm OS 3.5 and higher deallocates the command toolbar data structure as well as erasing the command toolbar from the screen.

Because the command toolbar takes up more of the display than the pre-Palm OS 3.5 status message, you may find you need to call `MenuEraseStatus` more frequently in Palm OS 3.5 than in earlier versions.

**See Also** [MenuInit](#)

## **MenuGetActiveMenu**

**Purpose** Returns a pointer to the currently active menu.

**Declared In** `Menu.h`

**Prototype** `MenuBarType *MenuGetActiveMenu (void)`

**Parameters** None.

**Result** Returns a pointer to the currently active menu, or `NULL` if there is none.

**Comments** An active menu is not necessarily visible on the screen. A menu might be active but not visible, for example, if a command shortcut has been entered. In general, a form's menu becomes active the first time a [keyDownEvent](#) with a `vchrMenu` or `vchrCommand` is generated, and it remains active until a new form (including a modal form or alert panel) is displayed or until [FrmSetMenu](#) is called to change the form's menu.

Applications that perform custom drawing to a window often check to see if the menu is visible to ensure that they don't draw on top of the menu. See "[Checking Menu Visibility](#)" on page 107 of the *Palm*

## Menus

### Menu Functions

---

*OS Programmer's Companion*, vol. I for instructions on how to verify a menu's visibility.

**See Also** [MenuHandleEvent](#), [MenuSetActiveMenu](#)

## MenuHandleEvent

**Purpose** Handles events in the current menu. This routine handles two types of events, [penDownEvent](#) and [keyDownEvent](#).

**Declared In** `Menu.h`

**Prototype** `Boolean MenuHandleEvent (MenuBarType *menuP, EventType *event, UInt16 *error)`

**Parameters**

|          |                                                                              |
|----------|------------------------------------------------------------------------------|
| -> menuP | Pointer to a MenuBarType data structure.                                     |
| -> event | Pointer to an EventType structure.                                           |
| -> error | Error (or 0 if no error). Currently this function always sets error to zero. |

**Result** Returns `true` if the event is handled; that is, if the event is a [penDownEvent](#) within the menu bar or the menu, or the event is a [keyDownEvent](#) that the menu supports. Returns `false` on any other event.

**Comments** When a [penDownEvent](#) is received in the menu bar, `MenuHandleEvent` tracks the pen until it comes up. If the pen comes up within the bounds of the menu bar, the selected title is inverted and the appropriate pull-down menu is drawn. Any previous pull-down menu is erased. If the pen comes up outside of the menu bar and pull-down menu, the menu is erased.

When a `penDownEvent` is received in a pull-down menu, `MenuHandleEvent` tracks the pen until it comes up. If the pen comes up within the bounds of the menu, a [menuEvent](#) containing the resource ID of the selected menu item is added to the event queue. If the pen comes up outside of the bounds of the menu and menu bar, the menu is erased.

If a [keyDownEvent](#) is received with a `vchrMenu`, the menu is drawn if it is not visible and erased if it is visible.

If a `keyDownEvent` is received with a `vchrCommand`, a command shortcut is in progress. Command shortcuts are handled differently depending on which version of Palm OS is running. On versions earlier than 3.5, the next `keyDownEvent` is checked to see if it is a valid menu shortcut. If so, a [menuEvent](#) is added to the event queue.

If a `keyDownEvent` is received with a `vchrCommand` on Palm OS 3.5 and higher, `MenuHandleEvent` enqueues a [menuCmdBarOpenEvent](#) if the command toolbar is not already open. The `menuCmdBarOpenEvent` provides a chance for applications to add their own buttons to the command toolbar. The next event might be either a `keyDownEvent` with a character that completes the shortcut or a `penDownEvent` on one of the buttons on the toolbar. The `keyDownEvent` is processed as with the earlier releases— if it is a valid menu shortcut, a [menuEvent](#) is added to the event queue. If the next event is a `penDownEvent`, the pen is tracked until it comes up. If the pen comes up within the bounds of a button, the appropriate action is taken. See the description of [MenuCmdBarAddButton](#) for more information.

In Palm OS version 3.5 or higher, if either the `vchrMenu` or the `vchrCommand` event causes a menu to be activated and initialized for the first time, a [menuOpenEvent](#) containing the reason the menu was initialized (`menuButtonCause` for a `vchrMenu` or `menuCommandCause` for a `vchrCommand`) is added to the event queue, and then the current event is added after it.

## Menus

### Menu Functions

---

## MenuHideItem

- Purpose** Makes the specified menu item hidden.
- Declared In** `Menu.h`
- Prototype** `Boolean MenuHideItem (UInt16 id)`
- Parameters** `-> id` ID of the menu item to hide.
- Result** Returns `true` if the `hidden` attribute of the specified item was successfully enabled, `false` otherwise.
- Comments** You should call this function only in response to a [menuOpenEvent](#). This event is generated when the menu is first made active. In general, a form's menu becomes active the first time a [keyDownEvent](#) with a `vchrMenu` or `vchrCommand` is generated, and it remains active until a new form (including a modal form or alert panel) is displayed or until [FrmSetMenu](#) is called to change the form's menu. Palm OS user interface guidelines discourage adding or hiding menu items at any time other than when the menu is first made active.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [MenuShowItem](#)

## MenuInit

- Purpose** Loads a menu resource from a resource file.
- Declared In** `Menu.h`
- Prototype** `MenuBarType *MenuInit (UInt16 resourceId)`
- Parameters** `-> resourceId` ID that identifies the menu resource.
- Result** Returns the pointer to a memory block allocated to hold the menu resource (a pointer to a [MenuBarType](#)).
- Comments** The menu is not usable until [MenuSetActiveMenu](#) is called. Typically, you do not need to call this function directly. A form stores the resource ID of the menu associated with it and initializes that menu as necessary. If you want to change the form's menu, call [FrmSetMenu](#), which handles disposing of the form's current menu, associating the new menu with the form, and initializing when needed.
- See Also** [MenuSetActiveMenu](#), [MenuDispose](#)

## MenuSetActiveMenu

- Purpose** Sets the current menu.
- Declared In** `Menu.h`
- Prototype** `MenuBarType *MenuSetActiveMenu (MenuBarType *menuP)`
- Parameters** `-> menuP` Pointer to the memory block that contains the new menu, or NULL for none.
- Result** Returns a pointer to the menu that was active before the new menu was set, or NULL if no menu was active.

## Menus

### Menu Functions

---

**Comments** This function sets the active menu but does not associate it with a form. It's recommended that you call [FrmSetMenu](#) instead of `MenuSetActiveMenu`. `FrmSetMenu` sets the active menu, frees the old menu, and associates the newly active menu with the form, which means the menu will be freed when the form is freed.

**See Also** [MenuGetActiveMenu](#)

## MenuSetActiveMenuRscID

**Purpose** Sets the current menu by resource ID.

**Declared In** `Menu.h`

**Prototype** `void MenuSetActiveMenuRscID (UInt16 resourceId)`

**Parameters** `-> resourceId` Resource ID of the menu to be made active.

**Result** Returns nothing.

**Comments** This function is similar to [MenuSetActiveMenu](#) except that you pass the menu's resource ID instead of a pointer to a menu structure. It is used as an optimization; with `MenuSetActiveMenu`, you must initialize the menu before making it active. Potentially, the application may exit before the menu is needed, making this memory allocation unnecessary. `MenuSetActiveMenuRscID` simply stores the resource ID. The next time a menu is requested, the menu is initialized from this resource.

It's recommended that you call [FrmSetMenu](#) instead of calling this function for the reasons given in `MenuSetActiveMenu`.

**Compatibility** Implemented only if "[2.0 New Feature Set](#)" is present.

## **MenuShowItem**

- Purpose** Makes the specified menu item visible.
- Declared In** `Menu.h`
- Prototype** `Boolean MenuShowItem (UInt16 id)`
- Parameters** `-> id` ID of the menu item to display.
- Result** Returns `true` if the `hidden` attribute of the specified item was successfully disabled, `false` otherwise.

## Menus

### Menu Functions

---

**Comments** You should call this function only in response to a [menuOpenEvent](#). This event is generated when the menu is first made active. In general, a form's menu becomes active the first time a [keyDownEvent](#) with a `vchrMenu` or `vchrCommand` is generated, and it remains active until a new form (including a modal form or alert panel) is displayed or until [FrmSetMenu](#) is called to change the form's menu. Palm OS user interface guidelines discourage adding or hiding menu items at any time other than when the menu is first made active.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

# Private Records

---

This chapter describes the private records API as declared in `PrivateRecords.h`. It discusses the following topics:

- [Private Record Data Structures](#)
- [Private Record Functions](#)

## Private Record Data Structures

### `privateRecordViewEnum`

The `privateRecordViewEnum` enumerated type provides the available choices for displaying private records.

```
typedef enum privateRecordViewEnum {  
    showPrivateRecords = 0x00,  
    maskPrivateRecords,  
    hidePrivateRecords  
} privateRecordViewEnum;
```

#### Value Descriptions

`showPrivateRecords` Display private records in the user interface.

`maskPrivateRecords` Show a shaded rectangle in place of a private record.

`hidePrivateRecords` Hide private records and provide no indication in the user interface that they exist.

# Private Record Functions

## SecSelectViewStatus

- Purpose** Display a form that allows the user to select whether to hide, show, or mask private records.
- Declared In** `PrivateRecords.h`
- Prototype** `privateRecordViewEnum SecSelectViewStatus (void)`
- Parameters** None
- Result** Returns a constant that indicates which option the user selected. See [privateRecordViewEnum](#).
- Comments** This function displays a dialog that allows users to change the preference `prefShowPrivateRecords`, which controls how private records are displayed.
- When the user taps the OK button in this dialog, [SecVerifyPW](#) is called to see if the user changed the preference setting and, if so, to prompt the user to enter the appropriate password.
- After calling this function, your code should check the return value or the value of `prefShowPrivateRecords` and mask, display, or hide the private records accordingly. See the description of [TblSetRowMasked](#) for a partial example.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## SecVerifyPW

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Display a password dialog, verify the password, and change the private records preference.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Declared In</b>   | <code>PrivateRecords.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Prototype</b>     | <code>Boolean SecVerifyPW<br/>(privateRecordViewEnum newSecLevel)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>    | <code>-&gt; newSecLevel</code> The security level (display, hide, or mask) selected on the private records dialog.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Result</b>        | Returns <code>true</code> if the <code>prefShowPrivateRecords</code> preference was successfully changed, <code>false</code> if not.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Comments</b>      | <p>This function checks <code>newSecLevel</code> against the current value for the preference. If the two values differ and <code>newSecLevel</code> indicates a decrease in security, a dialog is displayed prompting the user to enter a password. (Hidden is considered the most secure, followed by masked. Showing private records is considered the least secure.) If the password is entered successfully, the preference is changed.</p> <p>This function also displays an alert message if the security level has changed to either hidden or masked.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

# Progress Manager

---

This chapter provides reference material for the Progress Manager.

- [Progress Manager Functions](#)
- [Application-Defined Functions](#)

The header file `Progress.h` declares the API that this chapter describes. For more information on the progress manager, see the section “[Progress Dialogs](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Progress Manager Functions

### PrgHandleEvent

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                         |                       |                                                                             |                        |                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|-----------------------------------------------------------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>         | Handles events related to the active progress dialog.                                                                                                                                                                                                                                                                                                                                                                                   |                       |                                                                             |                        |                                                                                                                                                                                                                                 |
| <b>Declared In</b>     | <code>Progress.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                 |                       |                                                                             |                        |                                                                                                                                                                                                                                 |
| <b>Prototype</b>       | <code>Boolean PrgHandleEvent (ProgressPtr prgGP, EventType *eventP)</code>                                                                                                                                                                                                                                                                                                                                                              |                       |                                                                             |                        |                                                                                                                                                                                                                                 |

| -> <code>eventP</code> | Pointer to an event. You can pass a NULL event to cause this function to immediately call your <a href="#">PrgCallbackFunc</a> function and then update the dialog (for example, after you call <code>PrgUpdateDialog</code> ).                                                                                                                                                                                                         |                       |                                                                             |                        |                                                                                                                                                                                                                                 |
| <b>Result</b>          | Returns <code>true</code> if the system handled the event. If it returns <code>false</code> , you should check if the user canceled the dialog by calling <a href="#">PrgUserCancel</a> .                                                                                                                                                                                                                                               |                       |                                                                             |                        |                                                                                                                                                                                                                                 |

## Progress Manager

### Progress Manager Functions

---

**Comments** Use this function instead of [SysHandleEvent](#) when you have a progress dialog. `PrgHandleEvent` internally calls `SysHandleEvent` as needed.

Note that the auto power-off feature of the system is automatically disabled when you use this function, unless the dialog is just displaying an error. This function also prevents `appStopEvent` events.

If an update to the dialog is pending (from a call to [PrgUpdateDialog](#), for example) this function handles that event and causes the dialog to be updated. As part of this process, the `textCallback` function you specified in your call to [PrgStartDialog](#) is called. Your `textCallback` function should set the `textP` buffer in the `PrgCallbackData` structure with the new message to be displayed in the progress dialog. Optionally, you can also set the `bitmapId` field to include an icon in the update dialog. For more information about the `textCallback` function, see the section "[Application-Defined Functions](#)."

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [PrgStartDialog](#), [PrgStopDialog](#), [PrgUpdateDialog](#), [PrgUserCancel](#)

## PrgStartDialog

**Purpose** Displays a progress dialog that can be updated.

**Declared In** `Progress.h`

**Prototype** `ProgressPtr PrgStartDialog (const Char *title, PrgCallbackFunc textCallback, void *userDataP)`

**Parameters**

|                              |                                                                                                                                         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>title</code>        | Pointer to a title for the progress dialog. Must be a null-terminated string that is no longer than <code>progressMaxTitle</code> (20). |
| -> <code>textCallback</code> | Pointer to a callback function that supplies the text and icons for the current progress state. See <a href="#">PrgCallbackFunc</a> .   |

-> userDataP      A pointer to data that you need to access in the callback function. This address gets passed directly to your function.

**Result**      A pointer to a progress structure. This pointer must be passed to other progress manager functions and **must** be released by calling [PrgStopDialog](#). NULL is returned if the system is unable to allocate the progress structure.

**Comments**      The dialog created by this function can be updated by another process via the [PrgUpdateDialog](#) function. The dialog can contain a Cancel or OK button. The initial dialog defaults to stage 0 and calls the `textCallback` function to get the initial text and icon data for the progress dialog.

This function saves the screen bits behind the progress dialog, and these are restored when you call `PrgStopDialog`. Because of this, you should minimize changes to the screen while the progress dialog is displayed, otherwise, the restored bits may not match with what is currently being displayed.

**Compatibility**      This version of the function is available only if [3.2 New Feature Set](#) is present. On earlier systems, `PrgStartDialog` has the prototype shown for [PrgStartDialogV31](#).

**See Also**      [PrgHandleEvent](#), [PrgStopDialog](#), [PrgUpdateDialog](#), [PrgUserCancel](#)

## Progress Manager

### *Progress Manager Functions*

---

## PrgStartDialogV31

- Purpose** Displays a progress dialog that can be updated.
- Declared In** `Progress.h`
- Prototype** `ProgressPtr PrgStartDialogV31 (const Char *title, PrgCallbackFunc textCallback)`
- Parameters**
- > `title` Pointer to a title for the progress dialog. Must be a null-terminated string that is no longer than `progressMaxTitle` (20).
  - > `textCallback` Pointer to a callback function that supplies the text and icons for the current progress state. See [PrgCallbackFunc](#).
- Result** A pointer to a progress structure. This pointer must be passed to other progress manager functions and **must** be released by calling [PrgStopDialog](#). NULL is returned if the system is unable to allocate the progress structure.
- Compatibility** This function corresponds to version of [PrgStartDialog](#) available on Palm OS<sup>®</sup> 3.0 and Palm OS 3.1.
- See Also** [PrgHandleEvent](#), [PrgStopDialog](#), [PrgUpdateDialog](#), [PrgUserCancel](#)

## PrgStopDialog

|                          |                                                                                                                                                                                                                                                                                                                                                              |                         |                                                                             |                          |                                                                                                                                                                |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|-----------------------------------------------------------------------------|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>           | Releases memory used by the progress dialog and restores the screen to its initial state.                                                                                                                                                                                                                                                                    |                         |                                                                             |                          |                                                                                                                                                                |

| <b>Comments</b>          | If the progress dialog is in a state where it is displaying an error message to the user, this function normally waits for the user to confirm the dialog before it removes the dialog. If you specify <code>true</code> for the <code>force</code> parameter, this causes the system to remove the dialog immediately.                                      |                         |                                                                             |                          |                                                                                                                                                                |

## PrgUserCancel

|                      |                                                                                                                                                                                                                                                                                                                                                         |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that returns <code>true</code> if the user cancelled the process via the progress dialog.                                                                                                                                                                                                                                                         |
| <b>Declared In</b>   | <code>Progress.h</code>                                                                                                                                                                                                                                                                                                                                 |
| <b>Prototype</b>     | <code>PrgUserCancel (prgP)</code>                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>    | <code>-&gt; prgP</code> Pointer to a progress structure ( <code>ProgressPtr</code> ) created by <a href="#">PrgStartDialog</a> .                                                                                                                                                                                                                        |
| <b>Result</b>        | Returns the value of the <code>cancel</code> field in the progress structure (as a <code>UInt16</code> ).                                                                                                                                                                                                                                               |
| <b>Comments</b>      | This is a macro you can use to check if the user cancelled the process. If the user did cancel, you can change the progress dialog text to something like “Cancelling,” or “Disconnecting,” or whatever is appropriate for your application. Then you should cancel the process, end the communication session, or do whatever processing is necessary. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                     |

| <b>Result</b>                      | Returns <code>true</code> if the progress dialog should be updated using the values you specified in the <code>PrgCallbackData</code> structure. If you specify <code>false</code> , the dialog is still updated, but with default status messages. (Returning <code>false</code> is not recommended.)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                 |                                                            |                                    |                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>                    | <p>This is a callback function that you specify when you call <a href="#">PrgStartDialog</a>. The callback function is called by <a href="#">PrgHandleEvent</a> when it needs current progress information to display in the progress dialog.</p> <p>The system passes this function one parameter, a pointer to a <code>PrgCallbackData</code> structure. Here are the important fields in that data structure (note that <code>-&gt;</code> indicates you set the field in the <code>textCallback</code> function):</p> <table><tr><td><code>&lt;- UInt16 stage</code></td><td>Current stage (passed from <code>PrgUpdateDialog</code>).</td></tr><tr><td><code>&lt;-&gt; Char *textP</code></td><td>Buffer to hold the text to display in the updated dialog. You might want to look up a message in a resource file, based on the value in the <code>stage</code> field. Also, you should append the additional text in the message field, to form the full string to display. Be sure to include a null terminator at the end of the string you return, and don't exceed the length in <code>textLen</code>.</td></tr></table> | <code>&lt;- UInt16 stage</code> | Current stage (passed from <code>PrgUpdateDialog</code> ). | <code>&lt;-&gt; Char *textP</code> | Buffer to hold the text to display in the updated dialog. `<- UInt16 textLen`      Maximum length of the text buffer `textP`. Note that this value is set for you by the caller. Be careful not to exceed this length in `textP`.

`<- Char *message`      Additional text to display in the dialog (from the `messageP` parameter to `PrgUpdateDialog`). This should be no longer than `progressMaxMessage` (128).

`<- Err error`      Current error (passed from the `err` parameter to `PrgUpdateDialog`).

`-> UInt16 bitmapId`      Resource ID of the bitmap to display in the progress dialog, if any.

`<- UInt16 canceled:1`      `true` if user has pressed the cancel button.

`<- UInt16 showDetails:1`      `true` if user pressed the down arrow button on the Palm™ device for more details. (Because this is a non-standard user interface technique, you shouldn't use this feature to display details that users need under normal conditions. It's more for debugging purposes.)

`-> UInt16 textChanged:1`      If `true`, then update text (defaults to `true`). You can set this to `false` to avoid an update to the text.

`<- UInt16 timedOut:1`      `true` if update caused by a timeout.

## Progress Manager

### Application-Defined Functions

---

<-> UInt32 timeout

Timeout in ticks to force next update. After this number of ticks, an update is automatically triggered (which sets the `timedOut` flag). You can use this feature to do a simple animation effect. Note that you must set the timeout for `EvtGetEvent` to a value that is equal to or less than this value, otherwise you won't get update events as frequently as you expect.

-> UInt16 delay:1

If `true`, delay for one second after updating the dialog. Use this value when you are displaying the final progress message so that users have a chance to see the message before the dialog closes. This field is available only if [3.2 New Feature Set](#) is present.

<- void \*userDataP

A pointer to any application-defined data that the function needs to access. You specify this pointer as a parameter to [PrgStartDialog](#) if the callback function needs to access some application data but does not have access to application globals. This field is available only if [3.2 New Feature Set](#) is present.

In this function, you should set the value of the `textP` buffer to the string you want to display in the progress dialog when it is updated. You can use the value in the `stage` field to look up a message in a string resource. You also might want to append the text in the `message` field to your base string. Typically, the `message` field would contain more dynamic information that depends on a user selection, such as a phone number, device name, or network identifier, etc.

For example, the `PrgUpdateDialog` function might have been called with a `stage` of 1 and a `messageP` parameter value of a phone number string, "555-1212". Based on the `stage`, you might find the string "Dialing" in a string resource, and append the phone number, to form the final text "Dialing 555-1212" that you place in the text buffer `textP`.

Keeping the static strings corresponding to various stages in a resource makes it easier to localize your application. More dynamic information can be passed in via the `messageP` parameter to `PrgUpdateDialog`.

---

**NOTE:** This function is called only if the parameters passed to `PrgUpdateDialog` have changed from the last time it was called. If `PrgUpdateDialog` is called twice with exactly the same parameters, the `textCallback` function is called only once.

---

# Scroll Bars

---

This chapter provides reference material for the scroll bar API.

- [Scroll Bar Data Structures](#)
- [Scroll Bar Resources](#)
- [Scroll Bar Functions](#)

The header file `ScrollBar.h` declares the API that this chapter describes. For more information on scroll bars, see the section “[Scroll Bars](#)” on page 137 in the *Palm OS Programmer’s Companion*, vol. I.

## Scroll Bar Data Structures

### ScrollBarAttrType

The `ScrollBarAttrType` bit field defines a scroll bar’s visible characteristics.

```
typedef struct {
    UInt16 usable      :    1;
    UInt16 visible     :    1;
    UInt16 highlighted :    1;
    UInt16 shown       :    1;
    UInt16 activeRegion:    4;
} ScrollBarAttrType;
```

#### Field Descriptions

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|---------------|---------------------------|-----------------|------------------------|-----------------------------------------------------|--------------------------|-------------------------------------------------------|---------------------|-----------------|
| <code>usable</code>       | If not set, the scroll bar object is not considered part of the current interface of the application, and it doesn't appear on screen.                                                                                                                                                                                                                                                                                                                                                                                 |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>visible</code>      | If set, the scroll bar is allowed to be displayed on the screen. If both <code>visible</code> and <code>shown</code> are <code>true</code> , then the scroll bar is actually displayed on the screen.                                                                                                                                                                                                                                                                                                                  |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>highlighted</code>  | <code>true</code> if either the up arrow or the down arrow is highlighted.                                                                                                                                                                                                                                                                                                                                                                                                                                             |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>shown</code>        | Set if the scroll bar is visible and if <code>maxValue &gt; minValue</code> . (See <a href="#">ScrollBarType</a> .)                                                                                                                                                                                                                                                                                                                                                                                                    |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>activeRegion</code> | The region of the scroll bar that is receiving the pen down events. Possible values are:<br><table><tr><td><code>sclUpArrow</code></td><td>The up arrow.</td></tr><tr><td><code>sclDownArrow</code></td><td>The down arrow.</td></tr><tr><td><code>sclUpPage</code></td><td>The region between the scroll car and the up arrow.</td></tr><tr><td><code>sclDownPage</code></td><td>The region between the scroll car and the down arrow.</td></tr><tr><td><code>sclCar</code></td><td>The scroll car.</td></tr></table> | <code>sclUpArrow</code> | The up arrow. | <code>sclDownArrow</code> | The down arrow. | <code>sclUpPage</code> | The region between the scroll car and the up arrow. | <code>sclDownPage</code> | The region between the scroll car and the down arrow. | <code>sclCar</code> | The scroll car. |
| <code>sclUpArrow</code>   | The up arrow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>sclDownArrow</code> | The down arrow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>sclUpPage</code>    | The region between the scroll car and the up arrow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>sclDownPage</code>  | The region between the scroll car and the down arrow.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |
| <code>sclCar</code>       | The scroll car.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                         |               |                           |                 |                        |                                                     |                          |                                                       |                     |                 |

#### ScrollBarPtr

The `ScrollBarPtr` type defines a pointer to a [ScrollBarType](#) structure.

```
typedef ScrollBarType *ScrollBarPtr;
```

You pass the `ScrollBarPtr` as an argument to all scroll bar functions. You can obtain the `ScrollBarPtr` using the function [FrmGetObjectPtr](#) in this way:

```
scrollBarPtr = FrmGetObjectPtr(frm,  
    FrmGetObjectIndex(frm, scrollBarID));
```

where `scrollBarID` is the resource ID assigned when you created the scroll bar.

## ScrollBarType

The `ScrollBarType` represents a scroll bar.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `ScrollBarType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {  
    RectangleType    bounds;  
    UInt16          id;  
    ScrollBarAttrType attr;  
    Int16           value;  
    Int16           minValue;  
    Int16           maxValue;  
    Int16           pageSize;  
    Int16           penPosInCar;  
    Int16           savePos;  
} ScrollBarType;
```

Your code should treat the `ScrollBarType` structure as opaque. Use the functions described in this chapter to retrieve and set each value. Do not attempt to change structure member values directly.

#### Field Descriptions

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bounds   | <p>Position (using absolute coordinates) and size (in pixels) of the scroll bar on the screen. For example, to access the bounds of an object in a form whose ID is <code>kObjectID</code>:</p> <pre>{ RectangleType rect; FormPtr formP = FrmGetActiveForm();  FrmGetObjectBounds (formP, FrmGetObjectIndex (formP, kObjectID), &amp;rect); }</pre>                                                                                                                                                                                                                                                                                        |
| id       | <p>ID value you specified when you created the scroll bar object.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| attr     | <p>Scroll bar's attributes. See <a href="#">ScrollBarAttrType</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| value    | <p>Current value of the scroll bar. This value is used to determine where to position the scroll car (the dark region in the scroll bar that indicates the position in the document). Access with <a href="#">SclGetScrollBar</a>.</p> <p>The number given is typically a number relative to <code>minValue</code> and <code>maxValue</code>. These values have nothing to do with any physical characteristics of the object that the scroll bar is attached to, such as the number of lines in the object.</p> <p>This value is typically set to 0 initially and then adjusted programmatically with <a href="#">SclSetScrollBar</a>.</p> |
| minValue | <p>Minimum value. When <code>value</code> equals <code>minValue</code>, the scroll car is positioned at the very top of the scrolling region. This value is typically 0. Access with <a href="#">SclGetScrollBar</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                   |

|              |                                                                                                                                                                                                                                                                                        |
|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxValue     | Maximum value. When value equals maxValue, the scroll car is positioned at the very bottom of the scrolling region. This value is typically set to 0 initially and then adjusted programmatically with <a href="#">Sc1SetScrollBar</a> . Access with <a href="#">Sc1GetScrollBar</a> . |
| pageSize     | Number of lines to scroll when user scrolls one page. Access with <a href="#">Sc1GetScrollBar</a> .                                                                                                                                                                                    |
| penPosInChar | Used internally.                                                                                                                                                                                                                                                                       |
| savePos      | Used internally.                                                                                                                                                                                                                                                                       |

## Scroll Bar Resources

The [Scroll Bar Resource](#) (tSCL) represents a scroll bar.

## Scroll Bar Functions

### **ScIDrawScrollBar**

|                      |                                                                                                                                              |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Draw a scroll bar.                                                                                                                           |
| <b>Declared In</b>   | ScrollBar.h                                                                                                                                  |
| <b>Prototype</b>     | <code>void ScIDrawScrollBar (ScrollBarType *bar)</code>                                                                                      |
| <b>Parameters</b>    | -> bar                      Pointer to a scroll bar structure (see <a href="#">ScrollBarType</a> ).                                          |
| <b>Result</b>        | Returns nothing.                                                                                                                             |
| <b>Comments</b>      | This function is called internally by <a href="#">ScISetScrollBar</a> and <a href="#">FrmDrawForm</a> . You rarely need to call it yourself. |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                          |

### **ScIGetScrollBar**

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Retrieve a scroll bar's current position, its range, and the size of a page.                                            |
| <b>Declared In</b> | ScrollBar.h                                                                                                             |
| <b>Prototype</b>   | <code>void ScIGetScrollBar (const ScrollBarType *bar, Int16 *valueP, Int16 *minP, Int16 *maxP, Int16 *pageSizeP)</code> |
| <b>Parameters</b>  | -> bar                      Pointer to a scroll bar structure (see <a href="#">ScrollBarType</a> ).                     |

|                             |                                                                                                                                          |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-valueP</code>    | A value representing the scroll car's current position. (The scroll car is the dark region that indicates the position in the document.) |
| <code>&lt;-minP</code>      | A value representing the top of the user interface object.                                                                               |
| <code>&lt;-maxP</code>      | A value representing the bottom of the user interface object.                                                                            |
| <code>&lt;-pageSizeP</code> | Pointer to size of a page (used when page scrolling).                                                                                    |

**Result** Returns the scroll bar's current values in `valueP`, `minP`, `maxP`, and `pageSizeP`.

**Comments** You might use this function immediately before calling [ScISetScrollBar](#) to update the scroll bar. `ScIGetScrollBar` returns the scroll bar's current values, which you can then adjust as necessary and pass to `ScISetScrollBar`.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [ScISetScrollBar](#)

## ScIHandleEvent

**Purpose** Handles events that affect a scroll bar.

**Declared In** `ScrollBar.h`

**Prototype** `Boolean ScIHandleEvent (ScrollBarType *bar, const EventType *event)`

**Parameters**

|                          |                                                                         |
|--------------------------|-------------------------------------------------------------------------|
| <code>-&gt; bar</code>   | Pointer to a scroll bar structure (see <a href="#">ScrollBarType</a> ). |
| <code>-&gt; event</code> | Pointer to an event ( <a href="#">EventType</a> ).                      |

**Result** Returns `true` if the event was handled.

## Scroll Bars

### Scroll Bar Functions

---

**Comment** When a [penDownEvent](#) occurs, the scroll bar sends an [sclEnterEvent](#) to the event queue.

When an `sclEnterEvent` occurs, the scroll bar determines what its new value should be based on which region of the scroll bar is receiving the pen down events. It then sends either an [sclRepeatEvent](#) or an [sclExitEvent](#) to the event queue.

When the user holds and drags the scroll bar with the pen, the scroll bar sends a [sclRepeatEvent](#). Applications that implement dynamic scrolling should catch this event and move the text each time one arrives.

When the user releases the pen from the scroll bar, the scroll bar sends a [sclExitEvent](#). Applications that implement non-dynamic scrolling should catch this event and move the text when `sclExitEvent` arrives. Applications that implement dynamic scrolling can ignore this event.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SclSetScrollBar

**Purpose** Set the scroll bar's current position, its range, and the size of a page. If the scroll bar is visible and its minimum and maximum values are not equal, it's redrawn.

**Declared In** `ScrollBar.h`

**Prototype** `void SclSetScrollBar (ScrollBarType *bar, Int16 value, Int16 min, Int16 max, Int16 pageSize)`

**Parameters**

|          |                                                                                                                              |
|----------|------------------------------------------------------------------------------------------------------------------------------|
| -> bar   | Pointer to a scroll bar structure (see <a href="#">ScrollBarType</a> ).                                                      |
| -> value | The position the scroll car should move to. (The scroll car is the dark region that indicates the position in the document.) |
| -> min   | Minimum value.                                                                                                               |
| -> max   | Maximum value.                                                                                                               |

-> `pageSize`      Number of lines of text that can be displayed on a the screen at one time (used when page scrolling).

**Result**      Returns nothing. May display a fatal error message if the `min` parameter is greater than the `max` parameter.

**Comments**      Call this function when the user adds or deletes text in a field or when a table row is added or deleted.

For scrolling fields, your application should catch the [fldChangedEvent](#) and update the scroll bar at that time.

The `max` parameter is computed as:

number of lines of text – page size + overlap

where number of lines of text is the total number of lines or rows needed to display the entire object, page size is the number of lines or rows that can be displayed on the screen at one time, and overlap is the number of lines or rows from the bottom of one page to be visible at the top of the next page.

For example, if you have 100 lines of text and 10 lines show on a page, the `max` value would be 90 or 91, depending on the overlap. So if value is greater than or equal to 90 or 91, the scroll car is at the very bottom of the scrolling region.

You can use the [FldGetScrollValues](#) function to compute the values you pass for `value`, `min`, and `max`. For example:

```
FldGetScrollValues (fld, &scrollPos,  
                  &textHeight, &fieldHeight);  
  
if (textHeight > fieldHeight)  
    maxValue = textHeight - fieldHeight;  
else if (scrollPos)  
    maxValue = scrollPos;  
else  
    maxValue = 0;  
  
ScISetScrollBar (bar, scrollPos, 0, maxValue,  
                fieldHeight-1);
```

## Scroll Bars

### *Scroll Bar Functions*

---

In this case, `textHeight` is the number of lines of text and `fieldHeight` is the page size. No lines overlap when you scroll one page. Notice that if the page size is greater than the lines of text, then `max` equals `min`, which means that the scroll bar is not displayed.

For scrolling tables, there is no equivalent to `FldGetScrollValues`. Your application must scroll the table itself and keep track of the scroll values. See the `ListViewUpdateScrollers` function in the Memo example application (`MemoMain.c`) for an example of setting scroll bar values for a table.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [ScIGetScrollBar](#)

## **Scroll Bars**

### *Scroll Bar Functions*

---

# System Dialogs

---

This chapter provides reference material for system dialogs declared in the header files `FatalAlert.h`, `Launcher.h`, `GraffitiReference.h`, and `GraffitiUI.h`.

## System Dialog Functions

### SysAppLauncherDialog

**Purpose** Display the launcher popup, get a choice, ask the system to launch the selected application, clean up, and leave. If there are no applications to launch, nothing happens.

**Declared In** `Launcher.h`

**Prototype** `void SysAppLauncherDialog()`

**Parameters** None.

**Result** The system may be asked to launch an application.

**Comments** Typically, this routine is called by the system as necessary. Most applications do not need to call this function themselves.

In Palm OS® version 3.0 and higher the launcher is an application, rather than a popup. This function remains available for compatibility purposes only.

**See Also** [SysAppLaunch](#), the “[Application Launcher](#)” section in the *Palm OS Programmer’s Companion*, vol. I

## **SysFatalAlert**

- Purpose** Display a fatal alert until the user taps a button in the alert.
- Declared In** FatalAlert.h
- Prototype** `UInt16 SysFatalAlert (const Char *msg)`
- Parameters** `msg` Message to display in the dialog.
- Result** The button tapped; first button is zero.

## **SysGraffitiReferenceDialog**

- Purpose** Pop up the Graffiti® Reference Dialog.
- Declared In** GraffitiReference.h
- Prototype** `void SysGraffitiReferenceDialog (ReferenceType referenceType)`
- Parameters** `referenceType` Which reference to display. See `GraffitiReference.h` for more information.
- Result** Nothing returned.

# Tables

---

This chapter describes the table API as declared in the header file `Table.h`. It discusses the following topics:

- [Table Data Structures](#)
- [Table Constants](#)
- [Table Resource](#)
- [Table Functions](#)
- [Application-Defined Functions](#)

For more information on tables, see the section “[Tables](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Table Data Structures

### TableAttrType

The `TableAttrType` bit field defines the visible characteristics of the table.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `TableAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16 visible:1;
    UInt16 editable:1;
```

## Tables

### Table Data Structures

---

```
    UInt16 editing:1;
    UInt16 selected:1;
    UInt16 hasScrollBar:1;
    UInt16 reserved:11;
} TableAttrType;
```

Your code should treat the `TableAttrType` bit field as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change member values directly.

#### Field Descriptions

|                           |                                                                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>visible</code>      | If set, the table is drawn on the screen. The value of this field is set by <a href="#">TblDrawTable</a> and cleared by <a href="#">TblEraseTable</a> .                                                           |
| <code>editable</code>     | If set, the user can modify the table. You specify this when you create the table resource.                                                                                                                       |
| <code>editing</code>      | If set, the table is in edit mode. The table is in edit mode while the user edits a text item. The value of this field is returned by <a href="#">TblEditing</a> .                                                |
| <code>selected</code>     | If set, the current item (as identified by the <a href="#">TableType</a> fields <code>currentRow</code> and <code>currentColumn</code> ) is selected. Use <a href="#">TblGetSelection</a> to retrieve this value. |
| <code>hasScrollBar</code> | If set, the table has a scroll bar. Note that this attribute can only be set programmatically. See <a href="#">TblHasScrollBar</a> .                                                                              |

#### TableColumnType

The `TableColumnType` structure defines a column in a table.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `TableColumnType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```

typedef struct {
    Coord                width;
    UInt16               reserved1 : 5;
    UInt16               masked : 1;
    UInt16               editIndicator : 1;
    UInt16               usable : 1;
    UInt16               reserved2 : 8;
    Coord               spacing;
    TableDrawItemFuncPtr drawCallback;
    TableLoadDataFuncPtr loadDataCallback;
    TableSaveDataFuncPtr saveDataCallback;
} TableColumnAttrType;
    
```

Your code should treat the `TableColumnAttrType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

**Field Descriptions**

|                            |                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>width</code>         | The column's width in pixels. See <a href="#">TblGetColumnWidth</a> and <a href="#">TblSetColumnWidth</a> .                                                                                                                                                                                                                                                         |
| <code>reserved1</code>     | Reserved for future use.                                                                                                                                                                                                                                                                                                                                            |
| <code>masked</code>        | If <code>true</code> and the item's row also has a <code>masked</code> attribute of <code>true</code> , the table cell is drawn on the screen but is shaded to obscure the information that it contains. See <a href="#">TblSetColumnMasked</a> .                                                                                                                   |
| <code>editIndicator</code> | If <code>true</code> , items in the column should be highlighted if selected while in edit mode. If <code>false</code> , items in the column should not be highlighted. By default, text field items are highlighted in edit mode, but all other types of items are not highlighted. The default can be overridden with <a href="#">TblSetColumnEditIndicator</a> . |

## Tables

### Table Data Structures

---

|                  |                                                                                                                                                                                                               |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| usable           | If false, the column is not considered part of the current interface of the application, and it doesn't appear on screen. See <a href="#">TblSetColumnUsable</a> .                                            |
| reserved2        | Reserved for future use.                                                                                                                                                                                      |
| spacing          | The spacing in pixels between this column and the next column. See <a href="#">TblGetColumnSpacing</a> and <a href="#">TblSetColumnSpacing</a> .                                                              |
| drawCallback     | Pointer to a function that draws custom items in the column. This function is called during <a href="#">TblDrawTable</a> and <a href="#">TblRedrawTable</a> . See <a href="#">TblSetCustomDrawProcedure</a> . |
| loadDataCallback | Pointer to a function that loads data into the column. This function is called during <a href="#">TblDrawTable</a> and <a href="#">TblRedrawTable</a> . See <a href="#">TblSetLoadDataProcedure</a> .         |
| saveDataCallback | Pointer to a function that saves the data in the column. Called when the focus moves from one table cell to another and when the table loses focus entirely. See <a href="#">TblSetSaveDataProcedure</a> .    |

**Compatibility** The masked field is defined only if [3.5 New Feature Set](#) is present.

### TableItemPtr

A `TableItemPtr` points to a [TableItemType](#).

```
typedef TableItemType *TableItemPtr;
```

### TableItemType

The `TableItemType` structure defines an item, or cell, within the table.

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `TableItemType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    TableItemStyleType  itemType;
    FontID              fontID;
    Int16               intValue;
    Char                *ptr;
} TableItemType;
```

Your code should treat the `TableItemType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

---

**NOTE:** None of the table items create memory that you need to free. The table manager handles all of the allocating and deallocating of memory for table items. The only memory you are responsible for freeing is the memory handle containing the text that you want displayed in editable text fields. (See [TableLoadDataFuncType](#).)

---

### Field Descriptions

|                       |                                                                                                                                                                                                                                                                |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>itemType</code> | The type of the item, such as a control, a text label, and so on. <a href="#">TblSetItemStyle</a> sets this value. The rest of the fields in this struct are either used or not used depending on the <code>itemType</code> . See <a href="#">Table 20.1</a> . |
| <code>fontID</code>   | ID of the font used to display the item's text. <a href="#">TblGetItemFont</a> and <a href="#">TblSetItemFont</a> retrieve and set this value.                                                                                                                 |

## Tables

### Table Data Structures

---

`intValue` Integer value of the item. [TblGetItemInt](#) and [TblSetItemInt](#) retrieve and set this value.

`ptr` Pointer to the item's text. [TblGetItemPtr](#) and [TblSetItemPtr](#) retrieve and set this value. All text items have a maximum of `tableMaxTextItemSize`.

The following table lists the possible values for the `itemType` field, describes how each type is drawn, describes which other fields are used for each `itemType`, and provides special instructions for setting those fields. Note in particular that the `fontID` field is often not used. Instead, certain items are displayed in a standard font. These are noted in the last column of this table.

**Table 20.1 TableItem fields**

| ItemType                       | Description                                                                                                                                      | TableItem Fields Used                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>checkboxTableItem</code> | A checkbox control.                                                                                                                              | <code>intValue</code>                                                                                                                                                                                                                                                                                                                                                                          |
| <code>customTableItem</code>   | Application-defined cell. The height of the item is fixed at 11 pixels.                                                                          | None.<br>Custom items are drawn using the custom drawing function that you implement. See <a href="#">TableDrawItemFuncType</a> . If you want, you can store data in the <code>intValue</code> and <code>ptr</code> fields.                                                                                                                                                                    |
| <code>dateTableItem</code>     | Non-editable date in the form <i>month/day</i> , or a dash if the date value is -1. The date is followed by an exclamation point if it has past. | <code>intValue</code><br>The <code>intValue</code> field should be a value that can be cast to <code>DateType</code> . <code>DateType</code> is currently defined as a 16-bit number:<br><code>yyyyyyymmdd</code><br>The first 7 bits are the year given as the offset since 1904, the next 4 bits are the month, and the next 5 bits are the day. Dates are always drawn in the current font. |

**Table 20.1 TableItem fields (*continued*)**

| <b>ItemType</b>       | <b>Description</b>                                                                                                                                                                                                                      | <b>TableItem Fields Used</b>                                                                                                                                                                      |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| labelTableItem        | Non-editable text.                                                                                                                                                                                                                      | ptr<br>Labels are displayed in the system's default font along with a terminating colon character (':'). Use a customTableItem or tallCustomTableItem if you don't want a colon.                  |
| numericTableItem      | Non-editable number.                                                                                                                                                                                                                    | intValue<br>Numbers are displayed in the system's default bold font.                                                                                                                              |
| popupTriggerTableItem | A list with a pop-up trigger.                                                                                                                                                                                                           | intValue<br>ptr<br>intValue is the index of the list item that should be displayed.<br>ptr is a pointer to the list.<br>Lists are displayed in the system's default font.                         |
| tallCustomTableItem   | Application-defined cell. The height of the item is equal to the height of the row in which the item is located. This table item type was added in Palm OS 4.0 and is only supported if <a href="#">4.0 New Feature Set</a> is defined. | None.<br>Custom items are drawn using the custom drawing function that you implement. See <a href="#">TableDrawItemFuncType</a> . If you want, you can store data in the intValue and ptr fields. |

## Tables

### Table Data Structures

---

**Table 20.1 TableItemType fields (*continued*)**

| <b>ItemType</b>       | <b>Description</b>                                            | <b>TableItemType Fields Used</b>                                                                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| textTableItem         | Editable text field.                                          | fontID<br>ptr<br>For this item type, implement the callback function <a href="#">TableLoadDataFuncType</a> to load text into the table cell and implement the callback <a href="#">TableSaveDataFuncType</a> to save data before the field is freed. |
| textWithNoteTableItem | Editable text field and a note icon to the right of the text. | fontID<br>ptr<br>For this item type, implement the callback function <a href="#">TableLoadDataFuncType</a> to load text into the table cell and implement the callback <a href="#">TableSaveDataFuncType</a> to save data before the field is freed. |

**Table 20.1 TableItem fields (*continued*)**

| ItemType            | Description                                                      | TableItem Fields Used                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------|------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| timeTableItem       | Not implemented.                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| narrowTextTableItem | Editable text with space reserved on the right side of the cell. | fontID<br>ptr<br>intValue<br>intValue is the number of pixels to reserve on the right side of the cell.<br>For this item type, implement the callback function <a href="#">TableDrawItemFuncType</a> to draw in the space reserved on the right side of the cell, the <a href="#">TableLoadDataFuncType</a> callback function to load text into the table cell, and the callback function <a href="#">TableSaveDataFuncType</a> to save data before the field is freed. |

## TablePtr

The TablePtr type defines a pointer to a [TableType](#).

```
typedef TableType *TablePtr;
```

You pass the table's pointer as an argument to all table functions. You can obtain the table's pointer using the function [FrmGetObjectPtr](#) in this way:

```
tblPtr = FrmGetObjectPtr(frm,  
    FrmGetObjectIndex(frm, tblID));
```

where tblID is the resource ID assigned when you created the table.

## Tables

### Table Data Structures

---

## TableRowAttrType

The `TableRowAttrType` structure defines a row in a table.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `TableRowAttrType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct {
    UInt16      id;
    Coord       height;
    UInt32      data;
    UInt16      reserved1 : 7;
    UInt16      usable : 1;
    UInt16      reserved2 : 4;
    UInt16      masked : 1;
    UInt16      invalid : 1;
    UInt16      staticHeight : 1;
    UInt16      selectable : 1;
    UInt16      reserved3;
} TableRowAttrType;
```

Your code should treat the `TableRowAttrType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

### Field Descriptions

|                     |                                                                                                                                             |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <code>id</code>     | The ID of this row. See <a href="#">TblFindRowID</a> , <a href="#">TblGetRowID</a> , and <a href="#">TblSetRowID</a> .                      |
| <code>height</code> | Height of the row in pixels. The functions <a href="#">TblSetRowHeight</a> and <a href="#">TblGetRowHeight</a> set and retrieve this value. |

|              |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| data         | Any application-specific value you want to store in this row. For example, the Datebook and ToDo applications use this field to store the unique ID of the database record that is displayed in this table row. See <a href="#">TblFindRowData</a> , <a href="#">TblGetRowData</a> , and <a href="#">TblSetRowData</a> .                                                                                                    |
| reserved1    | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                    |
| usable       | If <code>false</code> , the row is not considered part of the current interface of the application, and it doesn't appear on screen. Table rows have <code>usable</code> set to <code>false</code> when they are scrolled off the screen. See <a href="#">TblRowUsable</a> and <a href="#">TblSetRowUsable</a> . The function <a href="#">TblGetLastUsableRow</a> returns the row that appears at the bottom of the screen. |
| masked       | If <code>true</code> and the item's column also has a <code>masked</code> attribute of <code>true</code> , the table cell is drawn on the screen but is shaded to obscure the information that it contains. See <a href="#">TblSetRowMasked</a> and <a href="#">TblRowMasked</a> .                                                                                                                                          |
| reserved2    | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                    |
| invalid      | If <code>true</code> , the row needs to be redrawn. See <a href="#">TblRowInvalid</a> , <a href="#">TblMarkRowInvalid</a> , and <a href="#">TblMarkTableInvalid</a> .                                                                                                                                                                                                                                                       |
| staticHeight | <code>true</code> if the row height cannot be changed, <code>false</code> otherwise. If <code>false</code> , text fields in this table row will dynamically resize to multiple lines as necessary. See <a href="#">TblSetRowStaticHeight</a> .                                                                                                                                                                              |
| selectable   | If <code>true</code> , the user can select individual cells in this row. See <a href="#">TblSetRowSelectable</a> and <a href="#">TblRowSelectable</a> .                                                                                                                                                                                                                                                                     |
| reserved3    | Reserved for future use.                                                                                                                                                                                                                                                                                                                                                                                                    |

**Compatibility** The `masked` field is defined only if [3.5 New Feature Set](#) is present.

## Tables

### Table Data Structures

---

## TableType

The `TableType` structure represents a table.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `TableType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct TableType {
    UInt16          id;
    RectangleType   bounds;
    TableAttrType   attr;
    Int16           numColumns;
    Int16           numRows;
    Int16           currentRow;
    Int16           currentColumn;
    Int16           topRow;
    TableColumnType *columnAttrs;
    TableRowAttrType *rowAttrs;
    TableItemPtr    items;
    FieldType       currentField;
} TableType;
```

Your code should treat the `TableType` structure as opaque. Use the functions specified in the descriptions below to retrieve and set each value. Do not attempt to change structure member values directly.

### Field Descriptions

|                     |                                                                                                                                                                                                                             |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>id</code>     | ID value you specified when you created the table resource. This ID is included as part of the event data of <a href="#">tblEnterEvent</a> .                                                                                |
| <code>bounds</code> | Position and size of the table object. The functions <a href="#">TblGetBounds</a> , <a href="#">FrmGetObjectBounds</a> , <a href="#">TblSetBounds</a> , and <a href="#">FrmSetObjectBounds</a> retrieve and set this value. |

|                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>attr</code>          | The table's attributes. See <a href="#">TableAttrType</a> .                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>numColumns</code>    | Number of columns displayed by the table object. You specify the number of columns when you create the table resource, and this value cannot be changed. Access with <a href="#">TblGetNumberOfColumns</a> .                                                                                                                                                                                                                                                |
| <code>numRows</code>       | Maximum number of visible rows in the table object.<br>You specify this value when you create the table resource, and it does not change; however, the total number of rows in a table can change if you insert new rows in a table, and even the number of currently visible rows can change if a text field within a table cell is dynamically resized.<br>The function <a href="#">TblGetNumberOfRows</a> returns the value of this field.               |
| <code>currentRow</code>    | Row index of the currently selected table cell. Rows are numbered from top to bottom starting with 0. <a href="#">TblGetSelection</a> and <a href="#">TblSetSelection</a> retrieve and set the values of <code>currentRow</code> .                                                                                                                                                                                                                          |
| <code>currentColumn</code> | Column index of the currently selected table cell. Columns are numbered from left to right starting with 0. If the <a href="#">TableAttrType</a> selected is <code>true</code> , then this table cell is highlighted. If <code>false</code> , the table still considers this the "current" item, but it is not highlighted. <a href="#">TblGetSelection</a> and <a href="#">TblSetSelection</a> retrieve and set the values of <code>currentColumn</code> . |
| <code>topRow</code>        | First visible row of the table object. Access with <a href="#">TblGetTopRow</a> .                                                                                                                                                                                                                                                                                                                                                                           |
| <code>columnAttrs</code>   | An array of each table column's attributes. See <a href="#">TableColumnAttrType</a> .                                                                                                                                                                                                                                                                                                                                                                       |

## Tables

### Table Constants

---

|                           |                                                                                                                                                                   |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rowAttrs</code>     | An array of each row's attributes, such as its ID, height, and whether or not it is usable, selectable, or invalid. See <a href="#">TableRowAttrType</a> .        |
| <code>items</code>        | An array of each item's (table cell's) attributes, such as the item type, font ID, an integer value, and a character pointer. See <a href="#">TableItemType</a> . |
| <code>currentField</code> | Field object the user is currently editing. The function <a href="#">TblGetCurrentField</a> retrieves the value of this item.                                     |

## Table Constants

---

| Constant                               | Value  | Description                                                                                                                                           |
|----------------------------------------|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>tableDefaultColumnSpacing</code> | 1      | Never used.                                                                                                                                           |
| <code>tableNoteIndicatorHeight</code>  | 11     | The height in pixels of the note indicator for tables items of type <code>textWithNoteTableItem</code> .                                              |
| <code>tableNoteIndicatorWidth</code>   | 7      | The width in pixels of the note indicator for tables items of type <code>textWithNoteTableItem</code> .                                               |
| <code>tableMaxTextItemSize</code>      | 255    | The maximum length of an editable text field within a table cell.                                                                                     |
| <code>tblUnusableRow</code>            | 0xffff | Value returned by <a href="#">TblGetLastUsableRow</a> if none of the table's rows are usable. This value is only available in version 3.5 and higher. |

---

## Table Resource

The [Table Resource](#) (tTBL) represents a table on screen.

## Table Functions

### TblDrawTable

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a table.                                                                                         |
| <b>Declared In</b> | Table.h                                                                                               |
| <b>Prototype</b>   | <code>void TblDrawTable (TableType *tableP)</code>                                                    |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)                |
| <b>Result</b>      | Returns nothing.                                                                                      |
| <b>Comments</b>    | This function is called as part of <a href="#">FrmDrawForm</a> when the form contains a table object. |

This function draws the entire table, marking all rows valid before drawing. See the [TableItemType](#) struct description for more information about how each type of table cell is drawn.

When drawing cells with editable text fields (`textTableItem`, `textWithNoteTableItem`, or `narrowTextTableItem`), this function uses the [TableLoadDataFuncType](#) callback function to load the text into the table cells. The text field does not retain the text handle that your `TableLoadDataFunc` returns, meaning that you are responsible for freeing the memory that you load into the table.

When drawing `narrowTextTableItem` cells, `customTableItem` cells or `tallCustomTableItem` cells, this function uses the [TableDrawItemFuncType](#) callback function to draw the extra pixels after the text or to draw the entire cell.

On color systems, tables are always drawn using the same color as is used for the field background color.

When the user has set the security setting to mask private records, table cells that contain private database records are drawn as shaded cells to obscure the information they contain. You must explicitly tell the table which cells are masked by making the

## Tables

### Table Functions

---

appropriate calls to [TblSetRowMasked](#) and [TblSetColumnMasked](#).

**Compatibility** Color support and masked private records are only supported in Palm OS® version 3.5 and higher.

In versions earlier than 3.5, this function did not erase table cells before it drew them. In earlier releases, consider calling [TblEraseTable](#) before calling this function, particularly if the entire table has changed, as the visual effect of drawing over a white background may be more pleasing.

**See Also** [TblEraseTable](#), [TblRedrawTable](#), [TblSetCustomDrawProcedure](#)

## TblEditing

**Purpose** Check whether a table is in edit mode.

**Declared In** `Table.h`

**Prototype** `Boolean TblEditing (const TableType *tableP)`

**Parameters** `-> tableP` Pointer to a table object. (See [TableType](#).)

**Result** Returns `true` if the table is in edit mode, `false` otherwise.

**Comments** The table is in edit mode while the user edits a text item. More specifically, the table is in edit mode when a [tblEnterEvent](#) is received on an editable table cell (`textTableItem`, `textWithNoteTableItem`, or `narrowTextTableItem`), or when [TblGrabFocus](#) is called.

The table is taken out of edit mode when a the user places the pen on a note in a `textWithNoteTableItem` or when the table releases the focus ([TblReleaseFocus](#)).

## TblEraseTable

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Erase a table object.                                                                                        |
| <b>Declared In</b> | Table.h                                                                                                      |
| <b>Prototype</b>   | <code>void TblEraseTable (TableType *tableP)</code>                                                          |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)                            |
| <b>Result</b>      | Returns nothing.                                                                                             |
| <b>Comments</b>    | This function sets the table's visible and selected attributes to false. It does not invalidate table rows.  |
| <b>See Also</b>    | <a href="#">TblDrawTable</a> , <a href="#">TblSetCustomDrawProcedure</a> ,<br><a href="#">TblRedrawTable</a> |

## TblFindRowData

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the number of the row that contains the specified data value.                                                                                                                          |
| <b>Declared In</b> | Table.h                                                                                                                                                                                       |
| <b>Prototype</b>   | <code>Boolean TblFindRowData (const TableType *tableP, UInt32 data, Int16 *rowP)</code>                                                                                                       |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)<br>-> data              Row data to find.<br><- rowP              Pointer to the row number (return value). |
| <b>Result</b>      | Returns true if a match was found, false otherwise.                                                                                                                                           |

## Tables

### Table Functions

---

**Comments** This function searches for a row whose attributes contain the specified data. The data is any application-specific data that you have set with [TblSetRowData](#).

**See Also** [TblGetRowData](#), [TblFindRowID](#), [TableRowAttrType](#)

## TblFindRowID

**Purpose** Return the number of the row with the specified ID.

**Declared In** `Table.h`

**Prototype** `Boolean TblFindRowID (const TableType *tableP, UInt16 id, Int16 *rowP)`

**Parameters**

|           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> id     | Row ID to find.                                              |
| <- rowP   | Pointer to the row number (return value).                    |

**Result** Returns `true` if a match was found, `false` otherwise.

**See Also** [TblSetRowID](#), [TblFindRowData](#), [TableRowAttrType](#)

## TblGetBounds

**Purpose** Return the bounds of a table.

**Declared In** `Table.h`

**Prototype** `void TblGetBounds (const TableType *tableP, RectangleType *rP)`

**Parameters**

|           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
|-----------|--------------------------------------------------------------|

<- rP                      A `RectangleType` structure in which the bounds are returned.

**Result**                  Returns nothing. The `rP` parameter contains the bounds.

**See Also**                [TblGetItemBounds](#)

## **TblGetColumnSpacing**

**Purpose**                  Return the spacing after the specified column.

**Declared In**            `Table.h`

**Prototype**             `Coord TblGetColumnSpacing  
(const TableType *tableP, Int16 column)`

**Parameters**            -> `tableP`                Pointer to a table object. (See [TableType](#).)  
                         -> `column`                Column number (zero-based).

**Result**                  Returns the spacing after `column` (in pixels).  
  
This function may display a fatal error message if the `column` parameter is invalid.

**See Also**                [TblGetColumnWidth](#), [TblSetColumnSpacing](#),  
[TblSetColumnUsable](#)

## **TblGetColumnWidth**

**Purpose**                  Return the width of the specified column.

**Declared In**            `Table.h`

**Prototype**             `Coord TblGetColumnWidth (const TableType *tableP,  
Int16 column)`

**Parameters**            -> `tableP`                Pointer to a table object. (See [TableType](#).)

## Tables

### Table Functions

---

-> column            Column number (zero-based).

**Result**        Returns the width of a column (in pixels). This function may display a fatal error message if the `column` parameter is invalid.

**See Also**        [TblGetColumnSpacing](#), [TblSetColumnWidth](#),  
[TblSetColumnUsable](#)

### TblGetCurrentField

**Purpose**         Return a pointer to the [FieldType](#) in which the user is currently editing a text item.

**Declared In**    `Table.h`

**Prototype**     `FieldPtr TblGetCurrentField  
(const TableType *tableP)`

**Parameters**    -> `tableP`            Pointer to a table object. (See [TableType](#).)

**Result**         Returns a pointer to the currently selected field, or `NULL` if the table is not in edit mode.

**See Also**        [TblGetSelection](#)

### TblGetItemBounds

**Purpose**         Return the bounds of an item in a table.

**Declared In**    `Table.h`

**Prototype**     `void TblGetItemBounds (const TableType *tableP,  
Int16 row, Int16 column, RectangleType *rP)`

**Parameters**    -> `tableP`            Pointer to a table object. (See [TableType](#).)  
                  -> `row`                 Row number of the item (zero-based).  
                  -> `column`            Column number of the item (zero-based).

<- rP                      Pointer to a structure that holds the bounds of the item.

**Result**                  Returns nothing. Stores the bounds in rP. This function may raise a fatal exception if the row or column parameter specifies a row or column that does not appear on screen.

## TblGetItemFont

**Purpose**                    Return the font used to display a table item.

**Declared In**              Table.h

**Prototype**                FontID TblGetItemFont (const TableType \*tableP, Int16 row, Int16 column)

**Parameters**              -> tableP                  Pointer to a table object. (See [TableType](#).)  
                              -> row                        Row number of the item (zero-based).  
                              -> column                  Column number of the item (zero-based).

**Result**                    Returns the ID of the font used for the table item at the row and column indicated. This function may display a fatal error message if the row or column parameter specifies a row or column that is not on the screen.

**Comments**                This function returns the value stored in the fontID field for this table item. Only certain types of table items use the font specified by the fontID field when they are displayed. The [TableItemType](#) description specifies what font is used to display each type of table item.

**Compatibility**            Implemented only if [3.0 New Feature Set](#) is present.

**See Also**                  [TblSetItemFont](#)

## Tables

### Table Functions

---

#### TblGetItemInt

- Purpose** Return the integer value stored in a table item.
- Declared In** `Table.h`
- Prototype**  
`Int16 TblGetItemInt (const TableType *tableP,  
Int16 row, Int16 column)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `row` Row number of the item (zero-based).
  - > `column` Column number of the item (zero-based).
- Result** Returns the integer value. This function may display a fatal message if the row or column does not appear on the screen.
- Comments** This function returns the value stored in the `intValue` field for this table item. Certain types of table items display the value stored in `intValue`, and other types display the value pointed to by the `ptr` field. See the [TableItemType](#) description for details. If the `intValue` was never set for this table item, this function returns 0.
- See Also** [TblSetItemInt](#), [TblGetItemPtr](#)

#### TblGetItemPtr

- Purpose** Return the pointer value stored in a table item
- Declared In** `Table.h`
- Prototype**  
`void *TblGetItemPtr (const TableType *tableP,  
Int16 row, Int16 column)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `row` Row number of the item (zero-based).

-> column            Column number of the item (zero-based).

**Result**            Returns the item's pointer value or NULL if the item does not have a pointer value. This function may display a fatal message if the row or column parameter is invalid.

**Comments**        This function returns the value stored in the ptr field for this table item. Certain types of table items display the value pointed to by the ptr, and other types display the value stored in the intValue field. See the [TableItemType](#) description for details. An application may have set the value of the ptr field anyway, even for items that use the intValue. This function always returns that value.

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present. In earlier versions, you can implement this function using the following code:

```
return tableP->items[row * tableP->numColumns +
        column].ptr;
```

**See Also**        [TblSetItemPtr](#)

## **TblGetLastUsableRow**

**Purpose**            Return the last row in a table that is usable (visible).

**Declared In**     Table.h

**Prototype**        Int16 TblGetLastUsableRow  
                  (const TableType \*tableP)

**Parameters**     -> tableP            Pointer to a table object. (See [TableType](#).)

**Result**            Returns the row index (zero-based) or tblUnusableRow if there are no usable rows.

**See Also**        [TblGetRowData](#), [TblGetRowID](#)

#### TblGetNumberOfColumns

|                      |                                                                                                                                                                                                                                                                                                      |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the number of columns in a table.                                                                                                                                                                                                                                                             |
| <b>Declared In</b>   | Table.h                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>     | <pre>Int16 TblGetNumberOfColumns (const TableType *tableP)</pre>                                                                                                                                                                                                                                     |
| <b>Parameters</b>    | -> tableP            Pointer to a <a href="#">TableType</a> .                                                                                                                                                                                                                                        |
| <b>Result</b>        | This function returns the number of columns in a table.                                                                                                                                                                                                                                              |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TblGlueGetNumberOfColumns. For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a> |
| <b>See Also</b>      | <a href="#">TblGetTopRow</a> , <a href="#">TblSetSelection</a>                                                                                                                                                                                                                                       |

#### TblGetNumberOfRows

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the number of rows in a table.                                                                                                                                                           |
| <b>Declared In</b> | Table.h                                                                                                                                                                                         |
| <b>Prototype</b>   | <pre>Int16 TblGetNumberOfRows (const TableType *tableP)</pre>                                                                                                                                   |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)                                                                                                               |
| <b>Result</b>      | Returns the maximum number of visible rows in the specified table.                                                                                                                              |
| <b>Comments</b>    | Note that even though you can add and remove rows to and from a table, the value returned by this function does not change. The value returned by this function indicates the maximum number of |

rows that can be displayed on the screen at one time. It is set when you create the table resource.

## TblGetRowData

|                    |                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the data value of the specified row.                                                                                                                                                                             |
| <b>Declared In</b> | Table.h                                                                                                                                                                                                                 |
| <b>Prototype</b>   | UInt32 TblGetRowData (const TableType *tableP,<br>Int16 row)                                                                                                                                                            |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)<br>-> row                Number of the row (zero-based).                                                                              |
| <b>Result</b>      | Returns the application-specific data stored for this row, if any.<br>Returns 0 if there is no application-specific data value.<br><br>This function may display a fatal error message if the row parameter is invalid. |
| <b>See Also</b>    | <a href="#">TblFindRowData</a> , <a href="#">TblSetRowData</a> , <a href="#">TableRowAttrType</a>                                                                                                                       |

## TblGetRowHeight

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the height of the specified row.                                           |
| <b>Declared In</b> | Table.h                                                                           |
| <b>Prototype</b>   | Coord TblGetRowHeight (const TableType *tableP,<br>Int16 row)                     |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .) |

## Tables

### Table Functions

---

-> row                      Number of the row (zero-based).

**Result**                      Returns the height in pixels. This function may display a fatal error message if the row parameter is invalid.

**See Also**                      [TblGetItemBounds](#), [TblSetRowHeight](#)

## TblGetRowID

**Purpose**                        Return the ID value of the specified row.

**Declared In**                  `Table.h`

**Prototype**                    `UInt16 TblGetRowID (const TableType *tableP,  
Int16 row)`

**Parameters**                  -> tableP                      Pointer to a table object. (See [TableType](#).)  
-> row                         Number of the row (zero-based).

**Result**                        Returns the ID value of the row in the table.  
This function may display a fatal error message if the row parameter is invalid.

**See Also**                      [TblGetRowData](#), [TblSetRowID](#), [TblFindRowID](#),  
[TableRowAttrType](#)

## TblGetSelection

**Purpose**                        Return the row and column of the currently selected table item.

**Declared In**                  `Table.h`

**Prototype**                    `Boolean TblGetSelection (const TableType *tableP,  
Int16 *rowP, Int16 *columnP)`

**Parameters**                  -> tableP                      Pointer to a table object. (See [TableType](#).)

`<- rowP, columnP`

The row and column indexes (zero-based) of the currently selected item.

**Result** Returns `true` if the item is highlighted, `false` if not.

**See Also** [TblSetRowSelectable](#)

## TblGetTopRow

**Purpose** Return the top row visible row of a table.

**Declared In** `Table.h`

**Prototype** `Int16 TblGetTopRow(const TableType *tableP)`

**Parameters** `-> tableP` Pointer to a [TableType](#).

**Result** This function returns the top visible row in a table.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TblGlueGetToRow`. For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

**See Also** [TblGetNumberOfColumns](#), [TblSetSelection](#)

## TblGrabFocus

**Purpose** Put a table into edit mode.

**Declared In** `Table.h`

**Prototype** `void TblGrabFocus (TableType *tableP, Int16 row, Int16 column)`

**Parameters** `-> tableP` Pointer to a table object. (See [TableType](#).)

## Tables

### Table Functions

---

-> row                    Current row to be edited (zero-based).  
-> column                Current column to be edited (zero-based).

**Result**      Returns nothing. This function may display a fatal error message if the table already has the focus or if the `row` or `column` parameter is invalid.

**Comments**    This function puts the table into edit mode and sets the current item to the one at the row and column passed in. An editable field must exist in the coordinates passed to this function.

You must call [FrmSetFocus](#) before calling this function. `FrmSetFocus` releases the focus from the object that previously had it and sets the form's internal structures. After calling this function, you must call [FldGrabFocus](#) to display the insertion point in the field. (You can use [TblGetCurrentField](#) to obtain a pointer to the field.)

For example, the following function from the Address Book application sets the focus in an editable field within a table:

```
static void EditViewRestoreEditState () {
    Int16      row;
    FormPtr    frm;
    TablePtr   table;
    FieldPtr   fld;

    if (CurrentFieldIndex == noFieldIndex)
        return;

    // Find the row that the current field is in.
    table = GetObjectPtr (EditTable);
    if ( ! TblFindRowID (table,
        CurrentFieldIndex, &row) )
        return;

    frm = FrmGetActiveForm ();
    FrmSetFocus (frm, FrmGetObjectIndex (frm,
        EditTable));
    TblGrabFocus (table, row, editDataColumn);
}
```

```
        // Restore the insertion point position.  
        fld = TblGetCurrentField (table);  
        FldSetInsPtPosition (fld, EditFieldPosition);  
        FldGrabFocus (fld);  
    }
```

**See Also** [TblReleaseFocus](#)

## TblHandleEvent

**Purpose** Handle an event for the table.

**Declared In** `Table.h`

**Prototype** `Boolean TblHandleEvent (TableType *tableP,  
EventTypes *event)`

**Parameters** `-> tableP` Pointer to a table object. (See [TableType](#).)  
`-> event` The event to be handled.

**Result** Returns `true` if the event was handled, `false` if it was not.

**Comments** Returns `false` if the table is not an editable table.

If the table is editable, this function passes along any [keyDownEvent](#), [fldEnterEvent](#), or [menuCmdBarOpenEvent](#) to the currently selected field.

When a [fldHeightChangedEvent](#) occurs, this function changes the height of the specified field as indicated by the event. If the field being resized is going to scroll off the bottom of the screen, then instead the table scrolls the rows above it up off the top. Otherwise, the table is scrolled downward and rows below the current row are scrolled off the bottom as necessary.

Note that the [fldHeightChangedEvent](#) is only handled for dynamically sized fields. See the descriptions of [FieldAttrType](#) and [FldMakeFullyVisible](#) for more information.

When a [penDownEvent](#) occurs, the table checks to see if the focus is being changed. If it is and the user was previously editing a text

## Tables

### Table Functions

---

field within the table, it saves the data in the table cell using the [TableSaveDataFuncType](#) callback function, then it enqueues a [tblEnterEvent](#) with the new row and column that are selected.

When a [tblEnterEvent](#) occurs, this function tracks the pen until it is lifted. If the pen is lifted within the bounds of the same item it went down in, a [tblSelectEvent](#) is added to the event queue; if not, a [tblExitEvent](#) is added to the event queue.

### TblHasScrollBar

|                      |                                                                                                                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Set the <code>hasScrollBar</code> attribute in the table. (See <a href="#">TableAttrType</a> .)                                                                                                                                                               |
| <b>Declared In</b>   | <code>Table.h</code>                                                                                                                                                                                                                                          |
| <b>Prototype</b>     | <code>void TblHasScrollBar (TableType *tableP,<br/>Boolean hasScrollBar)</code>                                                                                                                                                                               |
| <b>Parameters</b>    | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)<br><code>-&gt; hasScrollBar</code> <code>true</code> to set the attribute, <code>false</code> to unset it.                                                             |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                              |
| <b>Comments</b>      | Your application must scroll the table itself and keep track of the scroll values. See the <code>ListviewUpdateScrollers</code> function in the Memo example application ( <code>MemoMain.c</code> ) for an example of setting scroll bar values for a table. |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                                           |

## **TblInsertRow**

- Purpose** Insert a row into the table before the specified row.
- Declared In** `Table.h`
- Prototype** `void TblInsertRow (TableType *tableP, Int16 row)`
- Parameters**
- |           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> row    | Row to insert (zero-based).                                  |
- Result** Returns nothing.
- Comments**
- The number of rows in a table is the maximum number of rows displayed on the screen. Unlike a multi-line text field, there is no notion of a table that is bigger than the available screen. For this reason, this function does not increase the number of table rows.
- Instead of keeping track of a total number of rows in the table and a number of rows displayed on the screen, tables mark any row that isn't currently displayed with a usable value of `false`. (See [TableRowAttrType](#).)
- The newly inserted row is marked as invalid, unusable, and not masked. If you want to display the newly inserted row, call [TblSetRowUsable](#) after making sure that the row displays a value and then call [TblRedrawTable](#) when you are ready to draw the table.
- See Also** [TblRemoveRow](#), [TblSetRowUsable](#), [TblSetRowSelectable](#)

## Tables

### Table Functions

---

#### TblMarkRowInvalid

|                    |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Mark the row invalid.                                                                                                                                                                                         |
| <b>Declared In</b> | Table.h                                                                                                                                                                                                       |
| <b>Prototype</b>   | <pre>void TblMarkRowInvalid (TableType *tableP,<br/>Int16 row)</pre>                                                                                                                                          |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)<br>-> row                Row number (zero-based).                                                                           |
| <b>Result</b>      | Returns nothing.                                                                                                                                                                                              |
| <b>Comments</b>    | After calling this function, call <a href="#">TblRedrawTable</a> to redraw all rows marked invalid.<br><br>This function may display a fatal error message if the row parameter is invalid.                   |
| <b>See Also</b>    | <a href="#">TblRemoveRow</a> , <a href="#">TblSetRowUsable</a> , <a href="#">TblSetRowSelectable</a> , <a href="#">TblMarkTableInvalid</a> , <a href="#">TblRowInvalid</a> , <a href="#">TableRowAttrType</a> |

#### TblMarkTableInvalid

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Purpose</b>     | Mark all the rows in a table invalid.                                             |
| <b>Declared In</b> | Table.h                                                                           |
| <b>Prototype</b>   | <pre>void TblMarkTableInvalid (TableType *tableP)</pre>                           |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .) |
| <b>Result</b>      | Returns nothing.                                                                  |

**Comments** After calling this function, you must call [TblRedrawTable](#) to redraw all rows.

**See Also** [TblEraseTable](#), [TblRedrawTable](#), [TableRowAttrType](#)

## **TblRedrawTable**

**Purpose** Redraw the rows of the table that are marked invalid.

**Declared In** `Table.h`

**Prototype** `void TblRedrawTable (TableType *tableP)`

**Parameters** `-> tableP` Pointer to a table object. (See [TableType](#).)

**Result** Returns nothing.

**Comments** This function draws the invalid rows in the table. See the [TableItemType](#) struct description for more information about how each type of table cell is drawn.

When drawing cells with editable text fields (`textTableItem`, `textWithNoteTableItem`, or `narrowTextTableItem`), this function uses the [TableLoadDataFuncType](#) callback function to load the text into the table cells. The text field does not retain the text handle that your `TableLoadDataFunc` returns, meaning that you are responsible for freeing the memory that you load into the table.

When drawing `narrowTextTableItem` cells, `customTableItem` cells, or `tallCustomTableItem` cells, this function uses the [TableDrawItemFuncType](#) callback function to draw the extra pixels after the text or to draw the entire cell.

On color systems, tables are always drawn using the same color as is used for the field background color.

When the user has set the security setting to mask private records, table cells that contain private database records are drawn as shaded cells to obscure the information they contain. You must explicitly tell the table which cells are masked by making the

## Tables

### Table Functions

---

appropriate calls to [TblSetRowMasked](#) and [TblSetColumnMasked](#).

**Compatibility** Color support and masked private records are only supported in Palm OS version 3.5 and higher.

**See Also** [TblMarkTableInvalid](#), [TblMarkRowInvalid](#), [TblDrawTable](#)

## TblReleaseFocus

**Purpose** Release the focus.

**Declared In** `Table.h`

**Prototype** `void TblReleaseFocus (TableType *tableP)`

**Parameters** `-> tableP` Pointer to a table object.

**Result** Returns nothing.

**Comments** You typically do not call this function yourself. Instead, call [FrmSetFocus](#) with an object index of `noFocus` to notify the form that the table has lost focus. The form code calls `TblReleaseFocus` for you.

If the current item is a text item, the [TableSaveDataFuncType](#) callback function is called to save the text in the currently selected field, the memory allocated for editing is released, and the insertion point is turned off.

Also note that you might have to call [FldReleaseFocus](#) if the focus is in an editable text field and that field uses a custom drawing function ([TableDrawItemFuncType](#)).

**See Also** [TblGrabFocus](#)

## TblRemoveRow

|                    |                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Remove the specified row from the table.                                                                                                                                                                                                                                                                                    |
| <b>Declared In</b> | <code>Table.h</code>                                                                                                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <code>void TblRemoveRow (TableType *tableP, Int16 row)</code>                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)<br><code>-&gt; row</code> Row to remove (zero-based).                                                                                                                                                                                |
| <b>Result</b>      | Returns nothing. This function may raise a fatal error message if an invalid row is specified.                                                                                                                                                                                                                              |
| <b>Comments</b>    | The number of rows in the table is not decreased; instead, this row is moved from its current spot to the end of the table and is marked unusable so that it won't be displayed when the table is redrawn. This function does not visually update the display. To update the display, call <a href="#">TblRedrawTable</a> . |
| <b>See Also</b>    | <a href="#">TblInsertRow</a> , <a href="#">TblSetRowUsable</a> , <a href="#">TblSetRowSelectable</a> , <a href="#">TblMarkRowInvalid</a>                                                                                                                                                                                    |

## TblRowInvalid

|                    |                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return whether a row is invalid.                                                                                                                                  |
| <b>Declared In</b> | <code>Table.h</code>                                                                                                                                              |
| <b>Prototype</b>   | <code>Boolean TblRowInvalid (const TableType *tableP, Int16 row)</code>                                                                                           |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)<br><code>-&gt; row</code> Row number (zero-based).                         |
| <b>Result</b>      | Returns <code>true</code> if the row is invalid, <code>false</code> if it's valid. This function may raise a fatal error message if the row parameter is invalid. |

## Tables

### Table Functions

---

**Comments** Invalid rows need to be redrawn. Use [TblRedrawTable](#) to do so.

**See Also** [TblMarkRowInvalid](#), [TblMarkTableInvalid](#)

## TblRowMasked

**Purpose** Return whether a row is masked.

**Declared In** `Table.h`

**Prototype** `Boolean TblRowMasked (const TableType *tableP,  
Int16 row)`

**Parameters**

|           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> row    | Row number (zero-based).                                     |

**Result** Returns `true` if the row is masked, `false` otherwise.

**Comments** Your code should set a row to masked if it contains a private database record and the user has set the display preference for private records to masked. Masked cells are displayed as shaded.

Note that a table cell is not masked unless both its row and column are masked. This allows non-private information in the row item to remain visible. For example, the Datebook application shows the time for a private appointment, but it does not show the description.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [TblSetRowMasked](#), [TblSetColumnMasked](#),  
[TableRowAttrType](#), [SecSelectViewStatus](#)

## TblRowSelectable

|                    |                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return whether the specified row is selectable.                                                                                           |
| <b>Declared In</b> | <code>Table.h</code>                                                                                                                      |
| <b>Prototype</b>   | <code>Boolean TblRowSelectable<br/>(const TableType *tableP, Int16 row)</code>                                                            |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)<br><code>-&gt; row</code> Row number (zero-based). |
| <b>Result</b>      | Returns <code>true</code> if the row is selectable, <code>false</code> if it's not.                                                       |
| <b>Comments</b>    | Rows that are not selectable don't highlight when touched.                                                                                |
| <b>See Also</b>    | <a href="#">TableRowAttrType</a>                                                                                                          |

## TblRowUsable

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Determine whether the specified row is usable.                                                                                                                          |
| <b>Declared In</b> | <code>Table.h</code>                                                                                                                                                    |
| <b>Prototype</b>   | <code>Boolean TblRowUsable (const TableType *tableP,<br/>Int16 row)</code>                                                                                              |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)<br><code>-&gt; row</code> Row number (zero-based).                               |
| <b>Result</b>      | Returns <code>true</code> if the row is usable, <code>false</code> if it's not.<br><br>This function may display a fatal error message if the row parameter is invalid. |

## Tables

### Table Functions

---

**Comments** Rows that are not usable do not display.

**See Also** [TblRowSelectable](#), [TblGetLastUsableRow](#),  
[TblSetRowUsable](#)

## TblSelectItem

**Purpose** Select (highlight) the specified item. If there is already a selected item, it is unhighlighted.

**Declared In** `Table.h`

**Prototype** `void TblSelectItem (TableType *tableP, Int16 row,  
Int16 column)`

**Parameters**

|           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> row    | Row of the item to select (zero-based).                      |
| -> column | Column of the item to select (zero-based).                   |

**Result** Returns nothing.

This function may display a fatal error message if the `column` or `row` parameter point to an item that is not on the screen.

**Comments** If `row` contains a masked private database record, then the item remains unselected.

This function cannot highlight an entire row; it can only highlight one cell in a row, and it always unhighlights the previously selected table cell. If you want to select an entire row, either create a table that has a single column, or write your own selection code.

If the selected item is a multi-line text field or a text field with a nonstandard height, this function only highlights the top eleven pixels. If you want a larger area highlighted, you must write your own selection code.

**See Also** [TblRowSelectable](#), [TblGetItemBounds](#), [TblGetItemInt](#)

## **TblSetBounds**

|                      |                                                                     |                                                                               |
|----------------------|---------------------------------------------------------------------|-------------------------------------------------------------------------------|
| <b>Purpose</b>       | Sets the bounds of a table.                                         |                                                                               |
| <b>Declared In</b>   | Table.h                                                             |                                                                               |
| <b>Prototype</b>     | void TblSetBounds (TableType *tableP,<br>const RectangleType *rP)   |                                                                               |
| <b>Parameters</b>    | -> tableP                                                           | Pointer to a table object. (See <a href="#">TableType</a> .)                  |
|                      | -> rP                                                               | Pointer to a RectangleType structure that specifies the bounds for the table. |
| <b>Result</b>        | Returns nothing.                                                    |                                                                               |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present. |                                                                               |

## **TblSetColumnEditIndicator**

|                    |                                                                                                                                      |                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <b>Purpose</b>     | Set the column attribute that controls whether a column highlights when the table is in edit mode.                                   |                                                              |
| <b>Declared In</b> | Table.h                                                                                                                              |                                                              |
| <b>Prototype</b>   | void TblSetColumnEditIndicator<br>(TableType *tableP, Int16 column,<br>Boolean editIndicator)                                        |                                                              |
| <b>Parameters</b>  | -> tableP                                                                                                                            | Pointer to a table object. (See <a href="#">TableType</a> .) |
|                    | -> column                                                                                                                            | Column number (zero based).                                  |
|                    | -> editIndicator                                                                                                                     | true to highlight, false to turn off highlight.              |
| <b>Result</b>      | Returns nothing.                                                                                                                     |                                                              |
| <b>Comments</b>    | The edit indicator controls whether the item in the column is highlighted when it is selected. By default, text field items have the |                                                              |

## Tables

### Table Functions

---

editIndicator value of `false`, while all other table item types have an edit indicator of `true`.

When the table is drawn, only the leftmost contiguous set of items with the edit indicator set are drawn as highlighted. That is, if columns 1, 2, and 4 have an edit indicator of `true` and column 3 has an edit indicator of `false`, only the items in column 1 and 2 are drawn as highlighted when selected. Column 4 items are not drawn as highlighted.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [TableColumnAttrType](#)

## TblSetColumnMasked

**Purpose** Set whether the column is masked.

**Declared In** `Table.h`

**Prototype** `void TblSetColumnMasked (TableType *tableP,  
Int16 column, Boolean masked)`

**Parameters**

|           |                                                                               |
|-----------|-------------------------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .)                  |
| -> column | Column number (zero-based).                                                   |
| -> masked | <code>true</code> to have the column be masked, <code>false</code> otherwise. |

**Result** Returns nothing.

**Comments** Masked cells are displayed as shaded. You should set a column to masked if its contents should be hidden when it contains information from a private database record and the user has set the display preference for private records to masked.

A table cell is not masked unless both its row and column are masked. This allows non-private information in the row item to remain visible. For example, the Datebook application shows the time for a private appointment, but it does not show the description.

Because the number of columns is static, you only need to call this function once per column when you first set up the table. The masked attribute on the row will determine if the contents of the table cell are actually displayed as shaded.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [TblRowMasked](#), [TblSetRowMasked](#), [TableColumnAttrType](#), [SecSelectViewStatus](#)

## **TblSetColumnSpacing**

**Purpose** Set the spacing after the specified column.

**Declared In** `Table.h`

**Prototype** `void TblSetColumnSpacing (TableType *tableP,  
Int16 column, Coord spacing)`

**Parameters**

|            |                                                              |
|------------|--------------------------------------------------------------|
| -> tableP  | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> column  | Column number (zero-based).                                  |
| -> spacing | Spacing after the column in pixels.                          |

**Result** Returns nothing.

This function may display a fatal error message if the `column` parameter is invalid.

**See Also** [TblSetColumnUsable](#), [TableColumnAttrType](#)

## Tables

### Table Functions

---

#### TblSetColumnUsable

- Purpose** Set a column in a table to usable or unusable.
- Declared In** `Table.h`
- Prototype**  
`void TblSetColumnUsable (TableType *tableP,  
Int16 column, Boolean usable)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `column` Column number (zero-based).
  - > `usable` `true` for usable or `false` for not usable.
- Result** Returns nothing.  
This function may display a fatal error message if the `column` parameter is invalid.
- Comments** Columns that are not usable do not display.
- See Also** [TblMarkRowInvalid](#), [TableColumnAttrType](#)

#### TblSetColumnWidth

- Purpose** Set the width of the specified column.
- Declared In** `Table.h`
- Prototype**  
`void TblSetColumnWidth (TableType *tableP,  
Int16 column, Coord width)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `column` Column number (zero-based).
  - > `width` Width of the column (in pixels).
- Result** Returns nothing.

This function may display a fatal error message if the `column` parameter is invalid.

**See Also** [TblGetColumnWidth](#), [TableColumnAttrType](#)

## **TblSetCustomDrawProcedure**

**Purpose** Set the custom draw callback procedure for the specified column.

**Declared In** `Table.h`

**Prototype**

```
void TblSetCustomDrawProcedure
(TableType *tableP, Int16 column,
TableDrawItemFuncPtr drawCallback)
```

**Parameters**

- > `tableP` Pointer to a table object. (See [TableType](#).)
- > `column` Column number.
- > `drawCallback` Callback function.

**Result** Returns nothing.

**Comments** The custom draw callback function is used to draw table items with a `TableItemStyleType` of `customTableItem` or `tblCustomTableItem`. See the [TableItemType](#) description for more information.

This function may display a fatal error message if the `column` parameter is invalid.

**See Also** [TableDrawItemFuncType](#), [TblDrawTable](#), [TableColumnAttrType](#)

## Tables

### Table Functions

---

## TblSetItemFont

- Purpose** Set the font used to display a table item.
- Declared In** `Table.h`
- Prototype**  
`void TblSetItemFont (TableType *tableP,  
Int16 row, Int16 column, FontID fontID)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `row` Row number of the item (zero-based).
  - > `column` Column number of the item (zero-based).
  - > `fontID` ID of the font to be used.
- Result** Returns nothing.
- Comments** This function sets the value stored in the `fontID` field for this table item. Only certain types of table items use the font specified by the `fontID` field when they are displayed. The [TableItemType](#) description specifies what font is used to display each type of table item. It is not an error to set the `fontID` for a table item that does not use it.
- This function may display a fatal error message if the `row` or `column` parameter specifies a row or column that is not on the screen.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.
- See Also** [TblGetItemFont](#)

## TblSetItemInt

- Purpose** Set the integer value of the specified item.
- Declared In** `Table.h`
- Prototype** `void TblSetItemInt (TableType *tableP, Int16 row, Int16 column, Int16 value)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `row` Row number of the item (zero-based).
  - > `column` Column number of the item (zero-based).
  - > `value` Any byte value (an integer).
- Result** Returns nothing.
- This function may display a fatal error message if the `row` or `column` parameter is invalid.
- Comments** You typically use this function when setting up and initializing a table for the first time to set the value of each table cell.
- This function sets the value stored in the `intValue` field for this table item. Certain types of table items display the value stored in `intValue`, and other types display the value pointed to by the `ptr` field. See the [TableItemType](#) description for details. If you set the `intValue` of an item that displays its `ptr` value, it is not an error. An application can store whatever value it wants in the `intValue` field; however, be aware that this has nothing to do with the value displayed by such a table cell.
- See Also** [TblGetItemInt](#), [TblSetItemPtr](#)

## Tables

### Table Functions

---

## TblSetItemPtr

- Purpose** Set the item to the specified pointer value.
- Declared In** `Table.h`
- Prototype**  
`void TblSetItemPtr (TableType *tableP, Int16 row, Int16 column, void *value)`
- Parameters**
- |                        |                                                              |
|------------------------|--------------------------------------------------------------|
| -> <code>tableP</code> | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> <code>row</code>    | Row number of the item (zero-based).                         |
| -> <code>column</code> | Column number of the item (zero-based).                      |
| -> <code>value</code>  | Pointer to data to display in the table item.                |
- Result** Returns nothing.  
This function may display a fatal error message if the `row` or `column` parameter is invalid.
- Comments** This function sets the value stored in the `ptr` field for this table item. Certain types of table items display the value pointed to by `ptr`, and other types display the value stored in the `intValue` field. See the [TableItemType](#) description for details. If you set the `ptr` of an item that displays its `intValue`, it is not an error. An application can store whatever value it wants in the `ptr` field; however, be aware that this has nothing to do with the value displayed by such a table cell.
- See Also** [TblGetItemPtr](#), [TblSetItemInt](#)

## **TblSetItemStyle**

**Purpose** Set the type of item to display; for example, text, numbers, dates, and so on.

**Declared In** `Table.h`

**Prototype** `void TblSetItemStyle (TableType *tableP,  
Int16 row, Int16 column, TableItemStyleType type)`

## Tables

### Table Functions

---

|                   |           |                                                                                                                                   |
|-------------------|-----------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .)                                                                      |
|                   | -> row    | Row number of the item (zero-based).                                                                                              |
|                   | -> column | Column number of the item (zero-based).                                                                                           |
|                   | -> type   | The type of item, such as an editable text field or a check box. See <a href="#">TableItemType</a> for a list of possible values. |

**Result** Returns nothing.

This function may display a fatal error message if the row or column parameter is invalid.

**Comments** You typically use this function when first setting up and initializing a table; you do not dynamically change item styles.

Follow this function with a call to either [TblSetItemInt](#) or [TblSetItemPtr](#) to set the value displayed by the table item. You should call one or the other of these functions depending on the type of table item you specified. See the table in the [TableItemType](#) description for details.

Note also that a table column always contains items of the same type. For example, you might initialize a table using this code:

```
for (row = 0; row < rowsInTable; row++) {
    TblSetItemStyle (table, row, completedColumn,
                    checkboxTableItem);
    TblSetItemStyle (table, row, priorityColumn,
                    numericTableItem);
    TblSetItemStyle (table, row, descColumn,
                    textTableItem);
    TblSetItemStyle (table, row, dueDateColumn,
                    customTableItem);
    TblSetItemStyle (table, row, categoryColumn,
                    customTableItem);
}
```

**See Also** [TblSetCustomDrawProcedure](#)

## **TblSetLoadDataProcedure**

- Purpose** Set the load-data callback procedure for the specified column.
- Declared In** `Table.h`
- Prototype**  
`void TblSetLoadDataProcedure (TableType *tableP,  
Int16 column,  
TableLoadDataFuncPtr loadDataCallback)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)
  - > `column` Column number (zero-based).
  - > `loadDataCallback` Callback procedure. See [TableLoadDataFuncType](#).
- Result** Returns nothing.
- Comments** The callback procedure is used to load the data values of a table item. See the [TableLoadDataFuncType](#) for more information on writing the callback function.
- You typically use this function when first setting up and initializing a table.
- See Also** [TblSetCustomDrawProcedure](#)

## **TblSetRowData**

- Purpose** Set the data value of the specified row. The data value is a placeholder for application-specific values.
- Declared In** `Table.h`
- Prototype**  
`void TblSetRowData (TableType *tableP, Int16 row,  
UInt32 data)`
- Parameters**
- > `tableP` Pointer to a table object. (See [TableType](#).)

## Tables

### Table Functions

---

-> row            Row number (zero-based).  
-> data            Application-specific data value to store for this row. For example, the Datebook and ToDo applications use this field to store the unique ID of the database record displayed by this row.

**Result**        Returns nothing.

This function may display a fatal error message if the row parameter is invalid.

**See Also**      [TblGetRowData](#), [TblFindRowData](#)

## TblSetRowHeight

**Purpose**        Set the height of the specified row.

**Declared In**   `Table.h`

**Prototype**     `void TblSetRowHeight (TableType *tableP,  
                         Int16 row, Coord height)`

**Parameters**    -> tableP        Pointer to a table object. (See [TableType](#).)  
                  -> row            Row number (zero-based).  
                  -> height        New height in pixels.

**Result**        Returns nothing.

This function may display a fatal error message if the row parameter is invalid.

**See Also**      [TblGetRowHeight](#), [TblSetRowStaticHeight](#)

## **TblSetRowID**

**Purpose** Set the ID value of the specified row.

**Declared In** `Table.h`

**Prototype** `void TblSetRowID (TableType *tableP, Int16 row, UInt16 id)`

## Tables

### Table Functions

---

**Parameters**

|           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> row    | Row number (zero-based).                                     |
| -> id     | ID to identify a row.                                        |

**Result** Returns nothing.  
This function may display a fatal error message if the row parameter is invalid.

**See Also** [TblGetRowID](#), [TblFindRowID](#), [TableRowAttrType](#)

## TblSetRowMasked

**Purpose** Set a row in a table to masked or unmasked.

**Declared In** `Table.h`

**Prototype** `void TblSetRowMasked (TableType *tableP,  
Int16 row, Boolean masked)`

**Parameters**

|           |                                                              |
|-----------|--------------------------------------------------------------|
| -> tableP | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> row    | Row number (zero-based).                                     |
| -> masked | true to have the row be masked, false otherwise.             |

**Result** Returns nothing.

**Comments** Masked cells are displayed as shaded. You should call this function before drawing or redrawing the table. If a table row contains a private database record and the user has set the display preference for private records to masked, you must call this function on that row. For example:

```
UInt16 attr;  
privateRecordViewEnum privateRecordStatus;  
Boolean masked;  
  
privateRecordStatus = (privateRecordViewEnum)
```

```
    PrefGetPreference(prefShowPrivateRecords);  
    ....  
    DmRecordInfo (ToDoDB, recordNum, &attr, NULL,  
        NULL);  
    masked = ((attr & dmRecAttrSecret) &&  
        (privateRecordStatus == maskPrivateRecords));  
    TblSetRowMasked(tableP, row, masked);
```

Note that a table cell is not masked unless both its row and column are masked. This allows non-private information in the row item to remain visible. For example, the Datebook application shows the time for a private appointment, but it does not show the description.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [TblRowMasked](#), [TblSetColumnMasked](#), [TableRowAttrType](#), [SecSelectViewStatus](#)

## TblSetRowSelectable

**Purpose** Set a row in a table to selectable or nonselectable.

**Declared In** `Table.h`

**Prototype** `void TblSetRowSelectable (TableType *tableP,  
 Int16 row, Boolean selectable)`

**Parameters**

|               |                                                              |
|---------------|--------------------------------------------------------------|
| -> tableP     | Pointer to a table object. (See <a href="#">TableType</a> .) |
| -> row        | Row number (zero-based).                                     |
| -> selectable | true or false.                                               |

**Result** Returns nothing.

This function may display a fatal error message if the row parameter is invalid.

**Comments** Rows that are not selectable don't highlight when touched.

**See Also** [TblRowSelectable](#), [TblSetRowUsable](#), [TableRowAttrType](#)

## Tables

### Table Functions

---

#### TblSetRowStaticHeight

|                      |                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Set the static height attribute of a row.                                                                                                                                                                   |
| <b>Declared In</b>   | Table.h                                                                                                                                                                                                     |
| <b>Prototype</b>     | <pre>void TblSetRowStaticHeight (TableType *tableP,<br/>Int16 row, Boolean staticHeight)</pre>                                                                                                              |
| <b>Parameters</b>    | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)<br>-> row                Row number (zero-based).<br>-> staticHeight    true to set the static height, false to unset it. |
| <b>Result</b>        | Nothing.<br><br>This function may display a fatal error message if the row parameter is invalid.                                                                                                            |
| <b>Comments</b>      | A row that has its static height attribute set will not expand or contract the height of the row as text is added or removed from a text item.                                                              |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                         |

#### TblSetRowUsable

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Set a row in a table to usable or unusable. Rows that are not usable do not display.                                                |
| <b>Declared In</b> | Table.h                                                                                                                             |
| <b>Prototype</b>   | <pre>void TblSetRowUsable (TableType *tableP,<br/>Int16 row, Boolean usable)</pre>                                                  |
| <b>Parameters</b>  | -> tableP            Pointer to a table object. (See <a href="#">TableType</a> .)<br>-> row                Row number (zero-based). |

-> usable            true or false.

**Result**      Returns nothing.

This function may display a fatal error message if the row parameter is invalid.

**See Also**    [TblRowUsable](#), [TblSetRowSelectable](#)

## **TblSetSaveDataProcedure**

**Purpose**      Set the save-data callback procedure for the specified column.

**Declared In**    `Table.h`

**Prototype**    `void TblSetSaveDataProcedure (TableType *tableP,  
                                  Int16 column,  
                                  TableSaveDataFuncPtr saveDataCallback)`

**Parameters**    -> tableP            Pointer to a table object. (See [TableType](#).)  
                  -> column            Column number (zero-based).  
                  -> saveDataCallback    Callback function. See [TableSaveDataFuncType](#).

**Result**      Returns nothing.

This function may display a fatal error message if the column parameter is invalid.

**Comments**    The callback procedure is called when the table object determines the data of a text object needs to be saved.

**See Also**    [TblSetCustomDrawProcedure](#)

## Tables

### Table Functions

---

## TblSetSelection

|                      |                                                                                                                                                                                                                                                                                                                                 |           |                                          |        |            |           |               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|------------------------------------------|--------|------------|-----------|---------------|
| <b>Purpose</b>       | Set a table item.                                                                                                                                                                                                                                                                                                               |           |                                          |        |            |           |               |
| <b>Declared In</b>   | Table.h                                                                                                                                                                                                                                                                                                                         |           |                                          |        |            |           |               |
| <b>Prototype</b>     | <pre>void TblSetSelection (TableType *tableP,<br/>Int16 row, Int16 column)</pre>                                                                                                                                                                                                                                                |           |                                          |        |            |           |               |
| <b>Parameters</b>    | <table><tr><td>-&gt; tableP</td><td>Pointer to a <a href="#">TableType</a>.</td></tr><tr><td>-&gt; row</td><td>Table row.</td></tr><tr><td>-&gt; column</td><td>Table column.</td></tr></table>                                                                                                                                 | -> tableP | Pointer to a <a href="#">TableType</a> . | -> row | Table row. | -> column | Table column. |
| -> tableP            | Pointer to a <a href="#">TableType</a> .                                                                                                                                                                                                                                                                                        |           |                                          |        |            |           |               |
| -> row               | Table row.                                                                                                                                                                                                                                                                                                                      |           |                                          |        |            |           |               |
| -> column            | Table column.                                                                                                                                                                                                                                                                                                                   |           |                                          |        |            |           |               |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                |           |                                          |        |            |           |               |
| <b>Comments</b>      | This function sets a table item, determined by the row and column arguments, as the current selection. <a href="#">TblDrawTable</a> must be called afterwards to update the UI.                                                                                                                                                 |           |                                          |        |            |           |               |
| <b>Compatibility</b> | Implemented only if <a href="#">4.0 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TblGlueSetSelection</code> . For more information, see <a href="#">Chapter 75</a> , " <a href="#">PalmOSGlue Library</a> ." |           |                                          |        |            |           |               |
| <b>See Also</b>      | <a href="#">TblGetNumberOfColumns</a> , <a href="#">TblGetTopRow</a>                                                                                                                                                                                                                                                            |           |                                          |        |            |           |               |

## TblUnhighlightSelection

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Unhighlight the currently selected item in a table.                                    |
| <b>Declared In</b> | <code>Table.h</code>                                                                   |
| <b>Prototype</b>   | <code>void TblUnhighlightSelection (TableType *tableP)</code>                          |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .) |
| <b>Result</b>      | Returns nothing.                                                                       |

## Application-Defined Functions

### TableDrawItemFuncType

|                    |                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Draw a custom table item.                                                                                                                                                                                                                                                                                                                |
| <b>Declared In</b> | <code>Table.h</code>                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <code>void TableDrawItemFuncType (void *tableP,<br/>Int16 row, Int16 column, RectangleType *bounds)</code>                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <code>-&gt; tableP</code> Pointer to a table object. (See <a href="#">TableType</a> .)<br><code>-&gt; row</code> Row number of the item to be drawn (zero-based).<br><code>-&gt; column</code> Column number of the item to be drawn (zero-based).<br><code>-&gt; bounds</code> The area of the screen in which the item is to be drawn. |
| <b>Result</b>      | Returns nothing.                                                                                                                                                                                                                                                                                                                         |
| <b>Comments</b>    | This function is called during <a href="#">TblDrawTable</a> and <a href="#">TblRedrawTable</a> .                                                                                                                                                                                                                                         |

## Tables

### Application-Defined Functions

---

You implement a custom drawing function when your table contains items of type `customTableItem` or `tallCustomTableItem` (to draw the entire item) or `narrowTextTableItem` (to draw whatever is required in the space between the text and the right edge of the table cell).

You may implement a custom drawing function to include any style of information in the table. If you don't like the way a predefined item is drawn, you may prefer to use a `customTableItem` or `tallCustomTableItem` instead. For example, if you want to include a date in your table but you want it to show the year as well as the month and day, you should implement a custom drawing function.

**See Also** [TblSetCustomDrawProcedure](#), [TableItemType](#)

## TableLoadDataFuncType

**Purpose** Load data into a column.

**Declared In** `Table.h`

**Prototype** `Err TableLoadDataFuncType (void *tableP, Int16 row, Int16 column, Boolean editable, MemHandle *dataH, Int16 *dataOffset, Int16 *dataSize, FieldPtr fld)`

**Parameters**

|               |                                                                                                                                                |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| -> tableP     | Pointer to a table object. (See <a href="#">TableType</a> .)                                                                                   |
| -> row        | Row number of the table item to load.                                                                                                          |
| -> column     | Column number of the table item to load.                                                                                                       |
| -> editable   | If <code>true</code> , the table is currently being edited. If <code>false</code> , the table is being drawn but not necessarily being edited. |
| <- dataH      | Unlocked handle of a block containing a null-terminated text string.                                                                           |
| <- dataOffset | Offset from start of block to start of the text string.                                                                                        |

<- dataSize      Allocated size of text string, **not** the string length.  
 -> fld            Pointer to the text field in this table cell.

**Result**      Returns 0 upon success or an error if unsuccessful.

**Comments**    This function is called in two cases: when a text field item is being drawn ([TblDrawTable](#) or [TblRedrawTable](#)) and when a text field item is being selected (part of [TblHandleEvent](#)'s handling of [tblEnterEvent](#)). If this function returns an error (any nonzero value) and the item is being selected, then the item is not selected and the table's editing attribute is set to false.

You return the same values for dataH, dataOffset, and dataSize that you would pass to [FldSetText](#). That is, you can use this function to point the table cell's text field to a string in a database record so that you can edit that string directly using text field routines. To do so, return the handle to a database record in dataH, the offset from the start of the record to the start of the string in dataOffset, and the allocated size of the string in dataSize.

The handle that you return from this function is assumed to contain a null-terminated string starting at dataOffset bytes in the memory chunk. The string should be between 0 and dataSize - 1 bytes in length.

As with [FldSetText](#), you are responsible for freeing the memory associated with the dataH parameter. You can do so in the [TableSaveDataFuncType](#) function, but it is only called for a cell that has been edited. For non-editable text cells or text cells that are editable but were never selected, free the memory when you close the form.

The fld pointer passed to your function has already been initialized with default values by the table code. If you want to override a field's attributes (for example, if you want to change the underline mode) you can do so in this function.

(See <a href="#">TableType</a> .) | -> <code>row</code> | Row number of the table item to load. | -> <code>column</code> | Column number of the table item to load. |
| -> <code>tableP</code> | Pointer to a table object. (See <a href="#">TableType</a> .)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                        |                                                              |                     |                                       |                        |                                          |
| -> <code>row</code>    | Row number of the table item to load.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                        |                                                              |                     |                                       |                        |                                          |
| -> <code>column</code> | Column number of the table item to load.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |                                                              |                     |                                       |                        |                                          |
| <b>Result</b>          | Return <code>true</code> if the table should be redrawn, or <code>false</code> if the table does not need to be redrawn.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                        |                                                              |                     |                                       |                        |                                          |
| <b>Comments</b>        | <p>This is called before the memory associated with the currently selected text field in a table cell is freed. Implement this function if you need to do any special cleanup before this memory is freed.</p> <p>This function is called only when the currently selected editable text field is releasing the focus. You can use <a href="#">TblGetCurrentField</a> to retrieve a pointer to this field. It is called only on the currently selected field, not on any other fields in the table.</p> <p>Note that the table manager already disassociates the memory handle from the text field for you so that the memory associated with your data is not freed when the field is freed. The table manager also calls <a href="#">FldCompactText</a> for you.</p> <p>If the text handle you returned in your <a href="#">TableLoadDataFuncType</a> callback points to a string on the dynamic heap, you should implement this callback function to store or free the handle. You can use <a href="#">FldGetTextHandle</a> to obtain the handle.</p> <p>If you return <code>true</code> from this function, <a href="#">TblRedrawTable</a> is called. You should mark invalid any table rows that you want redrawn before returning.</p> |                        |                                                              |                     |                                       |                        |                                          |

# UI Color List

---

This chapter provides information about the UI color list by discussing the following topics:

- [UI Color Data Types](#)
- [UI Color Functions](#)

The header file `UIColor.h` declares the API that this chapter describes. For more information on the color list, see “[Color and Grayscale Support](#)” on page 144 in the *Palm OS Programmer’s Companion*, vol. I.

## UI Color Data Types

### UIColorTableEntries

The `UIColorTableEntries` enum declares symbolic color constants for the various UI elements.

Do not confuse the UI color list with the system color table. The **system color table** (or **system palette**) defines all available colors for the display or draw window, whether they are in use or not. The **UI color list** defines the colors used to draw the interface objects.

```
typedef enum UIColorTableEntries {
    UIObjectFrame = 0,
    UIObjectFill,
    UIObjectForeground,
    UIObjectSelectedFill,
    UIObjectSelectedForeground,

    UIMenuFrame,
    UIMenuFill,
    UIMenuForeground,
    UIMenuSelectedFill,
    UIMenuSelectedForeground,
```

## UI Color List

*UI Color Data Types*

```
UIFieldBackground,  
UIFieldText,  
UIFieldTextLines,  
UIFieldCaret,  
UIFieldTextHighlightBackground,  
UIFieldTextHighlightForeground,  
UIFieldFepRawText,  
UIFieldFepRawBackground,  
UIFieldFepConvertedText,  
UIFieldFepConvertedBackground,  
UIFieldFepUnderline,  
  
UIFormFrame,  
UIFormFill,  
  
UIDialogFrame,  
UIDialogFill,  
  
UIAlertFrame,  
UIAlertFill,  
  
UIOK,  
UICaution,  
UIWarning,  
  
UILastColorTableEntry  
} UIColorTableEntries;
```

### Field Descriptions

|                                |                                                                                                                                                                        |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UIObjectFrame                  | Color for the border of user interface objects (such as command buttons, push buttons, selector triggers, menus, arrows checkboxes, and other controls).               |
| UIObjectFill                   | The background color for a solid or “filled” user interface object.<br><br>Note that UI objects in tables use the UIField... colors instead of the UIObject... colors. |
| UIObjectForeground             | The color for foreground items (such as labels or graphics) in a user interface object.                                                                                |
| UIObjectSelectedFill           | The background color of the currently selected user interface object, whether that object is solid or not.                                                             |
| UIObjectSelectedForeground     | The color of foreground items in a selected user interface object.                                                                                                     |
| UIMenuFrame                    | The color of the border around the menu.                                                                                                                               |
| UIMenuFill                     | The background color of a menu item.                                                                                                                                   |
| UIMenuForeground               | The color of the menu’s text.                                                                                                                                          |
| UIMenuSelectedFill             | The background color of a selected menu item.                                                                                                                          |
| UIMenuSelectedForeground       | The color of the text of a selected menu item.                                                                                                                         |
| UIFieldBackground              | The background color of an editable text field.                                                                                                                        |
| UIFieldText                    | The color of the text in the editable field.                                                                                                                           |
| UIFieldTextLines               | The color of underlines in an editable field.                                                                                                                          |
| UIFieldCaret                   | The color of the cursor in an editable text field.                                                                                                                     |
| UIFieldTextHighlightBackground | The background color for selected text in an editable text field.                                                                                                      |

## UI Color List

### UI Color Data Types

---

|                                             |                                                                                                                                                                                                                                                |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>UIFieldTextHighlightForeground</code> | The color of the selected text in an editable text field.                                                                                                                                                                                      |
| <code>UIFieldFepRawText</code>              | Color used for unconverted text in the inline conversion area when a FEP is used as a text input method (for example, on Japanese devices).<br><br>If the FEP colors are identical to field colors, unconverted text has a solid underline.    |
| <code>UIFieldFepRawBackground</code>        | The background color for unconverted text in the inline conversion area when a FEP is used as a text input method.<br><br>If the FEP colors are identical to field colors, unconverted text has a solid underline.                             |
| <code>UIFieldFepConvertedText</code>        | Color used for converted text in the inline conversion area when a FEP is used as a text input method (for example, on Japanese devices).<br><br>If the FEP colors are identical to field colors, converted text has a double-thick underline. |
| <code>UIFieldFepConvertedBackground</code>  | The background color used for converted text in the inline conversion area.<br><br>If the FEP colors are identical to field colors, converted text has a double-thick underline.                                                               |
| <code>UIFieldFepUnderline</code>            | The color used for underlines in the inline conversion area.                                                                                                                                                                                   |
| <code>UIFormFrame</code>                    | The color of the border and titlebar on a form.                                                                                                                                                                                                |
| <code>UIFormFill</code>                     | The background color of a form. White is recommended for this value.                                                                                                                                                                           |
| <code>UIDialogFrame</code>                  | The color of a border and titlebar on a modal form.                                                                                                                                                                                            |

|                                    |                                                                                                                        |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>UIDialogFill</code>          | The background color of a modal form.                                                                                  |
| <code>UIAlertFrame</code>          | The color of the border and titlebar on an alert panel.                                                                |
| <code>UIAlertFill</code>           | The background color of an alert panel.                                                                                |
| <code>UIOK</code>                  | The color for an informational icon.                                                                                   |
| <code>UICaution</code>             | The color for a caution icon.                                                                                          |
| <code>UIWarning</code>             | The color for a warning icon.                                                                                          |
|                                    | Palm OS® does not currently use the <code>UIOK</code> , <code>UICaution</code> , and <code>UIWarning</code> constants. |
| <code>UILastColorTableEntry</code> | Placeholder to indicate end of enum.                                                                                   |

**Compatibility**    Implemented only if [3.5 New Feature Set](#) is present.

## UI Color Functions

### **UIColorGetTableEntryIndex**

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the index value for a UI color for the current system palette.                                                |
| <b>Declared In</b> | <code>UIColor.h</code>                                                                                               |
| <b>Prototype</b>   | <code>IndexedColorType UIColorGetTableEntryIndex (UIColorTableEntries which)</code>                                  |
| <b>Parameters</b>  | -> <code>which</code> One of the symbolic color constants. See <a href="#">UIColorTableEntries</a> .                 |
| <b>Result</b>      | Returns the system color table index of the color used for the specified symbolic color.                             |
| <b>Comments</b>    | One way to find out the indexes of all the colors that the OS is using is to loop through the UI color list, calling |

## **UI Color List**

*UI Color Functions*

---

UIColorGetTableEntryIndex for each slot, and keep a list (excluding duplicates).

```
IndexedColorType
    colorsUsed[UILastColorTableEntry];
UInt16 numColors = 0;
...
for (i = 0; i < UILastColorTableEntry; i++) {
    IndexedColorType currentColor;
    Boolean isNew = true;

    currentColor = UIColorGetTableEntryIndex(i);

    for (j = 0; ((j < numColors) && isNew); j++)
        if (colorsUsed[j] == currentColor)
            isNew = false; /* exit loop */
    if (isNew) {
        numColors++;
        colorsUsed[j] = currentColor;
    }
}
```

To get the RGB values of the colors, do the same thing but call [UIColorGetTableEntryRGB](#).

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [IndexedColorType](#), [WinIndexToRGB](#)

## **UIColorGetTableEntryRGB**

**Purpose** Return the RGB value for the UI color.

**Declared In** `UIColor.h`

**Prototype** `void UIColorGetTableEntryRGB  
(UIColorTableEntries which, RGBColorType *rgbP)`

**Parameters**

|          |                                                                                                                                    |
|----------|------------------------------------------------------------------------------------------------------------------------------------|
| -> which | One of the symbolic color constants. See <a href="#">UIColorTableEntries</a> .                                                     |
| <- rgbP  | Pointer to an RGB color value corresponding to the current color used for the symbolic color. (See <a href="#">RGBColorType</a> .) |

## **UI Color List**

*UI Color Functions*

---

- Result** Returns nothing.
- Comments** In general, it is more efficient to work with indexed color entries instead of RGB color entries.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [UIColorGetTableEntryIndex](#), [WinRGBToIndex](#)

## UIColorSetTableEntry

- Purpose** Change a value in the UI color list.
- Declared In** `UIColor.h`
- Prototype**  
`Err UIColorSetTableEntry  
(UIColorTableEntries which,  
const RGBColorType *rgbP)`
- Parameters**
- |          |                                                                                                                  |
|----------|------------------------------------------------------------------------------------------------------------------|
| -> which | One of the symbolic color constants. See <a href="#">UIColorTableEntries</a> .                                   |
| -> rgbP  | The RGB value of the color that should be used for the specified UI object. (See <a href="#">RGBColorType</a> .) |
- Result** Returns 0 upon success.
- Comments** Sets the value of a UI color entry to the passed RGB value. Updates the index for that UI color entry to the current best fit for that RGB value according to the palette used by the current draw window.
- It is best to use this function only if the draw window is currently onscreen. Otherwise, the best-fit algorithm may choose a color that is not available on the current screen.
- See Also** [WinIndexToRGB](#), [UIColorGetTableEntryIndex](#), [UIColorGetTableEntryRGB](#)

# UI Controls

---

This chapter describes the UI controls API as declared in `UIControls.h`.

## UI Control Functions

### UIBrightnessAdjust

|                      |                                                                                                                                                                                                             |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Displays the brightness adjust dialog.                                                                                                                                                                      |
| <b>Declared In</b>   | <code>UIControls.h</code>                                                                                                                                                                                   |
| <b>Prototype</b>     | <code>void UIBrightnessAdjust()</code>                                                                                                                                                                      |
| <b>Parameters</b>    | None                                                                                                                                                                                                        |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                            |
| <b>Comments</b>      | On hardware that supports a brightness setting, this function displays a dialog that allows the user to change the brightness level. On hardware that has a backlight, this function toggles the backlight. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                         |

## **UIContrastAdjust**

- Purpose** Displays the contrast adjust dialog (currently only available on the Palm V™ Connected Organizer).
- Declared In** `UIControls.h`
- Prototype** `void UIContrastAdjust()`
- Parameters** None.
- Result** Returns nothing.
- Compatibility** This function was renamed from `ContrastAdjust` to `UIContrastAdjust` in Palm OS® release 3.5. The `ContrastAdjust` function is available if [3.1 New Feature Set](#) is present.

## **UIPickColor**

- Purpose** Displays a dialog that allows the user to choose a color.
- Declared In** `UIControls.h`
- Prototype** `Boolean UIPickColor (IndexedColorType *indexP, RGBColorType *rgbP, UIPickColorStartType start, const Char *titleP, const Char *tipP)`
- Parameters** `<-> indexP` Index value of the selected color. (See [IndexedColorType](#).) Upon entry, this points to the index value of the color initially selected. Upon return, this points to the index value of the color the user selected. Pass `NULL` to not set or return this value.

|                             |                                                                                                                                                                                                                                                                                                                         |
|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;-&gt; rgbP</code> | RGB value of the selected color. (See <a href="#">RGBColorType</a> .) Upon entry, this points to the RGB value of the color initially selected when the dialog is displayed. Upon return, this points to the RGB value that the user selected. Pass <code>NULL</code> to not set or return this value.                  |
| <code>-&gt; start</code>    | Either <code>UIPickColorStartPalette</code> to display the system palette as a series of color squares or <code>UIPickColorStartRGB</code> to display individual sliders for the red, green, and blue values. This parameter is only used if both <code>indexP</code> and <code>rgbP</code> are not <code>NULL</code> . |
| <code>-&gt; titleP</code>   | String to display as the title of the dialog. Specify <code>NULL</code> to use the default title, which is "Pick Color."                                                                                                                                                                                                |
| <code>-&gt; tipP</code>     | Not used.                                                                                                                                                                                                                                                                                                               |

**Result** Returns `true` if a new color was selected, `false` otherwise.

**Comments** Use this function to allow users to choose a color used in your user interface. (The system never calls `UIPickColor`.)

This function can display two versions of the dialog: palette or RGB. The palette version of the dialog displays a series of squares, each containing a different color defined on the system palette. The `indexP` value contains the index of the square that is initially selected.

The RGB version of the dialog displays three sliders that allow the user to select the level of red, green, and blue in the color. The `rgbP` parameter contains the red, green, and blue values initially shown in the dialog. The sliders only allow values that are defined in the current system color table.

If `indexP` is initially `NULL`, only the RGB dialog is displayed. Similarly, if `rgbP` is `NULL`, only the palette version is displayed. If both parameters are non-`NULL`, the system adds a pull-down list that allows the user to switch between the palette dialog and the RGB dialog, and the `start` parameter controls which version of the

## UI Controls

### UI Control Functions

---

dialog is initially shown. In this case, both `indexP` and `rgbP` contain the value of the user-selected color upon return.

Palm OS 3.5 supports a maximum of 256 colors. The number of possible RGB colors greatly exceeds this amount. For this reason, the chosen RGB may not have an exact match. If this is the case, the `indexP` parameter (if not NULL) contains the closest match using a luminance best-fit if the color lookup table is entirely grayscale (red, green, and blue values for each entry are identical), or a shortest-distance fit in the RGB space is used if the palette contains colors.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

# Miscellaneous User Interface Functions

---

This chapter provides descriptions of miscellaneous user interface functions. It covers the following topics:

- [Miscellaneous User Interface Data Structures](#)
- [Miscellaneous User Interface Functions](#)

You can find declarations for the functions described in this chapter in the header files `AppLaunchCmd.h`, `PhoneLookup.h`, and `UIResources.h`.

## Miscellaneous User Interface Data Structures

The [PhoneNumberLookupCustom](#) function uses these data structures to look up contact information based upon the current cursor position.

### AddressLookupFields

The `AddressLookupFields` enum specifies the fields you can search by and the corresponding fields to return using the `field1` and `field2` elements of the [AddrLookupParamsType](#) structure. For both `field1` and `field2` pass one of the values up to, but not including, `addrLookupFieldCount`.

```
typedef enum {
    addrLookupName,
    addrLookupFirstName,
    addrLookupCompany,
    addrLookupAddress,
    addrLookupCity,
    addrLookupState,
    addrLookupZipCode,
```

## Miscellaneous User Interface Functions

### *Miscellaneous User Interface Data Structures*

---

```
    addrLookupCountry,  
    addrLookupTitle,  
    addrLookupCustom1,  
    addrLookupCustom2,  
    addrLookupCustom3,  
    addrLookupCustom4,  
    addrLookupNote,  
    addrLookupWork,  
    addrLookupHome,  
    addrLookupFax,  
    addrLookupOther,  
    addrLookupEmail,  
    addrLookupMain,  
    addrLookupPager,  
    addrLookupMobile,  
    addrLookupSortField,  
    addrLookupListPhone,  
    addrLookupFieldCount,  
  
    addrLookupNoField = 0xff  
} AddressLookupFields;
```

## **AddrLookupParamsType**

Pass this structure to [PhoneNumberLookupCustom](#) to precisely control the phone number lookup dialog and paste process.

```
typedef struct {  
    Char *title;  
    Char *pasteButtonText;  
    Char lookupString[addrLookupStringLength];  
    AddressLookupFields field1;  
    AddressLookupFields field2;  
    Boolean field2Optional;  
    Boolean userShouldInteract;  
    Char *formatStringP;  
    MemHandle resultStringH;  
    UInt32 uniqueID;  
} AddrLookupParamsType;
```

## Miscellaneous User Interface Functions

### *Miscellaneous User Interface Data Structures*

---

```
typedef AddrLookupParamsType  
*AddrLookupParamsPtr;
```

#### Value Descriptions

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>title</code>           | Title to appear in the title bar. Supply <code>NULL</code> to use the default title.                                                                                                                                                                                                                                                                                                                                       |
| <code>pasteButtonText</code> | Text to appear in paste button. Supply <code>NULL</code> to use the default, "paste".                                                                                                                                                                                                                                                                                                                                      |
| <code>lookupString</code>    | Buffer containing the string to look up. If the string matches only one record, that record is used without presenting the lookup dialog to the user. <a href="#">PhoneNumberLookup</a> and <a href="#">PhoneNumberLookupCustom</a> both set this field based upon the current selection or cursor position.                                                                                                               |
| <code>field1</code>          | Field to search by. This field appears on the left side of the lookup dialog. If the field is the sort field, the search is performed using a binary search. If the field isn't the sort field, searching is performed by a linear search, which can be slow. Supply one of the values in the <a href="#">AddressLookupFields</a> enum to specify the field to search by.                                                  |
| <code>field2</code>          | Field to display on the right. Often displays some information about the person. If it is a phone field and a record has multiple instances of the phone type then the person appears once per instance of the phone type. Either <code>field1</code> or <code>field2</code> may be a phone field, but not both. Supply one of the values in the <a href="#">AddressLookupFields</a> enum to specify the field to display. |

## Miscellaneous User Interface Functions

### *Miscellaneous User Interface Data Structures*

---

|                                 |                                                                                                                                                                                                                                                          |
|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>field2Optional</code>     | A value of <code>true</code> means that the record need not have <code>field2</code> in order to be listed. A value of <code>false</code> indicates that <code>field2</code> is required in order for the record to be listed.                           |
| <code>userShouldInteract</code> | A value of <code>true</code> forces the user to resolve non-unique lookups. A <code>false</code> value means a non-unique and complete lookup causes <code>resultStringH</code> to be set to <code>NULL</code> and <code>uniqueID</code> to be set to 0. |

## Miscellaneous User Interface Functions

### *Miscellaneous User Interface Data Structures*

---

`formatStringP`

Controls the format of the paste string. All characters in the format string are literal unless they identify a field (signified by a caret (^) followed by the field name). For example, the format string “^first - ^home” might result in “Roger - 123-4567”. Allowable field names are:

- name
- first
- company
- address
- city
- state
- zipcode
- country
- title
- custom1
- custom2
- custom3
- custom4
- work
- home
- fax
- other
- email
- main
- pager
- mobile
- listname

| <b>Purpose</b>     | Calls the Address Book application to look up a phone number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Declared In</b> | <code>PhoneLookup.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Prototype</b>   | <code>void PhoneNumberLookup (FieldType *fldP)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <code>-&gt; fldP</code> Field object in which the text to match is found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Result</b>      | Nothing returned; it's locked.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Comments</b>    | <p>This function displays the user's phone list and inserts the chosen name and number (or company name, name, and number, if that's how the user's Address Book preferences indicate that the phone list should be sorted) into the specified field. When displaying the phone list, <code>PhoneNumberLookup</code> scrolls the list to that entry that best matches the supplied field. The match compares the field contents against the name or company name (depending on the user's preferences) as follows:</p> <ul style="list-style-type: none"><li>• If the field contains selected text, <code>PhoneNumberLookup</code> tries to match against the selected text. The selected text is then replaced with the text of the chosen address list entry.</li><li>• If there is no selected text in the field, <code>PhoneNumberLookup</code> matches against the word in which the cursor lies (the match will take place if the cursor is at the beginning, the end, or within a word). The matched word is replaced with the text of the chosen address list entry.</li></ul> |

- If the cursor does not lie within or adjoin a word, `PhoneNumberLookup` displays the address list starting at the first entry, and the text of the chosen entry is inserted at the current position within the text field.

If the user chooses Cancel when the address list is displayed, the field contents are left unaltered. The paste operation takes place through the clipboard so that Undo can be used to restore the field to its previous state.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

### PhoneNumberLookupCustom

**Purpose** Calls the Address Book application to look up a phone number.

**Declared In** `PhoneLookup.h`

**Prototype**  
`void PhoneNumberLookupCustom (FieldType *fldP,  
AddrLookupParamsType *params,  
Boolean useClipboard)`

**Parameters**

|                                 |                                                                                                                                                                                                     |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; fldP</code>         | Field object in which the text to match is found.                                                                                                                                                   |
| <code>&lt;-&gt; params</code>   | A structure that allows full control over the find dialog and the format of the resulting paste string. See <a href="#">AddrLookupParamsType</a> for a description of the fields in this structure. |
| <code>-&gt; useClipboard</code> | If true, <code>PhoneNumberLookupCustom</code> pastes the result into the field through the clipboard, thereby enabling undo.                                                                        |

**Result** Nothing returned; it's locked.

## Miscellaneous User Interface Functions

### *Miscellaneous User Interface Functions*

---

**Comments** This function displays two fields from each record in the user's address list and inserts a formatted string based upon fields in the chosen record into the specified field. When displaying the address list, `PhoneNumberLookupCustom` scrolls the list to that entry that best matches the supplied field. The match compares the field contents against the field specified in the `params` structure's `field1` element as follows:

- If the field contains selected text, `PhoneNumberLookup` tries to match against the selected text. The selected text is then replaced with the text of the chosen address list entry.
- If there is no selected text in the field, `PhoneNumberLookup` matches against the word in which the cursor lies (the match will take place if the cursor is at the beginning, the end, or within a word). The matched word is replaced with the text of the chosen address list entry.
- If the cursor does not lie within or adjoin a word, `PhoneNumberLookup` displays the address list starting at the first entry, and the text of the chosen entry is inserted at the current position within the text field.

`PhoneNumberLookupCustom` copies the portion of the field used for the search—the selected text or the word in which the cursor lies—into the `lookupString` field in the `params` structure prior to replacing that part of the field with the user-selected entry.

If the user chooses `Cancel` when the address list is displayed, the field contents are left unaltered. Depending on the value of the `useClipboard` parameter, the paste operation can take place through the clipboard so that `Undo` can be used to restore the field to its previous state.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Load a constant from a 'tint' resource and return its value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Declared In</b>   | UIResources.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Prototype</b>     | UInt32 ResLoadConstant (UInt16 rscID)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>    | -> rscID                      The ID of the 'tint' resource (symbolically named constantRscType) to load.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Result</b>        | The four-byte value of the constant in the resource, or 0 if the resource could not be found. The return value may be cast as necessary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Comments</b>      | <p>Use this function to load constant values that are stored as 'tint' resources. (All open resource databases are searched for the resource ID you specify.) You should store a constant value as a resource when its value changes depending on the locale.</p> <p>As an example, consider the maximum length of the Alarm Sound trigger label in the Datebook application's preferences panel. The list displayed by this trigger uses the localized name for each sound stored in the system. Because localized names are used, the maximum length that the Datebook application allows for the label differs depending on the current locale. The maximum length is stored as a resource constant so that each overlay database can specify a different value for the constant.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS®, link with the PalmOSGlue library and call ResGlueLoadConstant. For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>See Also</b>      | <a href="#">DmGetResource</a> , <a href="#">DmGet1Resource</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Miscellaneous User Interface Functions

### Miscellaneous User Interface Functions

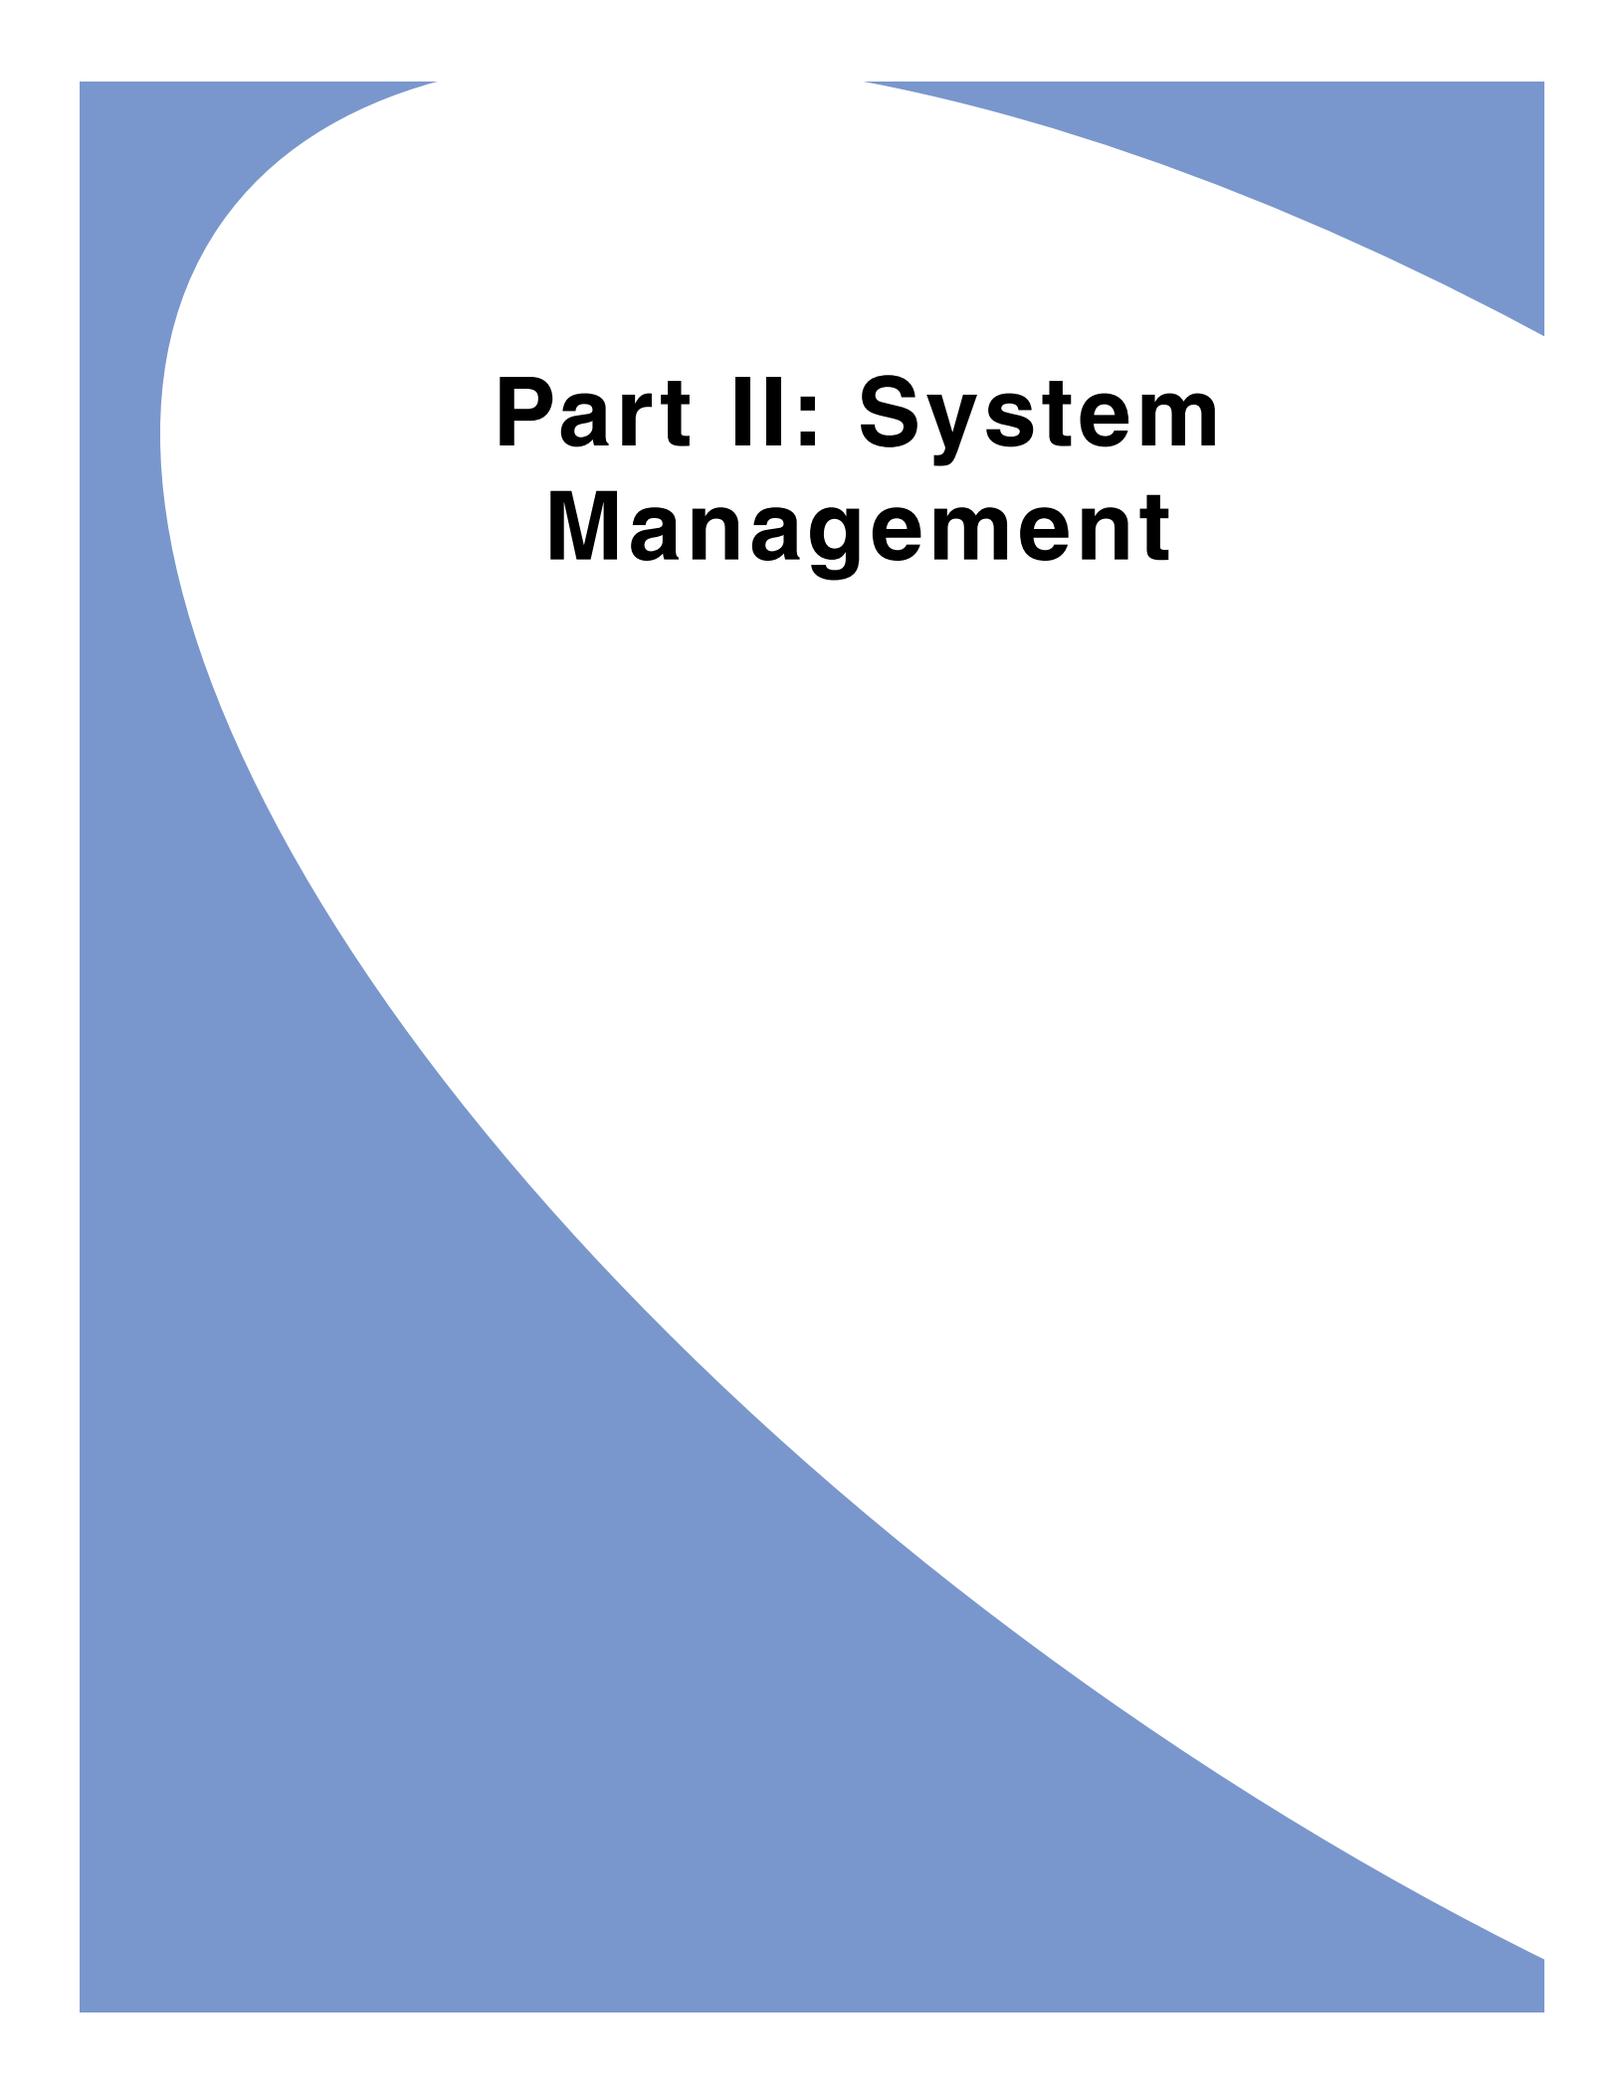

---

#### ResLoadForm

- Purpose** Copy and initialize a form resource. The structures are complete except pointers updating. Pointers are stored as offsets from the beginning of the form.
- Declared In** `UIResources.h`
- Prototype** `void* ResLoadForm (UInt16 rscID)`
- Parameters** `-> rscID` The resource ID of the form.
- Result** The handle of the memory block that the form is in, since the form structure begins with the [WindowType](#), this is also a `WinHandle`.
- Compatibility** If [5.0 New Feature Set](#) is present this function is unimplemented.

#### ResLoadMenu

- Purpose** Copy and initialize a menu resource. The structures are complete except pointers updating. Pointers are stored as offsets from the beginning of the menu.
- Declared In** `UIResources.h`
- Prototype** `void* ResLoadMenu (UInt16 rscID)`
- Parameters** `-> rscID` The resource ID of the menu.
- Result** The handle of the memory block that the form is in, since the form structure begins with the [WindowType](#) this is also a `WinHandle`.

The background is a solid blue color. A large, white, curved shape, resembling a stylized 'C' or a partial circle, is positioned on the left side of the page, extending from the top to the bottom. The text is centered within the white area.

# **Part II: System Management**

# Alarm Manager

---

This chapter provides reference material for the alarm manager:

- [Alarm Manager Functions](#)
- [Application-Defined Functions](#)

The alarm manager API is declared in the header file `AlarmMgr.h`.

For more information on the Alarm Manager, see the section “[Alarms](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Alarm Manager Functions

### AlmGetAlarm

|                    |                                                                             |                                                              |
|--------------------|-----------------------------------------------------------------------------|--------------------------------------------------------------|
| <b>Purpose</b>     | Return the date and time for the application’s alarm, if one is set.        |                                                              |
| <b>Declared In</b> | <code>AlarmMgr.h</code>                                                     |                                                              |
| <b>Prototype</b>   | <code>UInt32 AlmGetAlarm (UInt16 cardNo, LocalID dbID, UInt32* refP)</code> |                                                              |
| <b>Parameters</b>  | -> <code>cardNo</code>                                                      | Number of the storage card on which the application resides. |
|                    | -> <code>dbID</code>                                                        | Local ID of the application.                                 |

## Alarm Manager

### Alarm Manager Functions

---

<- refP                      The alarm's reference value is returned here. This value is passed to the application when the alarm is triggered.

**Result**                      The date and time the alarm will trigger, given in seconds since 1/1/1904; if no alarm is active for the application, 0 is returned for the alarm seconds and the reference value is undefined.

**See Also**                    [AlmSetAlarm](#)

## AlmGetProcAlarm

**Purpose**                      Macro that returns the date and time that a procedure alarm will trigger. Also returns the caller-defined alarm reference value.

**Declared In**                AlarmMgr.h

**Prototype**                 AlmGetProcAlarm (procP, refP)

**Parameters**                -> procP                      Pointer to a function that will be called when alarm is triggered. See [AlmAlarmProcPtr](#).  
                                 <- refP                        A UInt32 pointer to a location where the alarm's reference value is returned. This value is passed to the procedure when the alarm is triggered.

**Result**                      The date and time the alarm will trigger, given in seconds since 1/1/1904; if no alarm is active for the procedure, 0 is returned for the alarm seconds and the reference value is undefined.

**Compatibility**             Implemented only if [3.2 New Feature Set](#) is present.

| 0                  | No error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |           |                                                              |              |                              |            |                                                                                                                                  |                 |                                                                                       |          |                                                                |
| almErrMemory       | Insufficient memory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                                                              |              |                              |            |                                                                                                                                  |                 |                                                                                       |          |                                                                |
| almErrFull         | Alarm table is full.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                                                              |              |                              |            |                                                                                                                                  |                 |                                                                                       |          |                                                                |
| <b>Comments</b>    | <p>This function sets an alarm for the specified application. An application can have only one alarm set at a time. If an alarm for this application has already been set, it is replaced with the new alarm.</p> <p>The <code>alarmSeconds</code> parameter specifies the time at which the alarm will be triggered. As soon as possible after this time, the alarm manager sends the <a href="#">sysAppLaunchCmdAlarmTriggered</a> launch code to the specified application. If there is another alarm that should be set for this application, you can set it in response to this launch code. Following the <code>sysAppLaunchCmdAlarmTriggered</code> launch code, the alarm manager sends a <a href="#">sysAppLaunchCmdDisplayAlarm</a> launch code. This is where your application should do things such as display a modal dialog</p> |           |                                                              |              |                              |            |                                                                                                                                  |                 |                                                                                       |          |                                                                |

## Alarm Manager

### Alarm Manager Functions

---

indicating that the event has occurred. Read more about these launch codes in [Chapter 1, “Application Launch Codes.”](#)

If your application needs access to any particular value to respond to the alarm, pass a pointer to that value in the `ref` parameter. The system will pass this pointer back to the application in the launch codes' parameter blocks.

**See Also** [AlmGetAlarm](#)

## AlmSetProcAlarm

**Purpose** Macro that sets or cancels a procedure alarm.

**Declared In** `AlarmMgr.h`

**Prototype** `AlmSetProcAlarm (procP, ref, alarmSeconds)`

**Parameters**

|                                 |                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; procP</code>        | Pointer to a function that should be called when alarm is triggered. See <a href="#">AlmAlarmProcPtr</a> .                                             |
| <code>-&gt; ref</code>          | A caller-defined <code>UInt32</code> value. This value is passed with the launch code that notifies the application that the alarm has been triggered. |
| <code>-&gt; alarmSeconds</code> | A <code>UInt32</code> indicating the alarm date/time in seconds since 1/1/1904, or 0 to cancel the current alarm (if any).                             |

**Result** Returns one of the following error codes:

|                           |                      |
|---------------------------|----------------------|
| 0                         | No error.            |
| <code>almErrMemory</code> | Insufficient memory. |
| <code>almErrFull</code>   | Alarm table is full. |

**Comments** This macro is similar to the [AlmSetAlarm](#) function, but it specifies a procedure to be called at the specified date and time rather than an application to be launched. With this macro, you can set alarms that are independent of any application. For example, a shared library

can set procedure alarms that call a procedure implemented in the library.

Procedure alarms also differ from regular system alarms in that if they trigger when the device is in sleep mode, the LCD does not light up. Thus, you can use procedure alarms to perform a scheduled task in a manner that is entirely hidden from the user.

---

**IMPORTANT:** Because the `procP` pointer is used to directly call the procedure, the pointer must remain valid from the time `AlmSetProcAlarm` is called to the time the alarm is triggered. If the procedure is in a shared library, you must keep the library open. If the procedure is in a separately loaded code resource, the resource must remain locked until the alarm is triggered. When you close a library or unlock a resource, you must remove any pending alarms. If you don't, the system will crash when the alarm is triggered.

---

**Compatibility**    Implemented only if [3.2 New Feature Set](#) is present.

**See Also**        [AlmGetProcAlarm](#)

## Application-Defined Functions

### **AlmAlarmProcPtr**

**Purpose**            A procedure to be executed when an alarm is triggered.

**Declared In**      `AlarmMgr.h`

**Prototype**        `void (*AlmAlarmProcPtr) (UInt16 almProcCmd, SysAlarmTriggeredParamType *paramP)`

**Parameters**      `-> almProcCmd`    One of the `AlmProcCmdEnum` constants. These are commands that your function must handle. Possible values are:

## Alarm Manager

### Application-Defined Functions

---

`almProcCmdTriggered`

The alarm's date and time has passed and the alarm has been triggered. The function should perform its main task in response to this command.

`almProcCmdReschedule`

A system time change occurred, so the function must reschedule the alarm.

-> `paramP`

Pointer to a `SysAlarmTriggeredParamType` structure. See below.

**Result** Returns nothing.

**Comments** `AlmAlarmProcPtr` procedures are called when an alarm set by [AlmSetProcAlarm](#) is triggered. Your implementation should check the value of `almProcCmd` and respond accordingly.

The `paramP` parameter is a pointer to a `SysAlarmTriggeredParamType` structure. This structure is defined as:

```
typedef struct SysAlarmTriggeredParamType {
    UInt32    ref;
    UInt32    alarmSeconds;
    Boolean    purgeAlarm;
} SysAlarmTriggeredParamType;
```

`ref` and `alarmSeconds` are both values specified in [AlmSetProcAlarm](#) when the alarm is set. The `purgeAlarm` field specifies if the alarm will be removed from the alarm table when the function returns so that the [sysAppLaunchCmdDisplayAlarm](#) launch code is not triggered. This should be `true` for all procedure alarms; the alarm manager set it to `true` for you after your function returns.

If necessary, you can define new values for the `almProcCmd` parameter to call the procedure for something other than a triggered alarm or a system time change. The value you use must be greater than the constant `almProcCmdCustom` as defined in `AlarmMgr.h`.

**Compatibility**    Implemented only if [3.2 New Feature Set](#) is present.

**See Also**        [AlmGetProcAlarm](#)

# Bitmaps

---

This chapter provides information about bitmaps by discussing these topics:

- [Bitmap Data Structures](#)
- [Bitmap Constants](#)
- [Bitmap Resources](#)
- [Bitmap Functions](#)

The header file `Bitmap.h` declares the API that this chapter describes. For more information on bitmaps, see the section “[Bitmaps](#)” on page 123 in the *Palm OS Programmer’s Companion*, vol. I.

## Bitmap Data Structures

### BitmapCompressionType

The `BitmapCompressionType` enum specifies possible bitmap compression types. These are the possible values for the `compressionType` field of [BitmapType](#). You can compress or uncompress a bitmap using a call to [BmpCompress](#).

```
typedef enum {
    BitmapCompressionTypeScanLine = 0,
    BitmapCompressionTypeRLE,
    BitmapCompressionTypePackBits,
    BitmapCompressionTypeEnd,
    BitmapCompressionTypeBest = 0x64,
    BitmapCompressionTypeNone = 0xFF
} BitmapCompressionType;
```

## Bitmaps

### Bitmap Data Structures

---

#### Value Descriptions

|                                            |                                                                                                               |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------|
| <code>BitmapCompressionTypeScanLine</code> | Use scan line compression. Scan line compression is compatible with Palm OS® 2.0 and higher.                  |
| <code>BitmapCompressionTypeRLE</code>      | Use RLE compression. RLE compression is supported in Palm OS 3.5 and higher.                                  |
| <code>BitmapCompressionTypePackBits</code> | Use PackBits compression. PackBits compression is supported in Palm OS 4.0 only.                              |
| <code>BitmapCompressionTypeEnd</code>      | For internal use only.                                                                                        |
| <code>BitmapCompressionTypeBest</code>     | For internal use only.                                                                                        |
| <code>BitmapCompressionTypeNone</code>     | No compression is used.<br><br>This value should only be used as an argument to <a href="#">BmpCompress</a> . |

#### Compatibility

`BitmapCompressionType` is only defined if [3.5 New Feature Set](#) is present. Earlier releases do support compressed bitmaps, but in scan line format only.

#### BitmapDirectInfoType

For direct color bitmaps—each pixel is represented by an RGB triplet rather than a palette index—the `BitmapDirectInfoType` structure follows the color table if one is present, or immediately follows the `BitmapType` if a color table is not present. For direct color bitmaps, only 16 bits per pixel is supported, 5 bits for red, 6 bits for green, and 5 bits for blue.

---

**WARNING!** This structure is documented so that you can directly access the internals of your own bitmap resources. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure;* you cannot cast a direct color bitmap data pointer from a bitmap created by the Palm OS to this structure and expect to be able to correctly access the structure's fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.

---

```
typedef struct BitmapDirectInfoType {
    UInt8 redBits;
    UInt8 greenBits;
    UInt8 blueBits;
    UInt8 reserved;
    RGBColorType transparentColor;
} BitmapDirectInfoType;
```

### Field Descriptions

|                               |                                                                        |
|-------------------------------|------------------------------------------------------------------------|
| <code>redBits</code>          | Number of bits used by the red component in each pixel.                |
| <code>greenBits</code>        | Number of bits used by the green component in each pixel.              |
| <code>blueBits</code>         | Number of bits used by the blue component in each pixel.               |
| <code>reserved</code>         | Must be zero. Reserved for future use.                                 |
| <code>transparentcolor</code> | Contains the red, green, and blue components of the transparent color. |

**Compatibility** `BitmapDirectInfoType` is only defined if [4.0 New Feature Set](#) is present.

### BitmapFlagsType

The `BitmapFlagsType` bit field defines the `flags` field of [BitmapType](#). It specifies the bitmap's attributes.

## Bitmaps

**WARNING!** This structure is documented so that you can directly access the internals of your own bitmap resources. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure; you cannot cast the `flags` field of a bitmap created by the Palm OS to this structure and expect to be able to correctly access the structure's fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.*

---

```
typedef struct BitmapFlagsType {
    UInt16 compressed:1;
    UInt16 hasColorTable:1;
    UInt16 hasTransparency:1;
    UInt16 indirect:1;
    UInt16 forScreen:1;
    UInt16 directColor:1;
    UInt16 indirectColorTable:1;
    UInt16 noDither:1;
    UInt16 reserved:8;
} BitmapFlagsType;
```

#### Field Descriptions

|                            |                                                                                                                                                                                                                                          |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>compressed</code>    | If <code>true</code> , the bitmap is compressed and the <code>compressionType</code> field specifies the compression used. If <code>false</code> , the bitmap is uncompressed. The <a href="#">BmpCompress</a> function sets this field. |
| <code>hasColorTable</code> | If <code>true</code> , the bitmap has its own color table. If <code>false</code> , the bitmap uses the system color table. You specify whether the bitmap has its own color table when you create the bitmap.                            |

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>hasTransparency</code> | <p>If <code>true</code>, the OS will not draw pixels that have a value equal to the <code>transparentIndex</code>. If <code>false</code>, the bitmap has no transparency value. You specify the transparent color when you create the bitmap using <code>Constructor</code>, or you can specify it programmatically with <a href="#">BmpSetTransparentValue</a>. To obtain the value of this field, call <a href="#">BmpGetTransparentValue</a>.</p>                                |
| <code>indirect</code>        | <p>If <code>true</code>, the address to the bitmap's data is stored where the bitmap itself would normally be stored. The actual bitmap data is stored elsewhere. If <code>false</code>, the bitmap data is stored directly following the bitmap header or directly following the bitmap's color table if it has one. Never set this flag.</p> <p>Note that this flag is supported for bitmaps created by Palm OS only; this flag is not used in user-created bitmap resources.</p> |
| <code>forScreen</code>       | <p>If <code>true</code>, bitmap intended for the display (screen) window. Never set this flag.</p> <p>Note that this flag is supported for bitmaps created by Palm OS only; this flag is not used in user-created bitmap resources.</p>                                                                                                                                                                                                                                             |
| <code>directColor</code>     | <p>If <code>true</code>, bitmap is a direct color (RGB) bitmap.</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Bitmaps

### Bitmap Data Structures

---

`indirectColorTable` If `true`, and if `hasColorTable` is `true`, a pointer to the bitmap's color table immediately follows the [BitmapType](#) structure. If `false`, and `hasColorTable` is `true`, the color table immediately follows the [BitmapType](#) structure. If `hasColorTable` is `false`, `indirectColorTable` is ignored. The `indirect` bit uses similar logic: if both the color table and the bitmap data are indirect, the color table pointer precedes the bitmap data pointer.

Note that this flag is supported for bitmaps created by Palm OS only; this flag is not used in user-created bitmap resources.

`noDither` If `true`, the blitter does not dither the bitmap. If `false`, the source bitmap is dithered if it has a bit depth greater than the destination bitmap.

`reserved` Reserved for future use.

#### Compatibility

The `hasTransparency`, `indirect`, and `forScreen` flags are only defined if [3.5 New Feature Set](#) is present. The `directColor` flag is only defined if [4.0 New Feature Set](#) is present. The `indirectColorTable` and `noDither` flags are only defined if the [High-Density Display Feature Set](#) is present.

### BitmapPtr

The `BitmapPtr` type defines a pointer to a [BitmapType](#) structure.

```
typedef BitmapType *BitmapPtr;
```

### BitmapType

The `BitmapType` structure represents that which is common to all `BitmapTypeVx` structures ([BitmapTypeV0](#), [BitmapTypeV1](#), [BitmapTypeV2](#), and [BitmapTypeV3](#)). The `BitmapType` structures define both the bitmaps representing the window display and

bitmap resources ('Tbmp' and 'tAIB') that you create using Constructor or some other application and load into your program.

Because BitmapType is merely a portion of the BitmapTypeVx structures, you should never do sizeof(BitmapType).

---

**WARNING!** This structure is documented so that you can directly access the internals of your own bitmap resources. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure; you cannot cast a bitmap created by the Palm OS to this structure and expect to be able to correctly access the structure's fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.*

---

```
typedef struct BitmapType {
    Int16 width;
    Int16 height;
    UInt16 rowBytes;
    BitmapFlagsType flags;
    UInt8 pixelSize;
    UInt8 version;
} BitmapType;

typedef BitmapType* BitmapPtr;
```

### Field Descriptions

|          |                                                                                                                                                                      |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| width    | The width of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.                     |
| height   | The height of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.                    |
| rowBytes | The number of bytes stored for each row of the bitmap where height is the number of rows. Use <a href="#">BmpGetDimensions</a> to obtain the contents of this field. |

## Bitmaps

|           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags     | The bitmap's attributes. See <a href="#">BitmapFlagsType</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| pixelSize | The pixel depth. Currently supported pixel depths are 1, 2, 4, and 8-bit. You specify this value when you create the bitmap. Use <a href="#">BmpGetBitDepth</a> to access the contents of this field.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| version   | The version of bitmap encoding used. See " <a href="#">Bitmap Constants</a> " on page 535. The value in this field determines the data structure to use when interpreting the fields following version: a value of <code>BitmapVersionZero</code> (0) corresponds to <a href="#">BitmapTypeV0</a> , <code>BitmapVersionOne</code> (1) corresponds to <a href="#">BitmapTypeV1</a> , <code>BitmapVersionTwo</code> (2) corresponds to <a href="#">BitmapTypeV2</a> , and <code>BitmapVersionThree</code> (3) corresponds to <a href="#">BitmapTypeV3</a> . Use <a href="#">BmpGetVersion</a> to obtain the contents of this field. |

**Comments** Note the following about the `BitmapType` structures:

- None of these fields contains the actual bitmap data. Instead, the bitmap data is stored immediately following the `BitmapTypeVx` (which one depends on the value of the version field) header structure. If the bitmap has its own color table, the color table is stored in between the header and the data. If the bitmap has a pixel size of 16, and the bitmap is `BitmapTypeV2`, the `BitmapDirectInfoType` structure is stored between the header and the data. You can retrieve a bitmap's data by passing its `BitmapType` structure to `BmpGetBits`, and you can retrieve its color table with `BmpGetColorTable`.
- Unlike most other user interface structures, the `BitmapType` does not store the bitmap's location on the screen. The `WindowType` or the `FormBitmapType` with which this bitmap is associated contains that information.
- A bitmap may be part of a bitmap family. A bitmap family is a group of bitmaps, each containing the same drawing but at

a different pixel depth (see “[Bitmaps](#)” on page 123 of the *Palm OS Programmer’s Companion*, vol. I). When requested to draw a bitmap family, the operating system chooses a member of the bitmap family based upon the bitmap density and pixel depth; see “[Bitmap Families](#)” on page 18 for the algorithm that the [High-Density Display Feature Set](#) uses to determine which one to choose.

---

## **BitmapTypeV0**

Structure corresponding to the version 0 encoding of a bitmap. Version 0 encoding is supported in Palm OS 1.0 and later.

Generally you work with pointers to [BitmapType](#) structures; if the structure’s version is `BitmapVersionZero`, the structure is of type `BitmapTypeV0`.

---

**WARNING!** This structure is documented so that you can directly access the internals of your own bitmap resources. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure; you cannot cast a bitmap created by the Palm OS to this structure and expect to be able to directly access the structure’s fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.*

---

```
typedef struct BitmapTypeV0 {
    Int16 width;
    Int16 height;
    UInt16 rowBytes;
    BitmapFlagsType flags;
    UInt16 reserved[4];
} BitmapTypeV0;

typedef BitmapTypeV0 *BitmapPtrV0;
```

## Bitmaps

#### Field Descriptions

|          |                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| width    | The width of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.                                                                                                                                                                                                                                                                                              |
| height   | The height of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.                                                                                                                                                                                                                                                                                             |
| rowBytes | The number of bytes stored for each row of the bitmap where height is the number of rows. Use <a href="#">BmpGetDimensions</a> to access this field.                                                                                                                                                                                                                                                                                          |
| flags    | The bitmap's attributes. See <a href="#">BitmapFlagsType</a> . Only the compressed flag is defined for <code>BitmapTypeV0</code> structures.                                                                                                                                                                                                                                                                                                  |
| reserved | Reserved. These values are set to zero. Note that in the <code>BitmapTypeV0</code> structure, the <code>pixelSize</code> and <code>version</code> fields, defined in <a href="#">BitmapType</a> , do not exist. They coincide with the reserved array, however, and this array was initialized to zero when the bitmap was created. The operating system recognizes that a <code>pixelSize</code> of zero means that the bitmap's depth is 1. |

**Compatibility** `BitmapTypeV0` is defined only if [High-Density Display Feature Set](#) is present.

---

### New **BitmapTypeV1**

Structure corresponding to the version 1 encoding of a bitmap. Version 1 encoding is supported in Palm OS 3.0 and later.

Generally you work with pointers to [BitmapType](#) structures; if the structure's version is `BitmapVersionOne`, the structure is of type `BitmapTypeV1`.

---

**WARNING!** This structure is documented so that you can directly access the internals of your own bitmap resources. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure;* you cannot cast a bitmap created by the Palm OS to this structure and expect to be able to directly access the structure's fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.

---

```
typedef struct BitmapTypeV1 {
    Int16 width;
    Int16 height;
    UInt16 rowBytes;
    BitmapFlagsType flags;
    UInt8 pixelSize;
    UInt8 version;
    UInt16 nextDepthOffset;
    UInt16 reserved[2];
} BitmapTypeV1;

typedef BitmapTypeV1* BitmapPtrV1;
```

### Field Descriptions

|          |                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| width    | The width of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.     |
| height   | The height of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.    |
| rowBytes | The number of bytes stored for each row of the bitmap where height is the number of rows. Use <a href="#">BmpGetDimensions</a> to access this field. |

|                 |                                                                                                                                                                                                                                                                                                                                 |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags           | The bitmap's attributes. See <a href="#">BitmapFlagsType</a> . Only the compressed and hasColorTable flags are defined for BitmapTypeV1 structures.                                                                                                                                                                             |
| pixelSize       | The pixel depth. Currently supported pixel depths are 1, 2, and 4-bit. You specify this value when you create the bitmap. Use <a href="#">BmpGetBitDepth</a> to obtain the contents of this field.                                                                                                                              |
| version         | The version of bitmap encoding used. This field has a value of BitmapVersionOne (1) for BitmapTypeV1 structures. Use <a href="#">BmpGetVersion</a> to obtain the contents of this field.                                                                                                                                        |
| nextDepthOffset | For bitmap families, this field specifies the start of the next bitmap in the family. The value it contains is the number of 4-byte words to the next <a href="#">BitmapType</a> from the beginning of this one. If the bitmap is not part of a bitmap family or it is the last bitmap in the family, the nextDepthOffset is 0. |
| reserved        | Reserved.                                                                                                                                                                                                                                                                                                                       |

**Compatibility** [BitmapTypeV1](#) is defined only if [High-Density Display Feature Set](#) is present.

---

### New **BitmapTypeV2**

Structure corresponding to the version 2 encoding of a bitmap. Version 2 encoding is supported in Palm OS 3.5 and later.

Generally you work with pointers to [BitmapType](#) structures; if the structure's version is [BitmapVersionTwo](#) (2), the structure is of type [BitmapTypeV2](#).

---

**WARNING!** This structure is documented so that you can directly access the internals of bitmaps that you create. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure; you cannot cast a bitmap created by the Palm OS to this structure and expect to be able to directly access the structure's fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.*

---

```
typedef struct BitmapTypeV2 {
    Int16 width;
    Int16 height;
    UInt16 rowBytes;
    BitmapFlagsType flags;
    UInt8 pixelSize;
    UInt8 version;
    UInt16 nextDepthOffset;
    UInt8 transparentIndex;
    UInt8 compressionType;
    UInt16 reserved;
} BitmapTypeV2;

typedef BitmapTypeV2* BitmapPtrV2;
```

### Field Descriptions

|          |                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| width    | The width of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.     |
| height   | The height of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.    |
| rowBytes | The number of bytes stored for each row of the bitmap where height is the number of rows. Use <a href="#">BmpGetDimensions</a> to access this field. |

## Bitmaps

### Bitmap Data Structures

---

|                  |                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| flags            | The bitmap's attributes. See <a href="#">BitmapFlagsType</a> . Only the compressed, hasColorTable, hasTransparency, indirect, forScreen, and directColor flags are defined for BitmapTypeV2 structures. Note that the indirect and forScreen flags are system-only flags that are not used in user-created bitmap resources.                                                             |
| pixelSize        | The pixel depth. Currently supported pixel depths are 1, 2, 4, 8, and 16-bit. You specify this value when you create the bitmap. Use <a href="#">BmpGetBitDepth</a> to obtain the contents of this field.                                                                                                                                                                                |
| version          | The version of bitmap encoding used. This field has a value of BitmapVersionTwo (2) for BitmapTypeV2 structures. Use <a href="#">BmpGetVersion</a> to obtain the contents of this field.                                                                                                                                                                                                 |
| nextDepthOffset  | For bitmap families, this field specifies the start of the next bitmap in the family. The value it contains is the number of 4-byte words to the next BitmapType from the beginning of this one. If the bitmap is not part of a bitmap family or it is the last bitmap in the family, the nextDepthOffset is 0.                                                                          |
| transparentIndex | The color index for the transparent color. Only used for version 2 bitmaps and only when the hasTransparency flag is set (see <a href="#">BitmapFlagsType</a> ). You specify this value when you create the bitmap using Constructor, or programmatically with <a href="#">BmpSetTransparentValue</a> . To obtain the value of this field, call <a href="#">BmpGetTransparentValue</a> . |

|                 |                                                                                                                                                                                                                                                                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| compressionType | The compression type used. Only used for version 2 bitmaps and only when the compressed flag is set (see <a href="#">BitmapFlagsType</a> ). See <a href="#">BitmapCompressionType</a> for possible values. The <a href="#">BmpCompress</a> function sets this field, and the <a href="#">BmpGetCompressionType</a> function obtains its value. |
| reserved        | Reserved.                                                                                                                                                                                                                                                                                                                                      |

**Compatibility** [BitmapTypeV2](#) is defined only if [High-Density Display Feature Set](#) is present.

---

## **New** [BitmapTypeV3](#)

Structure corresponding to the version 3 encoding of a bitmap. Version 3 encoding is supported if the [High-Density Display Feature Set](#) is present.

Generally you work with pointers to [BitmapType](#) structures; if the structure's version is [BitmapVersionThree](#) (3), the structure is of type [BitmapTypeV3](#).

[BmpCreate](#) allocates and initializes a [BitmapTypeV2](#) structure. To create a [BitmapTypeV3](#) structure, use [BmpCreateBitmapV3](#) and supply the data pointer and optional color table pointer.

In earlier versions of the [BitmapTypeVx](#) structure, the size of compressed bitmap data is stored in a 16-bit field preceding the bitmap data. With the version 3 structure, the size is stored in a 32-bit field.

The [BitmapTypeV3](#) structure has fields that identify how each pixel is stored ([pixelFormat](#)) and which color, if any, is "transparent" ([transparentValue](#)). Because of this, you don't use a [BitmapDirectInfoType](#) structure in conjunction with a [BitmapTypeV3](#) structure.

## Bitmaps

### Bitmap Data Structures

---

---

**WARNING!** This structure is documented so that you can directly access the internals of bitmaps that you create. *Bitmaps created by Palm OS are not guaranteed to adhere to this structure; you cannot cast a bitmap created by the Palm OS to this structure and expect to be able to directly access the structure's fields. Always use accessor functions to access the contents of user interface structures created by Palm OS.*

---

```
typedef struct BitmapTypeV3 {
    Int16 width;
    Int16 height;
    UInt16 rowBytes;
    BitmapFlagsType flags;
    UInt8 pixelSize;
    UInt8 version;
    UInt8 size;
    UInt8 pixelFormat;
    UInt8 unused;
    UInt8 compressionType;
    UInt16 density;
    UInt32 transparentValue;
    UInt32 nextBitmapOffset;
} BitmapTypeV3;

typedef BitmapTypeV3* BitmapPtrV3;
```

#### Field Descriptions

|        |                                                                                                                                                   |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| width  | The width of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field.  |
| height | The height of the bitmap in pixels. You specify this value when you create the bitmap. Use <a href="#">BmpGetDimensions</a> to access this field. |

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rowBytes</code>    | The number of bytes stored for each row of the bitmap where height is the number of rows. Use <a href="#">BmpGetDimensions</a> to access this field.                                                                                                                                                                                                                                                                                                          |
| <code>flags</code>       | The bitmap's attributes. See <a href="#">BitmapFlagsType</a> . Note that the <code>indirect</code> , <code>forScreen</code> , and <code>indirectColorTable</code> flags are system-only fields that are not used in user-created bitmap resources.                                                                                                                                                                                                            |
| <code>pixelSize</code>   | The pixel depth. Currently supported pixel depths are 1, 2, 4, and 8-bit. You specify this value when you create the bitmap. Use <a href="#">BmpGetBitDepth</a> to obtain the value of this field.                                                                                                                                                                                                                                                            |
| <code>version</code>     | The version of bitmap encoding used. This field has a value of <code>BitmapVersionThree</code> (3) for <code>BitmapTypeV3</code> structures. The high bit of the version field is set if the bitmap data structure uses the native ARM format, with little-endian fields. <code>Bitmap.h</code> contains a bit mask, <code>BitmapVersionMaskLE</code> , that can be used to detect this. Use <a href="#">BmpGetVersion</a> to obtain the value of this field. |
| <code>size</code>        | The size of this structure, in bytes. This field does not include the size of the color table or the size of the bitmap data. Use <a href="#">BmpGetSizes</a> to obtain the value of this field.                                                                                                                                                                                                                                                              |
| <code>pixelFormat</code> | An enumerated constant representing the format of the pixel data. See <a href="#">PixelFormatType</a> for the supported values.                                                                                                                                                                                                                                                                                                                               |
| <code>unused</code>      | Not used.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Bitmaps

### Bitmap Data Structures

---

- `compressionType` The compression type used; 0 if the bitmap is not compressed. Only used when the compressed flag is set (see [BitmapFlagsType](#)). See [BitmapCompressionType](#) for possible values. The [BmpCompress](#) function sets this field, and the [BmpGetCompressionType](#) function obtains its value.
- `density` Value used by the blitter to determine how to stretch or shrink the bitmap data. For the screen bitmap, this field represents the screen density. For handhelds with low-density displays, this field is initialized to `kDensityLow`. For handhelds with double-density displays, this field is initialized to `kDensityDouble`. See [DensityType](#) for the full set of values that this field can assume. Set this field with [BmpSetDensity](#), and obtain its value with [BmpGetDensity](#).
- `transparentValue` If this structure represents a bitmap with a bit depth of 8 or less, this field contains the bitmap's transparent index. If the bitmap has a bit depth of 16, the 16-bit transparent RGB color is stored in this field. You specify this value when you create the bitmap using [Constructor](#), or programmatically with [BmpSetTransparentValue](#). To obtain the value of this field, call [BmpGetTransparentValue](#).
- `nextBitmapOffset` A 32-bit value that indicates the number of bytes to the next bitmap in the family. If the bitmap is not part of a bitmap family or it is the last bitmap in the family, the `nextBitmapOffset` is 0.

**Compatibility** `BitmapTypeV3` is defined only if [High-Density Display Feature Set](#) is present.

## ColorTableType

The `ColorTableType` structure defines a color table. Bitmaps can have color tables attached to them; however, doing so is not recommended for performance reasons.

---

**WARNING!** PalmSource, Inc. does not support or provide backward compatibility for the `ColorTableType` structure. Never access its structure members directly, or your code may break in future versions. Use [BmpGetColortable](#) to access this structure. Use the information below for debugging purposes only.

---

```
typedef struct ColorTableType {
    UInt16          numEntries;
    // RGBColorType entry[];
} ColorTableType;
```

### Field Descriptions

`numEntries`      The number of entries in table. High bits (`numEntries > 256`) reserved.

The color table entries themselves are of type [RGBColorType](#), and there is one per `numEntries`. Use the macro [ColorTableEntries](#) to retrieve these entries.

Care should be taken not to confuse a full color table (which includes the count) with an array of RGB color values. Some routines operate on entire color tables; others operate on lists of color entries.

**Compatibility**      `ColorTableType` is defined only if [3.5 New Feature Set](#) is present.

---

## **New** DensityType

The density of the bitmap (see “[Display Density](#)” on page 75 of the *Palm OS Programmer’s Companion*, vol. I for a definition of display density). Density is only supported in [BitmapType](#) structures with

## Bitmaps

### Bitmap Data Structures

---

a version greater than 2; if a given `BitmapType` structure is version 2 or lower, it is assumed to contain low-density data.

The blitter uses the density field in the source and destination bitmaps to determine an appropriate scaling factor. When scaling down from a density of `kDensityDouble` to `kDensityLow`, the blitter must shrink the bitmap data. This will almost always result in a poorer-quality image when compared with a bitmap that was created with a density of `kDensityLow`.

The various `DensityType` values should not be interpreted as representing pixels per inch.

```
typedef enum {
    kDensityLow = 72,
    kDensityOneAndAHalf = 108,
    kDensityDouble = 144,
    kDensityTriple = 216,
    kDensityQuadruple = 288
} DensityType
```

### Value Descriptions

|                                  |                                                                                                                                                                                                              |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>kDensityLow</code>         | Low (single) density. A low-density screen is 160x160 pixels.                                                                                                                                                |
| <code>kDensityOneAndAHalf</code> | “One and a half” density. A one-and-a-half-density display is 240x240 pixels; this would most likely be used on a handheld with a 240x320 screen where the bottom portion is used as a “soft Graffiti” area. |
| <code>kDensityDouble</code>      | Double density when compared with <code>kDensityLow</code> . A double-density screen is 320x320 pixels.                                                                                                      |
| <code>kDensityTriple</code>      | Triple density when compared with <code>kDensityLow</code> . A triple-density screen is 480x480 pixels.                                                                                                      |
| <code>kDensityQuadruple</code>   | Quadruple density when compared with <code>kDensityLow</code> . A quadruple-density screen is 640x640 pixels.                                                                                                |

---

**IMPORTANT:** Not all densities listed in the `DensityType` enum are supported by a given version of the High-Density Display feature set. For Palm OS 5, only `kDensityLow` and `kDensityDouble` are supported.

---

**Compatibility** `DensityType` is defined only if [High-Density Display Feature Set](#) is present.

## **New** `PixelFormatType`

Pixel formats defined for use with [BitmapTypeV3](#) structures.

```
typedef enum {
    pixelFormatIndexed,
    pixelFormat565
    pixelFormat565LE,
    pixelFormatIndexedLE
} PixelFormatType;
```

### **Field Descriptions**

|                                   |                                                                                                                                                                              |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pixelFormatIndexed</code>   | Each pixel is represented by a palette index.                                                                                                                                |
| <code>pixelFormat565</code>       | Each pixel is represented by an RGB triplet stored in 16-bits: 5 red bits, 6 green bits, and 5 blue bits.                                                                    |
| <code>pixelFormat565LE</code>     | Similar to <code>pixelFormat565</code> , except that the 16 bits of the RGB triplet are stored as little-endian. This pixel format is not supported in user-created bitmaps. |
| <code>pixelFormatIndexedLE</code> | Similar to <code>pixelFormatIndexed</code> , except that the pixels within a byte are stored as little-endian. This pixel format is not supported in user-created bitmaps.   |

## Bitmaps

### Bitmap Data Structures

---

**Compatibility** PixelFormatType is defined only if [High-Density Display Feature Set](#) is present.

## RGBColorType

The RGBColorType structure defines a color. It is used as an entry in the color table. RGBColorTypes can also be created manually and passed to several user interface functions.

```
typedef struct RGBColorType {
    UInt8 index;
    UInt8 r;
    UInt8 g;
    UInt8 b;
} RGBColorType;
```

### Field Descriptions

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| index | The index of this color in the color table. Not all functions that use RGBColorType use the index field.<br><br>Direct bitmaps support no more than 256 colors. The number of possible RGB colors greatly exceeds this amount. For this reason, some drawing functions use a color look up table (CLUT). If the CLUT is used, the index field contains the index of an available color that is the closest match to the color specified by the r, g, and b fields. |
| r     | Amount of red (0 to 255).                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| g     | Amount of green (0 to 255).                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| b     | Amount of blue (0 to 255).                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Compatibility** RGBColorType is defined only if [3.5 New Feature Set](#) is present.

## Bitmap Constants

| Constant                        | Value | Description                                                                                                                                                                                                                                                                |
|---------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>BitmapVersionZero</code>  | 0     | Uses the version 0 encoding of a bitmap. Version 0 encoding is supported in Palm OS 1.0 and later.                                                                                                                                                                         |
| <code>BitmapVersionOne</code>   | 1     | Uses the version 1 encoding of a bitmap. Version 1 encoding is supported in Palm OS 3.0 and later.<br><br>PalmRez automatically creates version 1 bitmaps unless you have specified a transparency index or a compressed type when creating the bitmap in Constructor.     |
| <code>BitmapVersionTwo</code>   | 2     | Uses the version 2 encoding of a bitmap. Palm OS 3.5 and later supports version 2 bitmaps. Version 2 bitmaps either use the transparency index or are compressed. If you programmatically create a bitmap using <a href="#">BmpCreate</a> , a version 2 bitmap is created. |
| <code>BitmapVersionThree</code> | 3     | Uses the version 3 encoding of a bitmap. Version 3 bitmaps are supported only if the <a href="#">High-Density Display Feature Set</a> is present.                                                                                                                          |

## Bitmap Resources

You can create a bitmap resource and include it as part of your application's PRC file. Use the resource type `'Tbmp'` for most images and the resource type `'tAIB'` for application icons. Symbolically, these two resource types are `bitmapRsc` and `iconType`, respectively.

Note that if you are creating a bitmap or a bitmap family in Constructor, you create a `'tbmf'` resource (or `'taif'` resource for icons) and one or more 'PICT' images. The PalmRez post linker converts them into a single `'Tbmp'` or `'tAIB'` resource. Note that

## Bitmaps

### Bitmap Functions

---

the PalmRez post linker takes PICT images even on the Microsoft Windows operating system.

## Bitmap Functions

### BmpBitsSize

|                      |                                                                                                                                                                                                                          |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the size of the bitmap's data.                                                                                                                                                                                    |
| <b>Declared In</b>   | Bitmap.h                                                                                                                                                                                                                 |
| <b>Prototype</b>     | UInt16 BmpBitsSize (const BitmapType *bitmapP)                                                                                                                                                                           |
| <b>Parameters</b>    | -> bitmapP          Pointer to the bitmap. (See <a href="#">BitmapType</a> .)                                                                                                                                            |
| <b>Result</b>        | Returns the size in bytes of the bitmap's data, excluding the header and the color table.                                                                                                                                |
| <b>Comments</b>      | This function returns the bitmap's data size even if the bitmap's indirect flag is set. (See <a href="#">BitmapFlagsType</a> .)<br>If the bitmap is compressed, this function returns the compressed size of the bitmap. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                      |
| <b>See Also</b>      | <a href="#">BmpSize</a> , <a href="#">BmpColortableSize</a> , <a href="#">BmpGetBits</a>                                                                                                                                 |

## **BmpColortableSize**

- Purpose** Return the size of the bitmap's color table.
- Declared In** `Bitmap.h`
- Prototype**

```
UInt16 BmpColortableSize  
(const BitmapType *bitmapP)
```
- Parameters** `-> bitmapP` Pointer to the bitmap. (See [BitmapType](#).)
- Result** Returns the size in bytes of the bitmap's color table or 0 if the bitmap does not use its own color table.
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [BmpBitsSize](#), [BmpSize](#), [BmpGetColortable](#)

## **BmpCompress**

- Purpose** Compress or uncompress a bitmap.
- Declared In** `Bitmap.h`
- Prototype**

```
Err BmpCompress (BitmapType *bitmapP,  
BitmapCompressionType compType)
```
- Parameters** `-> bitmapP` Pointer to the bitmap to compress. (See [BitmapType](#).)
- `-> compType` The type of compression to use. (See [BitmapCompressionType](#).) If set to `BitmapCompressionTypeNone` and `bitmapP` is compressed, this function uncompresses the bitmap.
- Result** Returns one of the following values:
- |                      |          |
|----------------------|----------|
| <code>errNone</code> | Success. |
|----------------------|----------|

## Bitmaps

### Bitmap Functions

---

`sysErrParamErr` Either the `compType` parameter does not specify a compression type or the bitmap is already compressed, is in the storage heap, or represents the screen.

`sysErrNoFreeResource`  
There is not enough memory available to complete the operation.

**Comments** This function performs the specified compression and resizes the bitmap's allocated memory. The bitmap must be in the dynamic heap.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [BmpGetCompressionType](#)

## BmpCreate

**Purpose** Create a bitmap.

**Declared In** `Bitmap.h`

**Prototype** `BitmapType *BmpCreate (Coord width, Coord height, UInt8 depth, ColorTableType *colortableP, UInt16 *error)`

**Parameters**

|           |                                                                                                                                                  |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| -> width  | The width of the bitmap in pixels. Must not be 0.                                                                                                |
| -> height | The height of the bitmap in pixels. Must not be 0.                                                                                               |
| -> depth  | The pixel depth of the bitmap. Must be 1, 2, 4, 8, or 16. This value is used as the <code>pixelSize</code> field of <a href="#">BitmapType</a> . |

-> `colortableP` A pointer to the color table associated with the bitmap, or NULL if the bitmap should not include a color table. If specified, the number of colors in the color table must match the `depth` parameter. (2 for 1-bit, 4 for 2-bit, 16 for 4-bit, and 256 for 8-bit). 16-bit bitmaps do not use a color table.

<- `error` Contains the error code if an error occurs.

**Result** Returns a pointer to the new bitmap structure (see [BitmapType](#)) or NULL if an error occurs. The parameter `error` contains one of the following:

`errNone` Success.

`sysErrParamErr` The width, height, depth, or `colorTableP` parameter is invalid. See the descriptions above for acceptable values.

`sysErrNoFreeResource` There is not enough memory available to allocate the structure.

**Comments** This function creates an uncompressed, non-transparent `BitmapVersionTwo` bitmap with the width, height, and depth that you specify. To create a `BitmapVersionThree` bitmap use `BmpCreate` and pass the results to [BmpCreateBitmapV3](#).

If you pass a color table, the bitmap's `hasColorTable` flag is set. For performance reasons, attaching a custom color table to a bitmap is strongly discouraged. An alternative is to use the [WinPalette](#) command to change the color table as needed, draw the bitmap, and then undo your changes after you have finished displaying the bitmap.

`BmpCreate` allocates sufficient memory on the dynamic heap to hold the bitmap and initializes all of its pixels to white. To change the bitmap's contents, use the window drawing functions. First, you must use [WinCreateBitmapWindow](#) to create an off screen window wrapper around the bitmap, then draw to that window. For example:

## Bitmaps

### Bitmap Functions

---

```
BitmapType *bmpP;
WinHandle win;
Err error;
RectangleType onScreenRect;

bmpP = BmpCreate(10, 10, 8, NULL, &error);
if (bmpP) {
    win = WinCreateBitmapWindow(bmpP, &error);
    if (win) {
        WinSetDrawWindow(win);
        WinDrawLines(win, ...);
        /* etc */
        WinSetWindowBounds(win, onScreenRect);
    }
}
```

You cannot use this function to create a bitmap written directly to a database; that is, you must create the bitmap on the dynamic heap first, then write it to the storage heap.

It is not necessary to use `BmpCreate` to load a bitmap stored in a resource. Instead, you simply load the resource and lock its handle. The returned pointer is a pointer to a `BitmapType`. For example:

```
MemHandle resH =
    DmGetResource (bitmapRsc, rscID);
BitmapType *bitmap = MemHandleLock (resH);
```

Bitmaps 64 Kb and greater are now supported with Palm OS 4.0.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [BmpCreateBitmapV3](#), [BmpDelete](#)

---

## **New** **BmpCreateBitmapV3**

- Purpose** Create a version 3 bitmap from an existing bitmap, an existing set of data bits, and, optionally, a color table.
- Declared In** `Bitmap.h`
- Prototype**
- ```
BitmapTypeV3 *BmpCreateBitmapV3  
(const BitmapType *bitmapP, UInt16 density,  
const void *bitsP,  
const ColorTableType *colorTableP)
```
- Parameters**
- > `bitmapP` Pointer to a valid bitmap from which the version 3 bitmap is to be created. See [BitmapType](#).
  - > `density` Density of the returned bitmap. If 0, the returned bitmap's density is set to the default value of `kDensityLow`.
  - > `bitsP` Pointer to the bitmap image data. Note that the bitmap data can be located in the storage heap, but then the bitmap should be treated as read-only. You must use `DmWrite` to write to the storage heap; blitting to it causes a system error.
  - > `colorTableP` Pointer to a color table, or `NULL` to use `bitmapP`'s color table, if one exists.
- Result** Returns a version 3 bitmap, or `NULL` if the bitmap could not be created from the specified bitmap, bitmap data, and optional color table.
- Comments** You can use this function when the bitmap data is stored in the storage heap as bands of raster data. Rather than allocating several bitmap structures, one for each band, use this function to allocate a single bitmap, and have the structure point to each band successively. This is typically used with high-density bitmaps that cannot be stored entirely within 64k.

## Bitmaps

### Bitmap Functions

---

---

**WARNING!** Due to a limitation in the way that this function is implemented, `BitmapCreateBitmapV3` doesn't work with compressed bitmaps. Don't pass bitmaps to this function that have the `compressed` flag set.

---

The returned bitmap structure is allocated from the system heap. After your application is done with it, dispose of it by calling [BmpDelete](#).

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [BmpCreate](#)

## BmpDelete

**Purpose** Delete a bitmap structure.

**Declared In** `Bitmap.h`

**Prototype** `Err BmpDelete (BitmapType *bitmapP)`

**Parameters** `-> bitmapP` Pointer to the structure of the bitmap to be deleted. (See [BitmapType](#).)

**Result** Returns `errNone` upon success, `sysErrParamErr` if the bitmap's `forScreen` flag is set or the bitmap resides in the storage heap. Returns one of the memory errors if the freeing pointer fails.

**Comments** Only delete bitmaps that have been created using [BmpCreate](#). You cannot use this function on a bitmap located in a database. To delete a bitmap from a database, use the standard data manager calls.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

## BmpGetBits

- Purpose** Retrieve the bitmap's data.
- Declared In** `Bitmap.h`
- Prototype** `void *BmpGetBits (BitmapType *bitmapP)`
- Parameters** `-> bitmapP` Pointer to the bitmap's structure. (See [BitmapType](#).)
- Result** Returns a pointer to the bitmap's data.
- Comments** This function returns the bitmap's data even if the bitmap's indirect flag is set. (See [BitmapFlagsType](#).)
- Compatibility** Implemented only if [3.5 New Feature Set](#) is present.
- See Also** [BmpBitsSize](#)

## BmpGetBitDepth

- Purpose** Retrieve the depth of a bitmap.
- Declared In** `Bitmap.h`
- Prototype** `UInt8 BmpGetBitDepth (const BitmapType* bitmapP)`
- Parameters** `-> bitmapP` Pointer to a bitmap. See [BitmapType](#).
- Result** This function returns the bit depth of the bitmap, as represented by the `pixelSize` field in [BitmapType](#). For debug ROMs, this function reports an error and returns 0 if `bitmapP` is NULL.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS,

## Bitmaps

### Bitmap Functions

---

link with the PalmOSGlue library and call `BmpGlueGetBitDepth`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [BmpGetDimensions](#), [BmpGetNextBitmap](#), [BmpGetSizes](#)

## BmpGetColortable

**Purpose** Retrieve the bitmap’s color table.

**Declared In** `Bitmap.h`

**Prototype** `ColorTableType *BmpGetColortable  
(BitmapType *bitmapP)`

**Parameters** `-> bitmapP` A pointer to the bitmap. See [BitmapType](#).

**Result** Returns a pointer to the color table or `NULL` if the bitmap uses the system color table.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [BmpColortableSize](#)

---

## New BmpGetCompressionType

**Purpose** Get the compression type of a bitmap.

**Declared In** `Bitmap.h`

**Prototype** `BitmapCompressionType BmpGetCompressionType  
(const BitmapType *bitmapP)`

**Parameters** `-> bitmapP` Pointer to a valid bitmap. See [BitmapType](#).

**Result** Returns the type of compression used by `bitmapP`. See [“BitmapCompressionType”](#) on page 513 for the values that can be

returned from this function. For debug ROMs, this function reports an error and returns `BitmapCompressionTypeNone` if `bitmapP` is `NULL`.

**Comments** If the bitmap is not compressed, this function returns `BitmapCompressionTypeNone`. If the bitmap version is 0 or 1 (corresponding to [BitmapTypeV0](#) and [BitmapTypeV1](#), respectively), it returns `BitmapCompressionTypeScanLine`.

**Compatibility** Implemented only if either the [5.0 New Feature Set](#) or the [High-Density Display Feature Set](#) is present.

**See Also** [BmpCompress](#)

---

## **New** **BmpGetDensity**

**Purpose** Get the density of a bitmap.

**Declared In** `Bitmap.h`

**Prototype** `UInt16 BmpGetDensity (const BitmapType *bitmapP)`

**Parameters** `-> bitmapP` Pointer to a valid bitmap. See [BitmapType](#).

**Result** Returns the density of `bitmapP`; see the [DensityType](#) enum for the defined set of density values. For debug ROMs, this function reports an error and returns 0 if `bitmapP` is `NULL`.

**Comments** Note that bitmaps with a version of 0, 1, or 2 (corresponding to [BitmapTypeV0](#), [BitmapTypeV1](#), and [BitmapTypeV2](#), respectively) are assumed to be low density (`kDensityLow`).

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also** [BmpCreateBitmapV3](#), [BmpSetDensity](#)

## Bitmaps

### Bitmap Functions

---

## BmpGetDimensions

- Purpose** Retrieve the width, height and number of data bytes per row of a bitmap.
- Declared In** `Bitmap.h`
- Prototype** `void BmpGetDimensions (const BitmapType *bitmapP, Coord *widthP, Coord *heightP, UInt16 *rowBytesP)`
- Parameters**
- `-> bitmapP` Pointer to the bitmap. See [BitmapType](#).
  - `<- widthP` Pointer to bitmap's width in pixels. Use NULL if this information is not wanted.
  - `<- heightP` Pointer to bitmap's height in pixels. Use NULL if this information is not wanted. Use NULL if this information is not wanted.
  - `<- rowBytesP` Pointer to number of bytes per row of bitmap. Use NULL if this information is not wanted.
- Result** This function returns the width in pixels of the bitmap in `widthP`, the height in pixels of the bitmap in `heightP`, and the number of bytes of data per row of the bitmap in `rowBytesP`. This function reports an error on debug ROMs if `bitmapP` is NULL.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `BmpGlueGetDimensions`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)
- See Also** [BmpGetBitDepth](#), [BmpGetNextBitmap](#), [BmpGetSizes](#)

## **BmpGetNextBitmap**

- Purpose** Retrieve the next low-density bitmap in a bitmap family.
- Declared In** `Bitmap.h`
- Prototype** `BitmapType *BmpGetNextBitmap(BitmapType *bitmapP)`
- Parameters** `-> bitmapP` Pointer to a bitmap. See [BitmapType](#).
- Result** This function returns a pointer to the next low-density [BitmapType](#) in a bitmap family. It returns NULL if `bitmapP` is the last bitmap. For debug ROMs, this function reports an error and returns 0 if `bitmapP` is NULL.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `BmpGlueGetNextBitmap`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)
- See Also** [BmpGetBitDepth](#), [BmpGetDimensions](#), [BmpGetNextBitmapAnyDensity](#), [BmpGetSizes](#)

## Bitmaps

### Bitmap Functions

---

## **New** **BmpGetNextBitmapAnyDensity**

- Purpose** Get the next bitmap in the bitmap family, irrespective of density.
- Declared In** `Bitmap.h`
- Prototype** `BitmapType *BmpGetNextBitmapAnyDensity  
(BitmapType *bitmapP)`
- Parameters** `-> bitmapP` Pointer to a valid bitmap. See [BitmapType](#).
- Result** Returns the next bitmap in a bitmap family, or NULL if `bitmapP` is the last bitmap. For debug ROMs, this function reports an error and returns 0 if `bitmapP` is NULL.
- Comments** This function is an extended version of [BmpGetNextBitmap](#). For backward compatibility, `BmpGetNextBitmap` only returns low-density bitmaps. If the bitmap family contains high-density bitmaps, however, `BitmapGetNextBitmapAnyDensity` skips over the dummy bitmap that separates the low and high-density bitmaps in the linked list and returns a high-density bitmap.
- Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.
- See Also** [BmpGetDensity](#), [BmpGetNextBitmap](#)

## BmpGetSizes

<b>Purpose</b>	Retrieve the size of a bitmap and its header structure.						
<b>Declared In</b>	<code>Bitmap.h</code>						
<b>Prototype</b>	<code>void BmpGetSizes (const BitmapType *bitmapP, UInt32 *dataSizeP, UInt32 *headerSizeP)</code>						
<b>Parameters</b>	<table><tr><td><code>-&gt;bitmapP</code></td><td>Pointer to the bitmap. See <a href="#">BitmapType</a>.</td></tr><tr><td><code>&lt;-dataSizeP</code></td><td>Pointer to size of bitmap data, not including structures. Use NULL if this information is not wanted.</td></tr><tr><td><code>&lt;-headerSizeP</code></td><td>Pointer to size of bitmap's structures, not including data. Use NULL if this information is not wanted.</td></tr></table>	<code>-&gt;bitmapP</code>	Pointer to the bitmap. See <a href="#">BitmapType</a> .	<code>&lt;-dataSizeP</code>	Pointer to size of bitmap data, not including structures. Use NULL if this information is not wanted.	<code>&lt;-headerSizeP</code>	Pointer to size of bitmap's structures, not including data. Use NULL if this information is not wanted.
<code>-&gt;bitmapP</code>	Pointer to the bitmap. See <a href="#">BitmapType</a> .						
<code>&lt;-dataSizeP</code>	Pointer to size of bitmap data, not including structures. Use NULL if this information is not wanted.						
<code>&lt;-headerSizeP</code>	Pointer to size of bitmap's structures, not including data. Use NULL if this information is not wanted.						
<b>Result</b>	Returns the size of the bitmap and the size of the bitmap's structures. This function will report an error on debug ROMs if <code>bitmapP</code> is NULL.						
<b>Comments</b>	<p>This function returns the size in bytes of the bitmap data in <code>dataSizeP</code>. The size does not include the data structures (<a href="#">BitmapType</a>, <a href="#">BitmapDirectInfoType</a>, or color table) that are associated with a bitmap. The size of the structures (in bytes) are returned in <code>headerSizeP</code>, which includes the size of the <a href="#">BitmapType</a>, <a href="#">BitmapDirectInfoType</a> (if any), the color table (if any), and the size of the pointer for indirect bitmaps (described in <a href="#">BitmapFlagsType</a>).</p> <p>This function should be used when working with bitmaps that may be 64 Kb or greater. Do not use <a href="#">BmpSize</a> or <a href="#">BmpBitsSize</a> when working with bitmaps that may be greater than or equal to 64Kb.</p>						
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present.						
<b>See Also</b>	<a href="#">BmpGetBitDepth</a> , <a href="#">BmpGetDimensions</a> , <a href="#">BmpGetNextBitmap</a>						

## Bitmaps

### Bitmap Functions

---

## New **BmpGetTransparentValue**

---

**Purpose** Get a bitmap's transparent color.

**Declared In** `Bitmap.h`

**Prototype** `Boolean BmpGetTransparentValue  
(const BitmapType *bitmapP,  
UInt32 *transparentValueP)`

**Parameters**

- > `bitmapP` Pointer to a valid bitmap. See [BitmapType](#).
- <- `transparentValueP` Pointer to a variable that receives the transparent color, either as a palette index or as a direct color value (an [RGBColorType](#)), depending on the bitmap's depth.

**Result** Returns `true` if `bitmapP` has a transparent color defined, `false` otherwise.

**Compatibility** Implemented only if either the [5.0 New Feature Set](#) or the [High-Density Display Feature Set](#) is present.

**See Also** [BmpSetTransparentValue](#)

---

## **New** **BmpGetVersion**

- Purpose** Get the version of a bitmap.
- Declared In** `Bitmap.h`
- Prototype** `UInt8 BmpGetVersion (const BitmapType *bitmapP)`
- Parameters** `-> bitmapP` Pointer to a valid bitmap. See [BitmapType](#).
- Result** Returns the version of `bitmapP`. See “[Bitmap Constants](#)” on page 535 for the defined bitmap version numbers. For debug ROMs, this function reports an error and returns 0 if `bitmapP` is NULL.
- Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

---

## **New** **BmpSetDensity**

- Purpose** Set the density of a version 3 bitmap.
- Declared In** `Bitmap.h`
- Prototype** `Err BmpSetDensity (BitmapType *bitmapP, UInt16 density)`
- Parameters** `-> bitmapP` Pointer to a valid version 3 bitmap. See [BitmapTypeV3](#).

## Bitmaps

### Bitmap Functions

---

-> density      The bitmap's density. This value should be one of the values defined by the [DensityType](#) enum.

**Result**      Returns `errNone` if the operation completed successfully, or `SysErrParamErr` either if `bitmapP` is `NULL`, if `density` is not supported by the blitter, or if `*bitmapP` is not a version 3 bitmap.

**Comments**      To allocate a high-density bitmap, first call [BmpCreateBitmapV3](#). Then call [BmpSetDensity](#) to specify the bitmap's density.

**Compatibility**      Implemented only if the [High-Density Display Feature Set](#) is present.

**See Also**      [BmpGetDensity](#)

---

## New **BmpSetTransparentColor**

**Purpose**      Set a bitmap's transparent color.

**Declared In**      `Bitmap.h`

**Prototype**      `void BmpSetTransparentColor (BitmapType *bitmapP, UInt32 transparentValue)`

**Parameters**      -> `bitmapP`      Pointer to a valid bitmap. See [BitmapType](#).  
-> `transparentValue`      Transparent color. This should either be a palette index or a direct color value (an [RGBColorType](#)), depending on the bitmap's depth.

**Result**      Returns nothing.

**Comments**      If `bitmapP` points to a version 2 bitmap, [BmpSetTransparentColor](#) sets the [BitmapTypeV2](#) structure's

hasTransparency flag to true and initializes the structure's transparentIndex field according to transparentValue. For 16-bit bitmaps, this function sets the transparentColor field in the BitmapDirectInfoType auxiliary structure and sets the transparentIndex field to 0.

If bitmapP points to a version 3 bitmap, BmpSetTransparentValue sets the [BitmapTypeV3](#) structure's hasTransparency flag to true and sets the transparentValue field to the transparent color.

Regardless of the bitmap version, if this function is passed a transparentValue set to kTransparencyNone, this function sets the bitmap structure's hasTransparency flag to false and sets the transparent color field(s) to 0.

This function does nothing if transparentValue contains a value that is not valid for the depth of bitmapP.

**Compatibility** Implemented only if either the [5.0 New Feature Set](#) or the [High-Density Display Feature Set](#) is present.

**See Also** [BmpGetTransparentValue](#)

## BmpSize

**Purpose** Return the size of the bitmap.

**Declared In** `Bitmap.h`

**Prototype** `UInt16 BmpSize (const BitmapType *bitmapP)`

**Parameters** `-> bitmapP` A pointer to the bitmap. See [BitmapType](#).

**Result** Returns the size in bytes of the bitmap, including its header, color table (if any), and `sizeof (BitmapDirectInfoType)` if one exists.

**Comments** If the bitmap has its indirect flag set (see [BitmapFlagsType](#)), the bitmap data is not included in the size returned by this function.

## Bitmaps

### Bitmap Functions

---

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [BmpBitsSize](#), [BmpColortableSize](#)

## ColorTableEntries

**Purpose** Macro that returns the color table.

**Declared In** `Bitmap.h`

**Prototype** `ColorTableEntries (ctP)`

**Parameters** `-> ctP` A pointer to a [ColorTableType](#) structure.

**Result** Returns an array of [RGBColorType](#) structures, one for each entry in the color table.

**Comments** You can use this macro to retrieve the RGB values in use by a bitmap. For example:

```
BitmapType *bmpP;  
RGBColorType *tableP =  
    ColorTableEntries (BmpGetColorTable (bmpP) );
```

If you want to retrieve the RGB values in use by the system color table, you can simply use the [WinPalette](#) function instead of this macro:

```
RGBColorType table[256];  
Err e;  
  
/* allocate space for table */  
e = WinPalette(winPaletteGet, 0, 256, tableP);
```

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [BmpGetColortable](#)

# Character Attributes

---

This chapter provides reference material for character attributes functions defined in `CharAttr.h`.

## Character Attribute Functions

### ChrHorizEllipsis

<b>Purpose</b>	Macro that returns the appropriate character code for the horizontal ellipsis.
<b>Declared In</b>	<code>Chars.h</code>
<b>Prototype</b>	<code>ChrHorizEllipsis (chP)</code>
<b>Parameters</b>	<code>&lt;- chP</code> Pointer to a variable in which to return the horizontal ellipsis character code.
<b>Result</b>	Returns nothing. Upon return, the variable pointed to by <code>chP</code> contains the horizontal ellipsis character.
<b>Comments</b>	Version 3.1 of the Palm OS <sup>®</sup> uses different character codes for the horizontal ellipsis character and the numeric space character than earlier versions did. Use this macro to return the appropriate code for horizontal ellipsis regardless of which version of Palm OS your application is run on.

## Character Attributes

### Character Attribute Functions

---

#### ChrisHardKey

<b>Purpose</b>	Macro that returns true if the character is one of the hard keys on the device.
<b>Declared In</b>	<code>Chars.h</code>
<b>Prototype</b>	<code>ChrIsHardKey (ch)</code>
<b>Parameters</b>	-> <code>ch</code> The character from the <code>keyDownEvent</code> .
<b>Result</b>	<code>true</code> if the character is one of the four built-in hard keys on the device, <code>false</code> otherwise.
<b>Compatibility</b>	This macro is obsolete and replaced by <a href="#">TxtCharIsHardKey</a> if the <a href="#">International Feature Set</a> is present.

#### ChrNumericSpace

<b>Purpose</b>	Macro that returns the appropriate character code for the numeric space.
<b>Declared In</b>	<code>Chars.h</code>
<b>Prototype</b>	<code>ChrNumericSpace (chP)</code>
<b>Parameters</b>	<- <code>chP</code> Pointer to a variable in which to return the numeric space character code.
<b>Result</b>	Returns nothing. Upon return, the variable pointed to by <code>chP</code> contains the numeric space character.
<b>Comments</b>	Version 3.1 of the Palm OS uses different character codes for the horizontal ellipsis character and the numeric space character than earlier versions did. Use this macro to return the appropriate code for numeric space regardless of which version of Palm OS your application is run on.

## GetCharAttr

<b>Purpose</b>	Return a pointer to the character attribute array. This array is used by the character classification and character conversion macros (such as <code>isalpha</code> ).
<b>Declared In</b>	<code>CharAttr.h</code>
<b>Prototype</b>	<code>UInt16* GetCharAttr (void)</code>
<b>Parameters</b>	None
<b>Result</b>	A pointer to the attributes array. This is an array of 256 <code>UInt16</code> values, one for each possible character code. See <code>CharAttr.h</code> for an explanation of the attributes.
<b>Compatibility</b>	This function is <b>not</b> implemented if <a href="#">International Feature Set</a> is present.
<hr/> <b>NOTE:</b> This function is provided for backwards compatibility only. Use <a href="#">Text Manager</a> functions instead on systems that support the text manager. <hr/>	
If <a href="#">5.0 New Feature Set</a> is present, this function is implemented in PACE. However, it only supports the Latin table, regardless of the localization.	
<b>See Also</b>	<a href="#">TxtCharAttr</a> , <a href="#">TxtCharXAttr</a>

## Character Attributes

### Character Attribute Functions

---

## GetCharCaselessValue

<b>Purpose</b>	Return a pointer to an array that maps all characters to an assigned caseless and accentless value. Use this function for finding text.
<b>Declared In</b>	CharAttr.h
<b>Prototype</b>	UInt8* GetCharCaselessValue (void)
<b>Parameters</b>	None.
<b>Result</b>	Returns a pointer to the sort array, which is an array of 256 bytes.
<b>Comment</b>	<p>The <code>GetCharCaselessValue</code> conversion table converts each character into a numeric value that is caseless and sorted according to Microsoft Windows sorting rules:</p> <ul style="list-style-type: none"><li>• Punctuation characters have the lowest values,</li><li>• followed by numbers,</li><li>• followed by alpha characters.</li></ul> <p>All forms of each alpha character have equivalent values, so that e = E = e-grave = e-circumflex, etc.</p> <p>This conversion table is used by all the Palm OS sorting and comparison routines to yield caseless searches and caseless sorts in the almost same order as Windows-based programs, except that Palm OS routines produce the same sorting for all locales.</p>
<b>Compatibility</b>	This function is <b>not</b> implemented if <a href="#">International Feature Set</a> is present.

---

**NOTE:** This function is provided for backwards compatibility only. Use [Text Manager](#) functions instead on systems that support the text manager.

---

If [5.0 New Feature Set](#) is present, this function is implemented in PACE. However, it only supports the Latin table, regardless of the localization.

## GetCharSortValue

<b>Purpose</b>	Return a pointer to an array that maps all characters to an assigned sorting value. Use this function for ordering (sorting) text.
<b>Declared In</b>	CharAttr.h
<b>Prototype</b>	UInt8* GetCharSortValue (void)
<b>Parameters</b>	None.
<b>Result</b>	Returns a pointer to the attributes array. This is an array of 256 UInt8 values, one for each possible character code.
<b>Compatibility</b>	This function is <b>not</b> implemented if <a href="#">International Feature Set</a> is present.

---

**NOTE:** This function is provided for backwards compatibility only. Use [Text Manager](#) functions instead on systems that support the text manager.

---

If [5.0 New Feature Set](#) is present, this function is implemented in PACE. However, it only supports the Latin table, regardless of the localization.

# Data and Resource Manager

---

This chapter describes the data manager and the resource manager API declared in the header file `DataMgr.h`. It discusses the following topics:

- [Data Manager Data Structures](#)
- [Data Manager Constants](#)
- [Data Manager Functions](#)
- [Application-Defined Functions](#)

For more information on the data and resource managers, see the chapter “[Files and Databases](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Data Manager Data Structures

### DmOpenRef

The `DmOpenRef` type defines a pointer to an open database. The database pointer is created and returned by [DmOpenDatabase](#). It is used in any function that requires access to an open database.

```
typedef void *DmOpenRef
```

### DmResID

The `DmResID` type defines a resource identifier. You assign each resource an ID at creation time. Note that resource IDs greater than or equal to 10000 are reserved for system use.

## Data and Resource Manager

### Data Manager Constants

---

```
typedef UInt16 DmResID;
```

### DmResType

The `DmResType` type defines the type of a resource. The resource type is a four-character code such as 'Tbmp' for bitmap resources.

```
typedef UInt32 DmResType;
```

### SortRecordInfoType

The `SortRecordInfoType` structure specifies information that can be used to sort a record. The database sorting functions ([DmInsertionSort](#) and [DmQuickSort](#)) pass this structure to your comparison callback function (of type [DmComparF](#)), where you can use the information therein to help when comparing two records. To create this structure, you can call [DmRecordInfo](#), which returns these values for a given record.

```
typedef struct {
    UInt8 attributes;
    UInt8 uniqueID[3];
} SortRecordInfoType;
```

```
typedef SortRecordInfoType *SortRecordInfoPtr;
```

#### Field Descriptions

`attributes` The record's attributes. See "[Record Attribute Constants](#)."

`uniqueID` The unique identifier for the record.

## Data Manager Constants

### Category Constants

The following constants are used to specify information about categories:

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>dmAllCategories</code>	0xFF	A mask used to represent all categories.
<code>dmCategoryLength</code>	16	The length of a category name. Currently, this is 16 bytes, which includes the null terminator.
<code>dmRecAttrCategoryMask</code>	0x0F	A mask used to retrieve the category information from the record's attributes field.
<code>dmRecNumCategories</code>	16	The number of categories allowed. Currently, this is 16, which includes the "Unfiled" category.
<code>dmUnfiledCategory</code>	0	A mask used to indicate the Unfiled category.

### **Record Attribute Constants**

The following constants specify a database record's attributes.

<b>Constant</b>	<b>Value</b>	<b>Description</b>
<code>dmMaxRecordIndex</code>	0xFFFF	Indicates the highest record index allowed.
<code>dmAllRecAttrs</code>	0xF0	A mask used to specify all record attributes.
<code>dmRecAttrBusy</code>	0x20	Busy (the application has locked access to this record). A call to <a href="#">DmGetRecord</a> fails on a record that has this bit set, otherwise it sets this bit. Call <a href="#">DmReleaseRecord</a> to release the record and clear this bit. The <a href="#">DmSetRecordInfo</a> function cannot be used to alter the state of <code>dmRecAttrBusy</code> .
<code>dmRecAttrDelete</code>	0x80	Deleted
<code>dmRecAttrDirty</code>	0x40	Dirty (has been modified since last sync)
<code>dmRecAttrSecret</code>	0x10	Private
<code>dmSysOnlyRecAttrs</code>	0x20	A mask used to specify record attributes that only the system can change. (In other words, the busy attribute.)

## **Data and Resource Manager**

### *Data Manager Constants*

---

## Database Attribute Constants

The following constants define a database's attributes:

Constant	Description
<code>dmAllHdrAttrs</code>	A mask used to specify all header attributes.
<code>dmHdrAttrAppInfoDirty</code>	The application info block is dirty (has been modified since the last sync).
<code>dmHdrAttrBackup</code>	The database should be backed up to the desktop computer if no application-specific conduit is available.
<code>dmHdrAttrBundle</code>	<p>The database is bundled with its application during a beam. That is, if the user chooses to beam the application from the Launcher, the Launcher beams this database along with the application's resource database and overlay database.</p> <p>This attribute applies to Palm OS<sup>®</sup> 4.0 and higher. Note that overlay databases are automatically beamed with the application database on Palm OS 4.0 and higher. You do not need to set this bit in overlay databases.</p>
<code>dmHdrAttrCopyPrevention</code>	Prevents the database from being copied by methods such as IR beaming.
<code>dmHdrAttrHidden</code>	<p>This database should be hidden from view. For example, this attribute is set to hide some applications in the launcher's main view. You can set it on record databases to have the launcher disregard the database's records when showing a count of records.</p> <p>This attribute applies to Palm OS version 3.2 and higher.</p>

## Data and Resource Manager

### Data Manager Constants

---

Constant	Description
<code>dmHdrAttrLaunchableData</code>	This database is a data database but it can be “launched” from the launcher. For example, this attribute is set in Palm Query Applications (PQAs) launched by the Web Clipping Application Viewer application.
<code>dmHdrAttrOpen</code>	The database is open.
<code>dmHdrAttrOKToInstallNewer</code>	The backup conduit can install a newer version of this database with a different name if the current database is open. This mechanism is used to update the Graffiti® Shortcuts database, for example.
<code>dmHdrAttrReadOnly</code>	The database is a read-only database.
<code>dmHdrAttrRecyclable</code>	The database is recyclable. Recyclable databases are deleted when they are closed or upon a system reset.  This attribute applies to Palm OS 4.0 and higher.
<code>dmHdrAttrResDB</code>	The database is a resource database.
<code>dmHdrAttrResetAfterInstall</code>	The device must be reset after this database is installed. That is, the HotSync® application forces a reset after installing this database.
<code>dmHdrAttrStream</code>	The database is a file stream.
<code>dmSysOnlyHdrAttrs</code>	A mask specifying the attributes that only the system can change (open and resource database).

---

## Error Codes

The following constants define error codes that are returned by the data manager and resource manager functions. Several functions return a failure value such as `NULL` or `0` instead of an error code. In many cases, you can call [DmGetLastError](#) upon receiving this value and receive a more descriptive error code.

Also, note that on releases prior to Palm OS release 3.5, many data manager functions display a fatal error message using the [ErrFatalDisplayIf](#) macro if certain error conditions are true. Because the Palm OS ROMs are usually shipped with error checking set to partial, you receive the fatal error message. If a ROM is built with error checking set to none, the function returns one of the error codes listed here. (Note that Palm™ has never released a ROM with error checking set to none and has no plans to do so.)

---

Constant	Description
<code>dmErrAlreadyExists</code>	Another database with the same name already exists in RAM store.
<code>dmErrAlreadyOpenForWrites</code>	The database is already open with write access.
<code>dmErrCantFind</code>	The specified resource can't be found.
<code>dmErrCantOpen</code>	The database cannot be opened.
<code>dmErrCorruptDatabase</code>	The database is corrupted.
<code>dmErrDatabaseOpen</code>	The function cannot be performed on an open database, and the database is open.
<code>dmErrDatabaseNotProtected</code>	<a href="#">DmDatabaseProtect</a> failed to protect the specified database.
<code>dmErrIndexOutOfRange</code>	The specified index is out of range.
<code>dmErrInvalidDatabaseName</code>	The name you've specified for the database is invalid.
<code>dmErrInvalidParam</code>	The function received an invalid parameter.
<code>dmErrMemError</code>	A memory error occurred.

---

## Data and Resource Manager

### Data Manager Constants

---

Constant	Description
<code>dmErrNoOpenDatabase</code>	The function is to search all open databases, but there are none.
<code>dmErrNotRecordDB</code>	You've attempted to perform a record function on a resource database.
<code>dmErrNotResourceDB</code>	You've attempted to perform a resource manager function on a record database.
<code>dmErrNotValidRecord</code>	The record handle is invalid.
<code>dmErrOpenedByAnotherTask</code>	You've attempted to open a database that another task already has open.
<code>dmErrReadOnly</code>	You've attempted to write to or modify a database that is in read-only mode.
<code>dmErrRecordArchived</code>	The function requires that the record not be archived, but it is.
<code>dmErrRecordBusy</code>	The function requires that the record not be busy, but it is.
<code>dmErrRecordDeleted</code>	The record has been deleted.
<code>dmErrRecordInWrongCard</code>	You've attempted to attach a record to a database when the record and database reside on different memory cards.

<b>Constant</b>	<b>Description</b>
<code>dmErrResourceNotFound</code>	The resource can't be found.
<code>dmErrROMBased</code>	You've attempted to delete or modify a ROM-based database.
<code>dmErrSeekFailed</code>	The operation of seeking the next record in the category failed.
<code>dmErrUniqueIDNotFound</code>	A record with the specified unique ID can't be found.
<code>dmErrWriteOutOfBounds</code>	A write operation exceeded the bounds of the record.
<code>memErrCardNotPresent</code>	The specified card can't be found.
<code>memErrChunkLocked</code>	The associated memory chunk is locked.
<code>memErrInvalidParam</code> <code>memErrNotEnoughSpace</code>	A memory error occurred.
<code>memErrInvalidStoreHeader</code> <code>memErrRAMOnlyCard</code>	The specified card has no storage RAM.
<code>omErrBaseRequiresOverlay</code>	An attempt was made to open a stripped resource database, but no associated overlay could be found.
<code>omErrUnknownLocale</code>	An attempt was made to open a resource database with overlays using an unknown locale.

---

## Data and Resource Manager

### Data Manager Constants

---

### Open Mode Constants

The following constants define the mode in which a database can be opened. You pass one or more of these as a parameter to [DmOpenDatabase](#), [DmOpenDatabaseByTypeCreator](#), or [DmOpenDBNoOverlay](#):

Constant	Description
<code>dmModeReadWrite</code>	Read-write access.
<code>dmModeReadOnly</code>	Read-only access.
<code>dmModeWrite</code>	Write-only access.
<code>dmModeLeaveOpen</code>	Leave database open even after application quits.
<code>dmModeExclusive</code>	Don't let anyone else open this database.
<code>dmModeShowSecret</code>	Show records marked private.

### Miscellaneous Constants

The following additional constants are used in conjunction with the Data Manager.

Constant	Value	Description
<code>dmDBNameLength</code>	32	Maximum length of a database name, including the null terminator. Database names must use only 7-bit ASCII characters (0x20 through 0x7E).

## Data Manager Functions

### DmArchiveRecord

<b>Purpose</b>	Mark a record as archived by leaving the record's chunk intact and setting the delete bit for the next sync.
<b>Declared In</b>	DataMgr.h
<b>Prototype</b>	Err DmArchiveRecord (DmOpenRef dbP, UInt16 index)
<b>Parameters</b>	-> dbP                   DmOpenRef to open database. -> index                 Which record to archive.
<b>Result</b>	Returns errNone if no error, or one of the following if an error occurs: <ul style="list-style-type: none"><li>• <a href="#">dmErrReadOnly</a></li><li>• <a href="#">dmErrIndexOutOfRange</a></li><li>• <a href="#">dmErrRecordArchived</a></li><li>• <a href="#">dmErrRecordDeleted</a></li><li>• <a href="#">memErrInvalidParam</a></li></ul> Some releases may display a fatal error message instead of returning the error code.
<b>Comments</b>	When a record is archived, the deleted bit is set but the chunk is not freed and the local ID is preserved. This way, the next time the user synchronizes with the desktop system, the desktop can save the record data on the PC before it permanently removes the record entry and data from the Palm Powered™ device.  Based on the assumption that a call to DmArchiveRecord indicates that you are finished with the record and aren't going to refer to it again, this function sets the chunk's lock count to zero.
<b>See Also</b>	<a href="#">DmRemoveRecord</a> , <a href="#">DmDetachRecord</a> , <a href="#">DmNewRecord</a> , <a href="#">DmDeleteRecord</a>

## DmAttachRecord

<b>Purpose</b>	Attach an existing chunk ID handle to a database as a record.								
<b>Declared In</b>	DataMgr.h								
<b>Prototype</b>	<pre>Err DmAttachRecord (DmOpenRef dbP, UInt16 *atP, MemHandle newH, MemHandle *oldHP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; dbP</td><td>DmOpenRef to open database.</td></tr><tr><td>&lt;-&gt; atP</td><td>Pointer to the index where the new record should be placed. Specify the value dmMaxRecordIndex to add the record to the end of the database.</td></tr><tr><td>-&gt; newH</td><td>Handle of the new record.</td></tr><tr><td>&lt;-&gt; oldHP</td><td>If non-NULL upon entry, indicates that the record at *atP should be replaced. Upon return, contains the handle to the replaced record.</td></tr></table>	-> dbP	DmOpenRef to open database.	<-> atP	Pointer to the index where the new record should be placed. Specify the value dmMaxRecordIndex to add the record to the end of the database.	-> newH	Handle of the new record.	<-> oldHP	If non-NULL upon entry, indicates that the record at *atP should be replaced. Upon return, contains the handle to the replaced record.
-> dbP	DmOpenRef to open database.								
<-> atP	Pointer to the index where the new record should be placed. Specify the value dmMaxRecordIndex to add the record to the end of the database.								
-> newH	Handle of the new record.								
<-> oldHP	If non-NULL upon entry, indicates that the record at *atP should be replaced. Upon return, contains the handle to the replaced record.								
<b>Result</b>	Returns errNone if no error, or one of the following if an error occurs: <ul style="list-style-type: none"><li>• <a href="#">dmErrMemError</a></li><li>• <a href="#">memErrChunkLocked</a></li><li>• <a href="#">memErrInvalidParam</a></li><li>• <a href="#">memErrNotEnoughSpace</a></li><li>• <a href="#">dmErrReadOnly</a></li><li>• <a href="#">dmErrNotRecordDB</a></li><li>• <a href="#">dmErrRecordInWrongCard</a></li><li>• <a href="#">dmErrIndexOutOfRange</a></li></ul> Some releases may display a fatal error message instead of returning some of these error codes.								
<b>Comments</b>	Given the handle of an existing chunk, this routine makes that chunk a new record in a database and sets the dirty bit. The								

parameter `atP` points to an index variable. If `oldHP` is `NULL`, the new record is inserted at index `*atP` and all record indices that follow are shifted down. If `*atP` is greater than the number of records currently in the database, the new record is appended to the end and its index is returned in `*atP`. If `oldHP` is not `NULL`, the new record replaces an existing record at index `*atP` and the handle of the old record is returned in `*oldHP` so that the application can free it or attach it to another database.

This function is useful for cutting and pasting between databases.

**See Also** [DmDetachRecord](#), [DmNewRecord](#), [DmNewHandle](#), [DmFindSortPosition](#)

## **DmAttachResource**

**Purpose** Attach an existing chunk ID to a resource database as a new resource.

**Declared In** `DataMgr.h`

**Prototype** `Err DmAttachResource (DmOpenRef dbP, MemHandle newH, DmResType resType, DmResID resID)`

**Parameters**

-> <code>dbP</code>	DmOpenRef to open database.
-> <code>newH</code>	Handle of new resource's data.
-> <code>resType</code>	Type of the new resource.
-> <code>resID</code>	ID of the new resource.

**Result** Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrMemError](#)
- [memErrChunkLocked](#)
- [memErrInvalidParam](#)
- [memErrNotEnoughSpace](#)
- [dmErrReadOnly](#)

## Data and Resource Manager

### Data Manager Functions

---

- [dmErrRecordInWrongCard](#)

Some releases may display a fatal error message instead of returning some of these error codes. All releases may display a fatal error message if the database is not a resource database.

**Comments** Given the handle of an existing chunk with resource data in it, this routine makes that chunk a new resource in a resource database. The new resource will have the given type and ID.

**See Also** [DmDetachResource](#), [DmRemoveResource](#), [DmNewHandle](#), [DmNewResource](#)

## DmCloseDatabase

**Purpose** Close a database.

**Declared In** `DataMgr.h`

**Prototype** `Err DmCloseDatabase (DmOpenRef dbP)`

**Parameters** `-> dbP` Database access pointer.

**Result** Returns `errNone` if no error, or [dmErrInvalidParam](#) if an error occurs. Some releases may display a fatal error message instead of returning the error code.

**Comments** This routine doesn't unlock any records that were left locked. Records and resources should not be left locked. If a record/resource is left locked, you should not use its reference because the record can disappear during a HotSync operation or if the database is deleted by the user. To prevent the database from being deleted, you can use [DmDatabaseProtect](#) before closing.

If there is an overlay associated with the database passed in, `DmCloseDatabase` closes the overlay as well.

If the database has the recyclable bit set (`dmHdrAttrRecyclable`), `DmCloseDatabase` calls [DmDeleteDatabase](#) to delete it.

- Compatibility** Starting with Palm OS 2.0, `DmCloseDatabase` updates the database's modification date.
- On Palm OS 2.0, the modification date is updated if the database was opened with write access.
  - On Palm OS 3.0 and higher, the modification date is updated only if a change has been made and the database was opened with write access. Changes that trigger an update include adding, deleting, archiving, rearranging, or resizing records, setting a record's dirty bit in [DmReleaseRecord](#), rearranging or deleting categories, or updating the database header fields using [DmSetDatabaseInfo](#).

Under Palm OS 1.0, the modification date was never updated.

If you need to ensure that the modification date is updated the same way regardless of the operating system version, use [DmSetDatabaseInfo](#) to set the modification date explicitly.

**See Also** [DmOpenDatabase](#), [DmDeleteDatabase](#),  
[DmOpenDatabaseByTypeCreator](#)

## DmCreateDatabase

**Purpose** Create a new database on the specified card with the given name, creator, and type.

**Declared In** `DataMgr.h`

**Prototype** `Err DmCreateDatabase (UInt16 cardNo,  
const Char *nameP, UInt32 creator, UInt32 type,  
Boolean resDB)`

**Parameters**

-> cardNo	The card number to create the database on.
-> nameP	Name of new database, up to 32 ASCII bytes long, including the null terminator (as specified by <code>dmDBNameLength</code> ). Database names must use only 7-bit ASCII characters (0x20 through 0x7E).
-> creator	Creator of the database.

## Data and Resource Manager

### Data Manager Functions

---

- > type                   Type of the database.
- > resDB                   If true, create a resource database.

**Result** Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrInvalidDatabaseName](#)
- [dmErrAlreadyExists](#)
- [memErrCardNotPresent](#)
- [dmErrMemError](#)
- [memErrChunkLocked](#)
- [memErrInvalidParam](#)
- [memErrInvalidStoreHeader](#)
- [memErrNotEnoughSpace](#)
- [memErrRAMOnlyCard](#)

May display a fatal error message if the master database list cannot be found.

**Comments** Call this routine to create a new database on a specific card. If another database with the same name already exists in RAM store, this routine returns a [dmErrAlreadyExists](#) error code. Once created, the database ID can be retrieved by calling [DmFindDatabase](#). The database can be opened using the database ID. To create a resource database instead of a record-based database, set the `resDB` Boolean to `true`.

After you create a database, it's recommended that you call [DmSetDatabaseInfo](#) to set the version number. Databases default to version 0 if the version isn't explicitly set.

**See Also** [DmCreateDatabaseFromImage](#), [DmOpenDatabase](#), [DmDeleteDatabase](#)

## **DmCreateDatabaseFromImage**

- Purpose** Create an entire database from a single resource that contains an image of the database.
- Declared In** `DataMgr.h`
- Prototype** `Err DmCreateDatabaseFromImage (MemPtr bufferP)`
- Parameters** `-> bufferP` Pointer to locked resource containing database image.
- Result** Returns `errNone` if no error.
- Comments** An image is the same as a desktop file representation of a `prc` or `pdb` file.  
  
This function is intended for applications in the ROM to install default databases after a hard reset. RAM-based applications that want to install a default database should install a `pdb` file separately to save storage heap space.
- See Also** [DmCreateDatabase](#), [DmOpenDatabase](#)

## **DmDatabaseInfo**

- Purpose** Retrieve information about a database.
- Declared In** `DataMgr.h`
- Prototype** `Err DmDatabaseInfo (UInt16 cardNo, LocalID dbID, Char *nameP, UInt16 *attributesP, UInt16 *versionP, UInt32 *crDateP, UInt32 *modDateP, UInt32 *bckUpDateP, UInt32 *modNumP, LocalID *appInfoIDP, LocalID *sortInfoIDP, UInt32 *typeP, UInt32 *creatorP)`
- Parameters** `-> cardNo` Number of the card the database resides on.

## Data and Resource Manager

### Data Manager Functions

---

-> dbID	Database ID of the database.
<- nameP	The database's name. Pass a pointer to 32-byte character array for this parameter, or NULL if you don't care about the name.
<- attributesP	The database's attribute flags. The section " <a href="#">Database Attribute Constants</a> " lists constants you can use to query the values returned in this parameter. Pass NULL for this parameter if you don't want to retrieve it.
<- versionP	The application-specific version number. The default version number is 0. Pass NULL for this parameter if you don't want to retrieve it.
<- crDateP	The date the database was created, expressed as the number of seconds since the first instant of Jan. 1, 1904. Pass NULL for this parameter if you don't want to retrieve it.
<- modDateP	The date the database was last modified, expressed as the number of seconds since the first instant of Jan. 1, 1904. Pass NULL for this parameter if you don't want to retrieve it.
<- bckUpDateP	The date the database was backed up, expressed as the number of seconds since the first instant of Jan. 1, 1904. Pass NULL for this parameter if you don't want to retrieve it.
<- modNumP	The modification number, which is incremented every time a record in the database is added, modified, or deleted. Pass NULL for this parameter if you don't want to retrieve it.
<- appInfoIDP	The local ID of the application info block, or NULL. The application info block is an optional field that the database may use to store application-specific information about the database. Pass NULL for this parameter if you don't want to retrieve it.

<code>&lt;- sortInfoIDP</code>	The local ID of the database's sort table. This is an optional field in the database header. Pass NULL for this parameter if you don't want to retrieve it.
<code>&lt;- typeP</code>	The database's type, specified when it is created. Pass NULL for this parameter if you don't want to retrieve it.
<code>&lt;- creatorP</code>	The database's creator, specified when it is created. Pass NULL for this parameter if you don't want to retrieve it.

**Result** Returns `errNone` if no error, or [dmErrInvalidParam](#) if an error occurs.

**Compatibility** Updating of the modification date differs based on which version of the OS your application is running on.

- Under Palm OS 1.0, the modification date is never updated.
- Under Palm OS 2.0, the modification date is updated every time a database opened with write access is closed.
- Beginning with Palm OS 3.0, the modification date is updated only if a change has been made to the database opened with write access. (The update still occurs upon closing the database.) Changes that trigger an update include adding, deleting, archiving, rearranging, or resizing records, setting a record's dirty bit in [DmReleaseRecord](#), rearranging or deleting categories, or updating the database header fields using [DmSetDatabaseInfo](#).

If you need to ensure that the modification date is updated the same way regardless of the operating system version, use [DmSetDatabaseInfo](#) to set the modification date explicitly.

**See Also** [DmSetDatabaseInfo](#), [DmDatabaseSize](#), [DmOpenDatabaseInfo](#), [DmFindDatabase](#), [DmGetNextDatabaseByTypeCreator](#), [TimSecondsToDateTime](#)

## DmDatabaseProtect

- Purpose** Increment or decrement the database's protection count.
- Declared In** DataMgr.h
- Prototype** `Err DmDatabaseProtect (UInt16 cardNo, LocalID dbID, Boolean protect)`
- Parameters**
- |            |  |
|------------|--|
| -> cardNo  | Card number of database to protect/unprotect.  |
| -> dbID    | Local ID of database to protect/unprotect.   |
| -> protect | If true, protect count will be incremented. If false, protect count will be decremented. |
- Result** Returns `errNone` if no error, or one of the following if an error occurs:
- [memErrCardNotPresent](#)
  - [dmErrROMBased](#)
  - [dmErrCantFind](#)
  - [memErrNotEnoughSpace](#)
  - [dmErrDatabaseNotProtected](#)
- Comments** This routine can be used to prevent a database from being deleted (by passing `true` for the `protect` parameter). It increments the protect count if `protect` is `true` and decrements it if `protect` is `false`. All `true` calls should be balanced by `false` calls before the application terminates.
- Use this function if you want to keep a particular record or resource in a database locked down but don't want to keep the database open. This information is kept in the dynamic heap, so all databases are "unprotected" at system reset.
- If the database is a resource database that has an overlay associated with it for the current locale, the overlay is also protected or unprotected by this call.

**Compatibility**    Implemented only if [2.0 New Feature Set](#) is present. Overlay support is only available if [3.5 New Feature Set](#) is present.

## **DmDatabaseSize**

**Purpose**            Retrieve size information on a database.

**Declared In**     DataMgr.h

**Prototype**       Err DmDatabaseSize (UInt16 cardNo, LocalID dbID,  
                          UInt32 \*numRecordsP, UInt32 \*totalBytesP,  
                          UInt32 \*dataBytesP)

**Parameters**

-> cardNo	Card number the database resides on.
-> dbID	Database ID of the database.
<- numRecordsP	The total number of records in the database. Pass NULL for this parameter if you don't want to retrieve it.
<- totalBytesP	The total number of bytes used by the database including the overhead. Pass NULL for this parameter if you don't want to retrieve it.
<- dataBytesP	The total number of bytes used to store just each record's data, not including overhead. Pass NULL for this parameter if you don't want to retrieve it.

**Result**            Returns errNone if no error, or [dmErrMemError](#) if an error occurs.

**See Also**         [DmDatabaseInfo](#), [DmOpenDatabaseInfo](#), [DmFindDatabase](#),  
[DmGetNextDatabaseByTypeCreator](#)

## DmDeleteCategory

- Purpose** Delete all records in a category. The category name is not changed.
- Declared In** `DataMgr.h`
- Prototype** `Err DmDeleteCategory (DmOpenRef dbR, UInt16 categoryNum)`
- Parameters**
- > `dbR` Database access pointer.
  - > `categoryNum` Category of records to delete. Category masks such as `dmAllCategories` are invalid.
- Result** Returns `errNone` if no error, or one of the following if an error occurs:
- [dmErrReadOnly](#)
  - [memErrInvalidParam](#)
- Some releases may display a fatal error message instead of returning the error code.
- Comments** This function deletes all records in a category, but does not delete the category itself (note that it deletes the record data and header info, and doesn't just set the deleted bit). For each record in the category, `DmDeleteCategory` marks the `delete` bit in the database header for the record and disposes of the record's data chunk. The record entry in the database header remains, but its `localChunkID` is set to `NULL`.
- If the category contains no records, this function does nothing and returns `errNone` to indicate success. The `categoryNum` parameter is assumed to represent a single category. If you pass a category mask to specify more than one category, this function interprets that value as a single category, finds no records to delete in that category, and returns `errNone`.
- You can use the [DmRecordInfo](#) call to obtain a category index from a given record. For example:

```
DmOpenRef myDB;
UInt16 record, attr, category, total;

DmRecordInfo(myDB, record, &attr, NULL, NULL);
category = attr & dmRecAttrCategoryMask;
err = DmDeleteCategory(myDB, category);
```

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## DmDeleteDatabase

**Purpose** Delete a database and all its records.

**Declared In** DataMgr.h

**Prototype** Err DmDeleteDatabase (UInt16 cardNo, LocalID dbID)

**Parameters**

-> cardNo	Card number the database resides on.
-> dbID	Database ID.

**Result** Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrCantFind](#)
- [dmErrCantOpen](#)
- [memErrChunkLocked](#)
- [dmErrDatabaseOpen](#)
- [dmErrROMBased](#)
- [memErrInvalidParam](#)
- [memErrNotEnoughSpace](#)

**Comments** Call this routine to delete a database. This routine deletes the database, the application info block, the sort info block, and any other overhead information that is associated with this database. After deleting the database, this function enqueues a deferred [sysNotifyDBDeletedEvent](#) notification, which will be broadcast at the top of the event loop.

## Data and Resource Manager

### Data Manager Functions

---

If the database has an overlay associated with it, this function does **not** delete the overlay. You can delete the overlay with a separate call to `DmDeleteDatabase`.

This routine accepts a database ID as a parameter. To determine the database ID, call either [DmFindDatabase](#) or [DmGetDatabase](#) with a database index.

**Compatibility** The [sysNotifyDBDeletedEvent](#) notification is only broadcast if the [4.0 New Feature Set](#) is present.

**See Also** [DmDeleteRecord](#), [DmRemoveRecord](#), [DmRemoveResource](#), [DmCreateDatabase](#), [DmGetNextDatabaseByTypeCreator](#), [DmFindDatabase](#)

## DmDeleteRecord

**Purpose** Delete a record's chunk from a database but leave the record entry in the header and set the delete bit for the next sync.

**Declared In** `DataMgr.h`

**Prototype** `Err DmDeleteRecord (DmOpenRef dbP, UInt16 index)`

**Parameters**

-> dbP	DmOpenRef to open database.
-> index	Which record to delete.

**Result** Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrReadOnly](#)
- [dmErrIndexOutOfRange](#)
- [dmErrRecordArchived](#)
- [dmErrRecordDeleted](#)
- [memErrInvalidParam](#)

Some releases may display a fatal error message instead of returning the error code.

**Comments** Marks the delete bit in the database header for the record and disposes of the record's data chunk. Does not remove the record entry from the database header, but simply sets the localChunkID of the record entry to NULL.

**See Also** [DmDetachRecord](#), [DmRemoveRecord](#), [DmArchiveRecord](#), [DmNewRecord](#)

## DmDetachRecord

**Purpose** Detach and orphan a record from a database but don't delete the record's chunk.

**Declared In** DataMgr.h

**Prototype** Err DmDetachRecord (DmOpenRef dbP, UInt16 index, MemHandle \*oldHP)

**Parameters**

-> dbP	DmOpenRef to open.
-> index	Index of the record to detach.
<-> oldHP	Pointer to return handle of the detached record.

**Result** Returns errNone if no error, or one of the following if an error occurs:

- [dmErrReadOnly](#)
- [dmErrIndexOutOfRange](#)
- [dmErrNotRecordDB](#)
- [memErrChunkLocked](#)
- [memErrInvalidParam](#)

Some releases may display a fatal error message instead of returning the error code.

**Comments** This routine detaches a record from a database by removing its entry from the database header and returns the handle of the record's data chunk in \*oldHP. Unlike [DmDeleteRecord](#), this

## Data and Resource Manager

### Data Manager Functions

---

routine removes its entry in the database header but it does not delete the actual record.

**See Also** [DmAttachRecord](#), [DmRemoveRecord](#), [DmArchiveRecord](#), [DmDeleteRecord](#)

## DmDetachResource

**Purpose** Detach a resource from a database and return the handle of the resource's data.

**Declared In** DataMgr.h

**Prototype** Err DmDetachResource (DmOpenRef dbP,  
UInt16 index, MemHandle \*oldHP)

**Parameters**

-> dbP	DmOpenRef to open database.
-> index	Index of resource to detach.
<-> oldHP	Pointer to return handle of the detached record.

**Result** Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrReadOnly](#)
- [dmErrIndexOutOfRange](#)
- [dmErrCorruptDatabase](#)
- [memErrChunkLocked](#)
- [memErrInvalidParam](#)

Some releases may display a fatal error message instead of returning the error code. All releases may display a fatal error message if the database is not a resource database.

**Comments** This routine detaches a resource from a database by removing its entry from the database header and returns the handle of the resource's data chunk in `*oldHP`.

**See Also** [DmAttachResource](#), [DmRemoveResource](#)

## **DmFindDatabase**

- Purpose** Return the database ID of a database by card number and name.
- Declared In** `DataMgr.h`
- Prototype** `LocalID DmFindDatabase (UInt16 cardNo,  
const Char *nameP)`
- Parameters**
- > `cardNo`            Number of card to search.
  - > `nameP`             Name of the database to look for.
- Result** Returns the database ID. If the database can't be found, this function returns 0, and [DmGetLastError](#) returns an error code indicating the reason for failure.
- See Also** [DmGetNextDatabaseByTypeCreator](#), [DmDatabaseInfo](#),  
[DmOpenDatabase](#)

## **DmFindRecordByID**

- Purpose** Return the index of the record with the given unique ID.
- Declared In** `DataMgr.h`
- Prototype** `Err DmFindRecordByID (DmOpenRef dbP,  
UInt32 uniqueID, UInt16 *indexP)`
- Parameters**
- > `dbP`                 Database access pointer.
  - > `uniqueID`            Unique ID to search for.
  - <- `indexP`             Return index.
- Result** Returns 0 if found, otherwise [dmErrUniqueIDNotFound](#). May display a fatal error message if the unique ID is invalid.
- See Also** [DmQueryRecord](#), [DmGetRecord](#), [DmRecordInfo](#)

## DmFindResource

- Purpose** Search the given database for a resource by type and ID, or by pointer if it is non-NULL.
- Declared In** `DataMgr.h`
- Prototype** `UInt16 DmFindResource (DmOpenRef dbP, DmResType resType, DmResID resID, MemHandle resH)`
- Parameters**
- > `dbP` Open resource database access pointer.
  - > `resType` Type of resource to search for.
  - > `resID` ID of resource to search for.
  - > `resH` Pointer to locked resource, or NULL.
- Result** Returns index of resource in resource database, or 0xFFFF if not found.  
May display a fatal error message if the database is not a resource database.
- Comments** Use this routine to find a resource in a particular resource database by type and ID or by pointer. It is particularly useful when you want to search only one database for a resource and that database is not the topmost one.

---

**IMPORTANT:** This function searches for the resource only in the database you specify. If you pass a pointer to a base resource database, its overlay is **not** searched. To search both a base database and its overlay for a localized resource, use [DmGet1Resource](#) instead of this function.

---

If `resH` is NULL, the resource is searched for by type and ID.

If `resH` is not NULL, `resType` and `resID` are ignored and the index of the given locked resource is returned.

Once the index of a resource is determined, it can be locked down and accessed by calling [DmGetResourceIndex](#).

**See Also** [DmGetResource](#), [DmSearchResource](#), [DmResourceInfo](#), [DmGetResourceIndex](#), [DmFindResourceType](#)

## DmFindResourceType

**Purpose** Search the given database for a resource by type and type index.

**Declared In** DataMgr.h

**Prototype** UInt16 DmFindResourceType (DmOpenRef dbP,  
DmResType resType, UInt16 typeIndex)

**Parameters**

- > dbP                    Open resource database access pointer.
- > resType                Type of resource to search for.
- > typeIndex             Index of given resource type.

**Result** Index of resource in resource database, or 0xFFFF if not found.  
May display a fatal error message if the database is not a resource database.

**Comments** Use this routine to retrieve all the resources of a given type in a resource database. By starting at typeIndex 0 and incrementing until an error is returned, the total number of resources of a given type and the index of each of these resources can be determined. Once the index of a resource is determined, it can be locked down and accessed by calling [DmGetResourceIndex](#).

## Data and Resource Manager

### Data Manager Functions

---

---

**IMPORTANT:** This function searches for resources only in the database you specify. If you pass a pointer to a base resource database, its overlay is **not** searched. To search both a base database and its overlay for a localized resource, use [DmGet1Resource](#) instead of this function.

---

**See Also** [DmGetResource](#), [DmSearchResource](#), [DmResourceInfo](#), [DmGetResourceIndex](#), [DmFindResource](#)

## DmFindSortPosition

**Purpose** Returns where in a sorted list of records a given record would be located. Useful to find where to insert a record with [DmAttachRecord](#). Uses a binary search.

**Declared In** DataMgr.h

**Prototype** UInt16 DmFindSortPosition (DmOpenRef dbP,  
void \*newRecord, SortRecordInfoPtr newRecordInfo,  
DmComparF \*compar, Int16 other)

**Parameters**

- > dbP Database access pointer.
- > newRecord Pointer to the new record.
- > newRecordInfo Sort information about the new record. See [SortRecordInfoType](#).
- > compar Pointer to comparison function. See [DmComparF](#).

-> other

Any value the application wants to pass to the comparison function. This parameter is often used to indicate a sort direction (ascending or descending).

**Result** The position where the record should be inserted.

The position should be viewed as between the record returned and the record before it. Note that the return value may be one greater than the number of records.

**Comments** If `newRecord` has the same key as another record in the database, `DmFindSortPosition` assumes that `newRecord` should be inserted after that record. If there are several records with the same key, `newRecord` is inserted after all of them. For this reason, if you use `DmFindSortPosition` to search for the location of a record that you know is already in the database, you must subtract 1 from the result. (Be sure to check that the value is not 0.)

If there are deleted records in the database, `DmFindSortPosition` only works if those records are at the end of the database. `DmFindSortPosition` always assumes that a deleted record is greater than or equal to any other record.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [DmFindSortPositionV10](#)

## **DmFindSortPositionV10**

**Purpose** Return where a record should be. Useful to find where to insert a record with [DmAttachRecord](#). Uses a binary search.

**Declared In** `DataMgr.h`

**Prototype** `UInt16 DmFindSortPositionV10 (DmOpenRef dbP, void *newRecord, DmComparF *compar, Int16 other)`

**Parameters** -> `dbP` Database access pointer.

## Data and Resource Manager

### Data Manager Functions

---

- > newRecord      Pointer to the new record.
- > compar          Pointer to comparison function. See [DmComparF](#).
- > other            Any value the application wants to pass to the comparison function.

**Result**      Returns the position where the record should be inserted. The position should be viewed as between the record returned and the record before it. Note that the return value may be one greater than the number of records.

**Comments**    If there are deleted records in the database, `DmFindSortPositionV10` only works if those records are at the end of the database. `DmFindSortPositionV10` always assumes that a deleted record is greater than or equal to any other record.

**Compatibility**    This function corresponds to the 1.0 version of `DmFindSortPosition`.

**See Also**        [DmFindSortPosition](#), [DmQuickSort](#), [DmInsertionSort](#)

## DmGetAppInfoID

**Purpose**          Return the local ID of the application info block.

**Declared In**     `DataMgr.h`

**Prototype**       `LocalID DmGetAppInfoID (DmOpenRef dbP) .`

**Parameters**     -> dbP            Database access pointer.

**Result**          Returns local ID of the application info block. The application info block is an optional field that the database may use to store application-specific information about the database; if the database doesn't have an application info block, `DmGetAppInfoID` returns zero.

**See Also**        [DmDatabaseInfo](#), [DmOpenDatabase](#)

## **DmGetDatabase**

- Purpose** Return the database header ID of a database by index and card number.
- Declared In** `DataMgr.h`
- Prototype** `LocalID DmGetDatabase (UInt16 cardNo, UInt16 index)`
- Parameters**
- > `cardNo` Card number of database.
  - > `index` Index of database.
- Result** Returns the database ID, or 0 if an invalid parameter is passed.
- Comments** Call this routine to retrieve the database ID of a database by index. The index should range from 0 to [DmNumDatabases-1](#).  
This routine is useful for getting a directory of all databases on a card. The databases returned may reside in either the ROM or the RAM. The order in which databases are returned is not fixed; therefore, you should not rely on receiving a list of databases in a particular order.
- See Also** [DmOpenDatabase](#), [DmNumDatabases](#), [DmDatabaseInfo](#), [DmDatabaseSize](#)

## **DmGetDatabaseLockState**

- Purpose** Return information about the number of locked and busy records in a database.
- Declared In** `DataMgr.h`
- Prototype** `void DmGetDatabaseLockState (DmOpenRef dbR, UInt8 *highest, UInt32 *count, UInt32 *busy)`
- Parameters**
- > `dbR` Database access pointer.

## Data and Resource Manager

### Data Manager Functions

---

<code>&lt;- highest</code>	The highest lock count found for all of the records in the database. If a database has two records, one has a lock count of 2 and one has a lock count of 1, the highest lock count is 2. Pass <code>NULL</code> for this parameter if you don't want to retrieve it.
<code>&lt;- count</code>	The number of records that have the lock count that is returned in the <code>highest</code> parameter. Pass <code>NULL</code> for this parameter if you don't want to retrieve it.
<code>&lt;- busy</code>	The number of records that have the busy bit set. Pass <code>NULL</code> for this parameter if you don't want to retrieve it.

**Result** No return value. Returns all information in the parameters you pass.

**Comments** This function is intended to be used for debugging purposes. You can use it to obtain information about how many records are busy and how much locking occurs.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

## DmGetLastError

**Purpose** Return error code from last data manager call.

**Declared In** `DataMgr.h`

**Prototype** `Err DmGetLastError (void)`

**Parameters** None.

**Result** Error code from last unsuccessful data manager call.

**Comments** Use this routine to determine why a data manager call failed. In particular, calls like [DmGetRecord](#) return 0 if unsuccessful, so

calling [DmGetLastError](#) is the only way to determine why they failed.

Note that `DmGetLastError` does not always reflect the error status of the last data manager call. Rather, it reflects the error status of data manager calls that don't return an error code. For some of those calls, the saved error code value is not set to 0 when the call is successful.

For example, if a call to [DmOpenDatabaseByTypeCreator](#) returns NULL for database reference (that is, it fails), `DmGetLastError` returns something meaningful; otherwise, it returns the error value of some previous data manager call.

Only the following data manager functions currently affect the value returned by `DmGetLastError`:

---

<a href="#">DmFindDatabase</a>	<a href="#">DmOpenDatabaseByTypeCreator</a>
<a href="#">DmOpenDatabase</a>	<a href="#">DmNewRecord</a>
<a href="#">DmQueryRecord</a>	<a href="#">DmGetRecord</a>
<a href="#">DmQueryNextInCategory</a>	<a href="#">DmPositionInCategory</a>
<a href="#">DmSeekRecordInCategory</a>	<a href="#">DmResizeRecord</a>
<a href="#">DmGetResource</a>	<a href="#">DmGet1Resource</a>
<a href="#">DmNewResource</a>	<a href="#">DmGetResourceIndex</a>
<a href="#">DmNewHandle</a>	<a href="#">DmOpenDBNoOverlay</a>
<a href="#">DmResizeResource</a>	

---

## DmGetNextDatabaseByTypeCreator

- Purpose** Return a database header ID and card number given the type and/or creator. This routine searches all memory cards for a match.
- Declared In** `DataMgr.h`
- Prototype**
- ```
Err DmGetNextDatabaseByTypeCreator
( Boolean newSearch, DmSearchStatePtr stateInfoP,
  UInt32 type, UInt32 creator,
  Boolean onlyLatestVers, UInt16 *cardNoP,
  LocalID *dbIDP)
```
- Parameters**
- > `newSearch` true if starting a new search.
  - <-> `stateInfoP` If `newSearch` is false, this must point to the same data used for the previous invocation.
  - > `type` Type of database to search for, pass 0 as a wildcard.
  - > `creator` Creator of database to search for, pass 0 as a wildcard.
  - > `onlyLatestVers` If true, only the latest version of a database with a given type and creator is returned.
  - <- `cardNoP` On exit, the card number of the found database.
  - <- `dbIDP` Database local ID of the found database.
- Result** Returns `errNone` if no error, or [dmErrCantFind](#) if no matches were found.
- Comments** You may need to call this function successively to discover all databases having a specified type/creator pair.
- To start the search, pass true for `newSearch`. Allocate a `DmSearchStateType` structure and pass it as the `stateInfoP` parameter. `DmGetNextDatabaseByTypeCreator` stores private information in `stateInfoP` and uses it if the search is continued.

To continue a search where the previous one left off, pass `false` for `newSearch` and pass the same `stateInfoP` that you used during the previous call to this function.

You can pass `NULL` as a wildcard operator for the `type` or `creator` parameter to conduct searches of wider scope. If the `type` parameter is `NULL`, this routine can be called successively to return all databases of the given creator. If the `creator` parameter is `NULL`, this routine can be called successively to return all databases of the given type. You can also pass `NULL` as the value for both of these parameters to return all available databases without regard to type or creator.

Because databases are scattered freely throughout memory space, they are not returned in any particular order—any database matching the specified type/creator criteria can be returned. Thus, if the value of the `onlyLatestVers` parameter is `false`, this function may return a database which is not the most recent version matching the specified type/creator pair. To obtain only the latest version of a database matching the search criteria, set the value of the `onlyLatestVers` parameter to `true`.

When determining which is the latest version of the database, RAM databases are considered newer than ROM databases that have the same version number. Because of this, you can replace any ROM-based application with your own version of it. Also, a RAM database on card 1 is considered newer than a RAM database on card 0 if the version numbers are identical.

---

**WARNING!** Don't create or delete a database while using `DmGetNextDatabaseByTypeCreator` to iterate through the existing databases. This could cause databases to be skipped, or it could result in a given database being returned more than once.

---

### Compatibility

In Palm OS version 3.1 and higher, if `onlyLatestVers` is `true`, you only receive one matching database for each type/creator pair. In version 3.0 and earlier, you could receive multiple matching databases if `onlyLatestVers` was `true`.

Note that the behavior is different only when you have specified a value for both `type` and `creator` and `onlyLatestVers` is `true`.

## Data and Resource Manager

### Data Manager Functions

---

For example, suppose your application maintains three databases that all have the same type, creator, and version number and you write this code to process them in some way:

```
DmSearchStateType state;
Boolean latestVer;
UInt16 card;
LocalID currentDB = 0;

theErr = DmGetNextDatabaseByTypeCreator(true,
    &state, myType, myCreator, latestVer, &card,
    &currentDB);
while (!theErr && currentDB) {
    /* do something with currentDB */
    /* now get the next DB */
    theErr = DmGetNextDatabaseByTypeCreator(
        false, &state, myType, myCreator,
        vlatestVer, &card, &currentDB);
}
```

If `latestVer` is `false`, then your code will work the same on all versions of Palm OS and will return all three databases whose type and creator match those specified. If `latestVer` is `true`, this code returns all three databases on Palm OS version 3.0 and earlier, but only returns one database on version 3.1 and higher. (Exactly which database it returns is unspecified.)

If you expect multiple databases to match your search criteria, make sure you call `DmGetNextDatabaseByTypeCreator` in one of the following ways to ensure that your code operates the same on all Palm OS versions:

- Set `onlyLatestVers` to `false` if you specify both a type and creator.
- Specify `NULL` for either the type or creator parameter (or both).

**See Also** [DmGetDatabase](#), [DmFindDatabase](#), [DmDatabaseInfo](#), [DmOpenDatabaseByTypeCreator](#), [DmDatabaseSize](#)

## DmGetRecord

- Purpose** Return a handle to a record by index and mark the record busy.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmGetRecord (DmOpenRef dbP,  
UInt16 index)`
- Parameters**
- |          |                             |
|----------|-----------------------------|
| -> dbP   | DmOpenRef to open database. |
| -> index | Which record to retrieve.   |
- Result** Returns a handle to record data. If another call to `DmGetRecord` for the same record is attempted before the record is released, NULL is returned and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Comments** Returns a handle to given record and sets the busy bit for the record.
- If the record is ROM-based (pointer accessed), this routine makes a fake handle to it and stores this handle in the `DmAccessType` structure.
- [DmReleaseRecord](#) should be called as soon as the caller finishes viewing or editing the record.
- See Also** [DmSearchRecord](#), [DmFindRecordByID](#), [DmRecordInfo](#), [DmReleaseRecord](#), [DmQueryRecord](#)

## Data and Resource Manager

### Data Manager Functions

---

## DmGetResource

- Purpose** Search all open resource databases and return a handle to a resource, given the resource type and ID.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmGetResource (DmResType type, DmResID resID)`
- Parameters**
- |          |                    |
|----------|--------------------|
| -> type  | The resource type. |
| -> resID | The resource ID.   |
- Result** Handle to resource data. If the specified resource cannot be found, this function returns NULL and [DmGetLastErr](#) returns an error code indicating the reason for failure.
- Comments** Searches all open resource databases starting with the most recently opened one for a resource of the given type and ID. If found, the resource handle is returned. The application should call [DmReleaseResource](#) as soon as it finishes accessing the resource data. The resource handle is not locked by this function.
- This function always returns the resource located in the overlay if any open overlay has a resource matching that type and ID. If there is no overlay version of the resource, this function returns the resource from the base database.
- See Also** [DmGet1Resource](#), [DmReleaseResource](#), [ResLoadConstant](#)

## DmGetResourceIndex

- Purpose** Return a handle to a resource by index.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmGetResourceIndex (DmOpenRef dbP, UInt16 index)`
- Parameters**
- > `dbP` Access pointer to open database.
  - > `index` Index of the resource whose handle you want.
- Result** Handle to resource data. If the specified index is out of range, this function returns NULL and [DmGetLastError](#) returns an error code indicating the reason for failure.
- May display a fatal error message if the database is not a resource database.

---

**IMPORTANT:** This function accesses the resource only in the database you specify. If you pass a pointer to a base resource database, its overlay is **not** accessed. Therefore, you should use care when using this function to access a potentially localized resource. You can use [DmSearchResource](#) to obtain a pointer to the overlay database if the resource is localized; however, it's more convenient to use [DmGetResource](#) or [DmGet1Resource](#).

---

**See Also** [DmFindResource](#), [DmFindResourceType](#), [DmSearchResource](#)

## Data and Resource Manager

### Data Manager Functions

---

## DmGet1Resource

- Purpose** Search the most recently opened resource database and return a handle to a resource given the resource type and ID.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmGet1Resource (DmResType type, DmResID resID)`
- Parameters**
- > `type`                   The resource type.
  - > `resID`                    The resource ID.
- Result** Handle to resource data. If unsuccessful, this function returns `NULL` and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Comments** Searches the most recently opened resource database for a resource of the given type and ID. If the database has an overlay associated with it, the overlay is searched first, and then the base database is searched if the overlay does not contain the resource. If found, the resource handle is returned. The application should call [DmReleaseResource](#) as soon as it finishes accessing the resource data. The resource handle is not locked by this function.
- See Also** [DmGetResource](#), [DmReleaseResource](#), [ResLoadConstant](#)

## DmInsertionSort

- Purpose** Sort records in a database.
- Declared In** `DataMgr.h`
- Prototype** `Err DmInsertionSort (DmOpenRef dbR, DmComparF *compar, Int16 other)`
- Parameters**
- > `dbR`                        Database access pointer.

- > `compar`      Comparison function. See [DmComparF](#).
- > `other`      Any value the application wants to pass to the comparison function. This parameter is often used to indicate a sort direction (ascending or descending).

**Result**      Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrReadOnly](#)
- [dmErrNotRecordDB](#)

Some releases may display a fatal error message instead of returning the error code.

**Comments**      Deleted records are placed last in any order. All others are sorted according to the passed comparison function. Only records which are out of order move. Moved records are moved to the end of the range of equal records. If a large number of records are being sorted, try to use the quick sort.

The following insertion-sort algorithm is used: Starting with the second record, each record is compared to the preceding record. Each record not greater than the last is inserted into sorted position within those already sorted. A binary insertion is performed. A moved record is inserted after any other equal records.

**See Also**      [DmQuickSort](#)

## **DmMoveCategory**

**Purpose**      Move all records in a category to another category.

**Declared In**      `DataMgr.h`

**Prototype**      `Err DmMoveCategory (DmOpenRef dbP,  
UInt16 toCategory, UInt16 fromCategory,  
Boolean dirty)`

**Parameters**      -> `dbP`      `DmOpenRef` to open database.

## Data and Resource Manager

### Data Manager Functions

---

- >toCategory      Category to which the records should be added.
- > fromCategory   Category from which to remove records.
- > dirty            If true, set the dirty bit.

**Result**      Returns 0 if successful, or [dmErrReadOnly](#) if the database is in read-only mode. Some releases may display a fatal error message instead of returning the error code.

**Comments**    If `dirty` is `true`, the moved records are marked as dirty. The `toCategory` and `fromCategory` parameters hold category index values. You can learn which category a record is in with the [DmRecordInfo](#) call and use that value in this function. For example, the following code, ensures that the records `rec1` and `rec2` are in the same category:

```
DmOpenRef myDB;
UInt16 rec1, rec2;
UInt16 rec1Attr, rec2Attr;
UInt16 category1, category2;

DmRecordInfo (myDB, rec1, &rec1Attr, NULL,
              NULL);
category1 = rec1Attr & dmRecAttrCategoryMask;
DmRecordInfo(myDB, rec2, &rec2Attr, NULL,
              NULL);
category2 = rec2Attr & dmRecAttrCategoryMask;
if (category1 != category2)
    DmMoveCategory(myDB, category1, category2,
                  true);
```

## DmMoveRecord

- Purpose** Move a record from one index to another.
- Declared In** DataMgr.h
- Prototype** Err DmMoveRecord (DmOpenRef dbP, UInt16 from, UInt16 to)
- Parameters**
- > dbP                    DmOpenRef to open database.
  - > from                   Index of record to move.
  - > to                     Where to move the record.
- Result** Returns errNone if no error, or one of the following if an error occurs:
- [dmErrReadOnly](#)
  - [dmErrIndexOutOfRange](#)
  - [dmErrNotRecordDB](#)
  - [dmErrMemError](#)
  - [memErrInvalidParam](#)
  - [memErrChunkLocked](#)
- Some releases may display a fatal error message instead of returning the error code.
- Comments** Insert the record at the to index and move other records down. The to position should be viewed as an insertion position. This value may be one greater than the index of the last record in the database. In cases where to is greater than from, the new index of the record becomes to-1 after the move is complete.

## DmNewHandle

- Purpose** Attempt to allocate a new chunk in the same data heap or card as the database header of the passed database access pointer. If there is not enough space in that data heap, try other heaps.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmNewHandle (DmOpenRef dbP, UInt32 size)`
- Parameters**
- > `dbP` `DmOpenRef` to open database.
  - > `size` Size of new handle.
- Result** Returns the `chunkID` of new chunk. If an error occurs, returns 0, and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Comments** Allocates a new handle of the given size. Ensures that the new handle is in the same memory card as the given database. This guarantees that you can attach the handle to the database as a record to obtain and save its `LocalID` in the `appInfoID` or `sortInfoID` fields of the header.
- The handle should be attached to a database as soon as possible. If it is not attached to a database and the application crashes, the memory used by the new handle is unavailable until the next soft reset.

## DmNewRecord

- Purpose** Return a handle to a new record in the database and mark the record busy.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmNewRecord (DmOpenRef dbP, UInt16 *atP, UInt32 size)`
- Parameters**
- |                            |                                                                                                                                                   |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; dbP</code>     | DmOpenRef to open database.                                                                                                                       |
| <code>&lt;-&gt; atP</code> | Pointer to index where new record should be placed. Specify the value <code>dmMaxRecordIndex</code> to add the record to the end of the database. |
| <code>-&gt; size</code>    | Size of new record.                                                                                                                               |
- Result** Handle to record data. If an error occurs, this function returns 0 and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Some releases may display a fatal error message if the database is opened in read-only mode or it is a resource database.
- Comments** Allocates a new record of the given size, and returns a handle to the record data. The parameter `atP` points to an index variable. The new record is inserted at index `*atP` and all record indices that follow are shifted down. If `*atP` is greater than the number of records currently in the database, the new record is appended to the end and its index is returned in `*atP`.
- Both the `busy` and `dirty` bits are set for the new record and a unique ID is automatically created.
- [DmReleaseRecord](#) should be called as soon as the caller finishes viewing or editing the record.
- See Also** [DmAttachRecord](#), [DmRemoveRecord](#), [DmDeleteRecord](#)

## DmNewResource

- Purpose** Allocate and add a new resource to a resource database.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmNewResource (DmOpenRef dbP,  
DmResType resType, DmResID resID, UInt32 size)`
- Parameters**
- > `dbP` DmOpenRef to open database.
  - > `resType` Type of the new resource.
  - > `resID` ID of the new resource.
  - > `size` Desired size of the new resource.
- Result** Returns a handle to the new resource. If an error occurs, this function returns NULL and [DmGetLastError](#) returns an error code indicating the reason for failure.
- May display a fatal error message if the database is not a resource database.
- Comments** Allocates a memory chunk for a new resource and adds it to the given resource database. The new resource has the given type and ID. If successful, the application should call [DmReleaseResource](#) as soon as it finishes initializing the resource.
- See Also** [DmAttachResource](#), [DmRemoveResource](#)

## **DmNextOpenDatabase**

- Purpose** Return DmOpenRef to next open database for the current task.
- Declared In** DataMgr.h
- Prototype** DmOpenRef DmNextOpenDatabase (DmOpenRef currentP)
- Parameters** -> currentP      Current database access pointer or NULL.
- Result** DmOpenRef to next open database, or NULL if there are no more.
- Comments** Call this routine successively to get the DmOpenRefs of all open databases. Pass NULL for currentP to get the first one. Applications don't usually call this function, but is useful for system information.
- See Also** [DmOpenDatabaseInfo](#), [DmDatabaseInfo](#)

## **DmNextOpenResDatabase**

- Purpose** Return access pointer to next open resource database in the search chain.
- Declared In** DataMgr.h
- Prototype** DmOpenRef DmNextOpenResDatabase (DmOpenRef dbP)
- Parameters** -> dbP      Database reference, or 0 to start search from the top.
- Result** Pointer to next open resource database.
- Comments** Returns pointer to next open resource database. To get a pointer to the first one in the search chain, pass NULL for dbP. This is the database that is searched when [DmGet1Resource](#) is called.

## Data and Resource Manager

### Data Manager Functions

---

If you use this function to access a resource database that might have an overlay associated with it, be careful how you use the result. The `DmOpenRef` returned by this function is a pointer to the overlay database, not the base database. If you subsequently pass this pointer to [DmFindResource](#), you'll receive a handle to the overlaid resource. If you're searching for a resource that is found only in the base, you won't find it. Instead, always use [DmGetResource](#) or [DmGet1Resource](#) to obtain a resource. Both of those functions search both the overlay databases and their associated base databases.

## DmNumDatabases

- Purpose** Determine how many databases reside on a memory card.
- Declared In** `DataMgr.h`
- Prototype** `UInt16 DmNumDatabases (UInt16 cardNo)`
- Parameters** `-> cardNo` Number of the card to check.
- Result** The number of databases found.
- Comments** This routine is helpful for getting a directory of all databases on a card. The routine [DmGetDatabase](#) accepts an index from 0 to [DmNumDatabases](#) -1 and returns a database ID by index.
- See Also** [DmGetDatabase](#)

## DmNumRecords

|                    |                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the number of records in a database.                                                                                                                                                                                                                                                                                            |
| <b>Declared In</b> | DataMgr.h                                                                                                                                                                                                                                                                                                                              |
| <b>Prototype</b>   | UInt16 DmNumRecords (DmOpenRef dbP)                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | -> dbP                    DmOpenRef to open database.                                                                                                                                                                                                                                                                                  |
| <b>Result</b>      | The number of records in a database.                                                                                                                                                                                                                                                                                                   |
| <b>Comments</b>    | Records that have that have the deleted bit set (that is, records that will be deleted during the next synchronization because the user has marked them deleted) are included in the count. If you want to exclude these records from your count, use <a href="#">DmNumRecordsInCategory</a> and pass dmAllCategories as the category. |
| <b>See Also</b>    | <a href="#">DmNumRecordsInCategory</a> , <a href="#">DmRecordInfo</a> ,<br><a href="#">DmSetRecordInfo</a>                                                                                                                                                                                                                             |

## DmNumRecordsInCategory

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the number of records of a specified category in a database.                               |
| <b>Declared In</b> | DataMgr.h                                                                                         |
| <b>Prototype</b>   | UInt16 DmNumRecordsInCategory (DmOpenRef dbP,<br>UInt16 category)                                 |
| <b>Parameters</b>  | -> dbP                    DmOpenRef to open database.<br>-> category              Category index. |
| <b>Result</b>      | The number of records in the category.                                                            |

## Data and Resource Manager

### Data Manager Functions

---

**Comments** Because this function must examine all records in the database, it can be slow to return, especially when called on a large database. Records that have the `deleted` bit set are not counted, and if the user has specified to hide or mask private records, private records are not counted either. You can use the [DmRecordInfo](#) call to obtain a category index from a given record. For example:

```
DmOpenRef myDB;
UInt16 record, attr, category, total;

DmRecordInfo(myDB, record, &attr, NULL, NULL);
category = attr & dmRecAttrCategoryMask;
total = DmNumRecordsInCategory(myDB, category);
```

**See Also** [DmNumRecords](#), [DmQueryNextInCategory](#), [DmPositionInCategory](#), [DmSeekRecordInCategory](#), [DmMoveCategory](#)

## DmNumResources

**Purpose** Return the total number of resources in a given resource database.

**Declared In** `DataMgr.h`

**Prototype** `UInt16 DmNumResources (DmOpenRef dbP)`

**Parameters** `-> dbP` DmOpenRef to open database.

**Result** The total number of resources in the given database. May display a fatal error message if the database is not a resource database.

**Comments** `DmNumResources` only counts the resources in the database indicated by the `DmOpenRef` parameter. If the database is a resource database that has an overlay associated with it, this function only returns the number of resources in the base database, not in the overlay.

## DmOpenDatabase

- Purpose** Open a database and return a reference to it. If the database is a resource database, also open its overlay for the current locale.
- Declared In** `DataMgr.h`
- Prototype** `DmOpenRef DmOpenDatabase (UInt16 cardNo, LocalID dbID, UInt16 mode)`
- Parameters**
- > `cardNo` Card number database resides on.
  - > `dbID` The database ID of the database.
  - > `mode` Which mode to open database in (see "[Open Mode Constants](#)").
- Result** Returns `DmOpenRef` to open database. May display a fatal error message if the database parameter is `NULL`. On all other errors, this function returns 0 and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Comments** Call this routine to open a database for reading or writing.
- This routine returns a `DmOpenRef` which must be used to access particular records in a database. If unsuccessful, 0 is returned and the cause of the error can be determined by calling [DmGetLastError](#).
- When you use this routine to open a resource database in read-only mode, it also opens the overlay associated with this database for the current locale, if it exists. (The function [OmGetCurrentLocale](#) returns the current locale.) Overlays are resource databases typically used to localize applications, shared libraries, and panels. They have the same creator as the base database, a type of 'ovly' (symbolically named `omOverlayDBType`), and contain resources with the same IDs and types as the resources in the base database. When you request a resource from the database using [DmGetResource](#) or [DmGet1Resource](#), the overlay is searched first. If the overlay contains a resource for the given ID, it is returned. If not, the resource from the base database is returned.

## Data and Resource Manager

### Data Manager Functions

---

The `DmOpenRef` returned by this function is the pointer to the base database, not to the overlay database, so care should be taken when passing this pointer to functions such as [DmFindResource](#) because this circumvents the overlay.

It's possible to create a "stripped" base resource database, one that does not contain any user interface resources. `DmOpenDatabase` only opens a stripped database if its corresponding overlay exists. If the overlay does not exist or if the overlay doesn't match the resource database, `DmOpenDatabase` returns `NULL` and [DmGetLastError](#) returns the error code [omErrBaseRequiresOverlay](#).

If you open a resource database in a writable mode, the associated overlay is not opened. If you make changes to the resource database, the overlay database is invalidated if those changes affect any resources that are also in the overlay. This means that on future occasions where you open the resource database in read-only mode, the overlay will not be opened because Palm OS considers it to be invalid.

---

**TIP:** If you want to prevent your resource database from being overlaid, include an 'xprf' resource (symbolically named `sysResTextPrefs`) in the database with the ID 0 (`sysResIDExtPrefs`) and set its `disableOverlays` flag. This resource is defined in `UIResources.r`.

---

#### Compatibility

Overlay support is only available if [3.5 New Feature Set](#) is present. On earlier releases, this function opens resource databases without looking for an associated overlay.

If [4.0 New Feature Set](#) is present, when `DmOpenDatabase` attempts to open a stripped resource database and cannot find an overlay for it, it searches for an overlay matching the default locale if the system locale is different from the default locale.

#### See Also

[DmCloseDatabase](#), [DmCreateDatabase](#), [DmFindDatabase](#), [DmOpenDatabaseByTypeCreator](#), [DmDeleteDatabase](#), [DmOpenDBNoOverlay](#)

## **DmOpenDatabaseByTypeCreator**

- Purpose** Open the most recent revision of a database with the given type and creator. If the database is a resource database, also open its overlay for the current locale.
- Declared In** `DataMgr.h`
- Prototype** `DmOpenRef DmOpenDatabaseByTypeCreator (UInt32 type, UInt32 creator, UInt16 mode)`
- Parameters**
- > `type`           Type of database.
  - > `creator`        Creator of database.
  - > `mode`           Which mode to open database in (see "[Open Mode Constants](#)").
- Result** `DmOpenRef` to open database. If the database couldn't be found, this function returns 0 and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Comments** If you use this routine to open a resource database in read-only mode, it also opens the overlay associated with this database for the current locale. See [DmOpenDatabase](#) for more information on overlays and resource databases.
- Compatibility** Overlay support is only available if [3.5 New Feature Set](#) is present. On earlier releases, this function opens resource databases without looking for an associated overlay.
- See Also** [DmCreateDatabase](#), [DmOpenDatabase](#), [DmOpenDatabaseInfo](#), [DmCloseDatabase](#), [DmOpenDBNoOverlay](#)

## DmOpenDatabaseInfo

- Purpose** Retrieve information about an open database.
- Declared In** `DataMgr.h`
- Prototype** `Err DmOpenDatabaseInfo (DmOpenRef dbP, LocalID *dbIDP, UInt16 *openCountP, UInt16 *modeP, UInt16 *cardNoP, Boolean *resDBP)`
- Parameters**
- |                            |                                                                                                                                                                                   |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>dbP</code>        | DmOpenRef to open database.                                                                                                                                                       |
| <- <code>dbIDP</code>      | The ID of the database. Pass NULL for this parameter if you don't want to retrieve this information.                                                                              |
| <- <code>openCountP</code> | The number of applications that have this database open. Pass NULL for this parameter if you don't want to retrieve this information.                                             |
| <- <code>modeP</code>      | The mode used to open the database (see " <a href="#">Open Mode Constants</a> "). Pass NULL for this parameter if you don't want to retrieve this information.                    |
| <- <code>cardNoP</code>    | The number of the card on which this database resides. Pass NULL for this parameter if you don't want to retrieve this information.                                               |
| <- <code>resDBP</code>     | If <code>true</code> upon return, the database is a resource database, <code>false</code> otherwise. Pass NULL for this parameter if you don't want to retrieve this information. |
- Result** Returns `errNone` if no error.
- See Also** [DmDatabaseInfo](#)

## **DmOpenDBNoOverlay**

|                      |                                                                                                                                                                                                                                                                                                                                                                          |           |                                  |         |                                  |         |                                                                               |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|----------------------------------|---------|----------------------------------|---------|-------------------------------------------------------------------------------|
| <b>Purpose</b>       | Open a database and return a reference to it.                                                                                                                                                                                                                                                                                                                            |           |                                  |         |                                  |         |                                                                               |
| <b>Declared In</b>   | DataMgr.h                                                                                                                                                                                                                                                                                                                                                                |           |                                  |         |                                  |         |                                                                               |
| <b>Prototype</b>     | DmOpenRef DmOpenDBNoOverlay (UInt16 cardNo, LocalID dbID, UInt16 mode)                                                                                                                                                                                                                                                                                                   |           |                                  |         |                                  |         |                                                                               |
| <b>Parameters</b>    | <table><tr><td>-&gt; cardNo</td><td>Card number database resides on.</td></tr><tr><td>-&gt; dbID</td><td>The database ID of the database.</td></tr><tr><td>-&gt; mode</td><td>Which mode to open database in (see "<a href="#">Open Mode Constants</a>").</td></tr></table>                                                                                              | -> cardNo | Card number database resides on. | -> dbID | The database ID of the database. | -> mode | Which mode to open database in (see " <a href="#">Open Mode Constants</a> "). |
| -> cardNo            | Card number database resides on.                                                                                                                                                                                                                                                                                                                                         |           |                                  |         |                                  |         |                                                                               |
| -> dbID              | The database ID of the database.                                                                                                                                                                                                                                                                                                                                         |           |                                  |         |                                  |         |                                                                               |
| -> mode              | Which mode to open database in (see " <a href="#">Open Mode Constants</a> ").                                                                                                                                                                                                                                                                                            |           |                                  |         |                                  |         |                                                                               |
| <b>Result</b>        | DmOpenRef to open database. May display a fatal error message if the database parameter is NULL. On all other errors, this function returns 0 and <a href="#">DmGetLastError</a> returns an error code indicating the reason for failure.                                                                                                                                |           |                                  |         |                                  |         |                                                                               |
| <b>Comments</b>      | <p>Call this routine to open a database for reading or writing, while ignoring any overlay databases that might be associated with it.</p> <p>This routine returns a DmOpenRef which must be used to access particular records in a database. If unsuccessful, 0 is returned and the cause of the error can be determined by calling <a href="#">DmGetLastError</a>.</p> |           |                                  |         |                                  |         |                                                                               |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                      |           |                                  |         |                                  |         |                                                                               |
| <b>See Also</b>      | <a href="#">DmCloseDatabase</a> , <a href="#">DmCreateDatabase</a> , <a href="#">DmFindDatabase</a> , <a href="#">DmOpenDatabaseByTypeCreator</a> , <a href="#">DmDeleteDatabase</a> , <a href="#">DmOpenDatabase</a>                                                                                                                                                    |           |                                  |         |                                  |         |                                                                               |

## DmPositionInCategory

- Purpose** Return a position of a record within the specified category.
- Declared In** `DataMgr.h`
- Prototype** `UInt16 DmPositionInCategory (DmOpenRef dbP, UInt16 index, UInt16 category)`
- Parameters**
- > `dbP` DmOpenRef to open database.
  - > `index` Index of the record.
  - > `category` Index of category to search.
- Result** Returns the position (zero-based). If the specified index is out of range, this function returns 0 and [DmGetLastError](#) returns an error code indicating the reason for failure. Note that this means a 0 return value might indicate either success or failure. If this function returns 0 and `DmGetLastError` returns `errNone`, the return value indicates that this is the first record in the category.
- Comments**
- Because this function must examine all records up to the current record, it can be slow to return, especially when called on a large database.
- Records that have the `deleted` bit set are ignored, and if the user has specified that private records should be hidden or masked, private records are ignored as well.
- If the record is ROM-based (pointer accessed) this routine makes a fake handle to it and stores this handle in the `DmAccessType` structure.
- To learn which category a record is in, use [DmRecordInfo](#).
- See Also** [DmQueryNextInCategory](#), [DmSeekRecordInCategory](#), [DmMoveCategory](#)

## DmQueryNextInCategory

- Purpose** Return a handle to the next record in the specified category for reading only (does not set the busy bit).
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmQueryNextInCategory (DmOpenRef dbP, UInt16 *indexP, UInt16 category)`
- Parameters**
- |             |                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> dbP      | DmOpenRef to open database.                                                                                                                                       |
| <-> indexP  | Index of a known record (often retrieved with <a href="#">DmPositionInCategory</a> ). If a “next” record is found, this index is updated to indicate that record. |
| -> category | Index of category to query, or <code>dmAllCategories</code> to find the next record in any category.                                                              |
- Result** Returns a handle to the record following a known record, along with the index of that record. If a record couldn't be found, this function returns `NULL`, and [DmGetLastError](#) returns an error code indicating the reason for failure.
- Comments** This function begins searching the database from the record at `*indexP` for a record that is in the specified category. If the record at `*indexP` belongs to that category, then a handle to it is returned. If not, the function continues searching until it finds a record in the category.
- Records that have the `deleted` bit set are skipped, and if the user has specified that private records should be hidden or masked, private records are skipped as well.
- Thus, if you want to find the next record in the category after the one you have an index for, increment the index value before calling this function. For example:
- ```
DmOpenRef myDB;
UInt16 record, attr, category, pos;
```

## Data and Resource Manager

### Data Manager Functions

---

```
MemHandle newRecH;

DmRecordInfo(myDB, record, &attr, NULL, NULL);
category = attr & dmRecAttrCategoryMask;
pos = DmPositionInCategory(myDB, record,
    category);
pos++;
newRecH = DmQueryNextInCategory(myDB, &pos,
    category);
```

**See Also** [DmNumRecordsInCategory](#), [DmPositionInCategory](#),  
[DmSeekRecordInCategory](#)

## DmQueryRecord

**Purpose** Return a handle to a record for reading only (does not set the busy bit).

**Declared In** DataMgr.h

**Prototype** MemHandle DmQueryRecord (DmOpenRef dbP,  
UInt16 index)

**Parameters** -> dbP DmOpenRef to open database.  
-> index Which record to retrieve.

**Result** Returns a record handle. If an error occurs, this function returns NULL, and [DmGetLastErr](#) returns an error code indicating the reason for failure.

Some releases may display a fatal error message if the specified index is out of range.

**Comments** Returns a handle to the given record. Use this routine only when viewing the record. This routine successfully returns a handle to the record even if the record is busy.

If the record is ROM-based (pointer accessed) this routine returns the fake handle to it.

## DmQuickSort

<b>Purpose</b>	Sort records in a database.						
<b>Declared In</b>	DataMgr.h						
<b>Prototype</b>	Err DmQuickSort (DmOpenRef dbP, DmComparF *compar, Int16 other)						
<b>Parameters</b>	<table><tr><td>-&gt; dbP</td><td>Database access pointer.</td></tr><tr><td>-&gt; compar</td><td>Comparison function. See <a href="#">DmComparF</a>.</td></tr><tr><td>-&gt; other</td><td>Any value the application wants to pass to the comparison function. This parameter is often used to indicate a sort direction (ascending or descending).</td></tr></table>	-> dbP	Database access pointer.	-> compar	Comparison function. See <a href="#">DmComparF</a> .	-> other	Any value the application wants to pass to the comparison function. This parameter is often used to indicate a sort direction (ascending or descending).
-> dbP	Database access pointer.						
-> compar	Comparison function. See <a href="#">DmComparF</a> .						
-> other	Any value the application wants to pass to the comparison function. This parameter is often used to indicate a sort direction (ascending or descending).						
<b>Result</b>	Returns <code>errNone</code> if no error, or one of the following if an error occurs: <ul style="list-style-type: none"><li>• <a href="#">dmErrReadOnly</a></li><li>• <a href="#">dmErrNotRecordDB</a></li></ul> Some releases may display a fatal error message instead of returning the error code.						
<b>Comments</b>	<p>Deleted records are placed last in any order. All others are sorted according to the passed comparison function.</p> <p>After <code>DmQuickSort</code> returns, equal database records do not have a consistent order. That is, if <code>DmQuickSort</code> is passed two equal records, their resulting order is unpredictable. To prevent records that contain the same data from being rearranged in an unpredictable order, pass the record's unique ID to the comparison function (using the <a href="#">SortRecordInfoType</a> structure).</p> <p><code>DmQuickSort</code> contains its own stack to limit uncontrolled recursion. When the stack is full <code>DmQuickSort</code> instead performs an insertion sort. An insertion sort is also performed when the number of records is low, avoiding the noticeable overhead of a quick sort with a small number of records. Finally, if the records seem mostly</p>						

## Data and Resource Manager

### Data Manager Functions

---

sorted an insertion sort is performed to move only those records that need moving.

**See Also** [DmFindSortPositionV10](#), [DmInsertionSort](#)

## DmRecordInfo

**Purpose** Retrieve the record information as stored in the database header.

**Declared In** `DataMgr.h`

**Prototype** `Err DmRecordInfo (DmOpenRef dbP, UInt16 index, UInt16 *attrP, UInt32 *uniqueIDP, LocalID *chunkIDP)`

**Parameters**

-> dbP	DmOpenRef to open database.
-> index	Index of the record.
<- attrP	The record's attributes. See " <a href="#">Record Attribute Constants</a> ." Pass NULL for this parameter if you don't want to retrieve this value.
<- uniqueIDP	The record's unique ID. Pass NULL for this parameter if you don't want to retrieve this value.
<- chunkIDP	The record's local ID. Pass NULL for this parameter if you don't want to retrieve this value.

**Result** Returns `errNone` if no error or [dmErrIndexOutOfRange](#) if the specified record can't be found. Some releases may display a fatal error message instead of returning the error code.

**See Also** [DmNumRecords](#), [DmSetRecordInfo](#), [DmQueryNextInCategory](#)

## DmReleaseRecord

- Purpose** Clear the busy bit for the given record and set the dirty bit if dirty is true.
- Declared In** DataMgr.h
- Prototype** Err DmReleaseRecord (DmOpenRef dbP, UInt16 index, Boolean dirty)
- Parameters**
- > dbP                    DmOpenRef to open database.
  - > index                 The record to unlock.
  - > dirty                 If true, set the dirty bit.
- Result** Returns errNone if no error, or [dmErrIndexOutOfRange](#) if the specified index is out of range. Some releases may display a fatal error message instead of returning the error code.
- Comments** Call this routine when you finish modifying or reading a record that you've called [DmGetRecord](#) on or created using [DmNewRecord](#).
- See Also** [DmGetRecord](#)

## DmReleaseResource

- Purpose** Release a resource acquired with [DmGetResource](#).
- Declared In** DataMgr.h
- Prototype** Err DmReleaseResource (MemHandle resourceH)
- Parameters**
- > resourceH            Handle to resource.
- Result** Returns errNone if no error.

## Data and Resource Manager

### Data Manager Functions

---

**Comments** Marks a resource as being no longer needed by the application.

**See Also** [DmGet1Resource](#), [DmGetResource](#)

## DmRemoveRecord

**Purpose** Remove a record from a database and dispose of its data chunk.

**Declared In** DataMgr.h

**Prototype** Err DmRemoveRecord (DmOpenRef dbP, UInt16 index)

**Parameters**

-> dbP	DmOpenRef to open database.
-> index	Index of the record to remove.

**Result** Returns `errNone` if no error, or one of the following if an error occurs:

- [dmErrReadOnly](#)
- [dmErrIndexOutOfRange](#)
- [dmErrNotRecordDB](#)
- [memErrChunkLocked](#)
- [memErrInvalidParam](#)

Some releases may display a fatal error message instead of returning the error code.

**Comments** Disposes of a the record's data chunk and removes the record's entry from the database header. `DmRemoveRecord` should only be used for newly-created records that have just been deleted or records that have never been sync'ed.

**See Also** [DmDetachRecord](#), [DmDeleteRecord](#), [DmArchiveRecord](#), [DmNewRecord](#)

## **DmRemoveResource**

- Purpose** Delete a resource from a resource database.
- Declared In** `DataMgr.h`
- Prototype** `Err DmRemoveResource (DmOpenRef dbP, UInt16 index)`
- Parameters**
- > `dbP` DmOpenRef to open database.
  - > `index` Index of resource to delete.
- Result** Returns `errNone` if no error, or one of the following if an error occurs:
- [dmErrCorruptDatabase](#)
  - [dmErrIndexOutOfRange](#)
  - [dmErrReadOnly](#)
  - [memErrChunkLocked](#)
  - [memErrInvalidParam](#)
  - [memErrNotEnoughSpace](#)
- May display a fatal error message if the database is not a resource database.
- Comments** This routine disposes of the memory manager chunk that holds the given resource and removes its entry from the database header.
- See Also** [DmDetachResource](#), [DmRemoveResource](#), [DmAttachResource](#)

## DmRemoveSecretRecords

- Purpose** Remove all secret records.
- Declared In** `DataMgr.h`
- Prototype** `Err DmRemoveSecretRecords (DmOpenRef dbP)`
- Parameters**
- |        |                             |
|--------|-----------------------------|
| -> dbP | DmOpenRef to open database. |
|--------|-----------------------------|
- Result** Returns `errNone` if no error, or one of the following if an error occurs:
- [dmErrReadOnly](#)
  - [dmErrNotRecordDB](#)
- Some releases may display a fatal error message instead of returning the error code.
- See Also** [DmRemoveRecord](#), [DmRecordInfo](#), [DmSetRecordInfo](#)

## DmResizeRecord

- Purpose** Resize a record by index.
- Declared In** `DataMgr.h`
- Prototype** `MemHandle DmResizeRecord (DmOpenRef dbP, UInt16 index, UInt32 newSize)`
- Parameters**
- |            |                             |
|------------|-----------------------------|
| -> dbP     | DmOpenRef to open database. |
| -> index   | Which record to retrieve.   |
| -> newSize | New size of record.         |
- Result** Handle to resized record. Returns `NULL` if there is not enough space to resize the record, and [DmGetLastError](#) returns an error code indicating the reason for failure. Some releases may display a fatal error message instead of returning the error code.

**Comments** This routine reallocates the record in another heap of the same memory card if the current heap is not big enough. If this happens, the handle changes, so be sure to use the returned handle to access the resized record.

## **DmResizeResource**

**Purpose** Resize a resource and return the new handle.

**Declared In** `DataMgr.h`

**Prototype** `MemHandle DmResizeResource (MemHandle resourceH, UInt32 newSize)`

**Parameters**

- > `resourceH` Handle to resource.
- > `newSize` Desired new size of resource.

**Result** Returns a handle to newly sized resource. Returns NULL if there is not enough space to resize the resource, and [DmGetLastError](#) returns an error code indicating the reason for failure. Some releases may display a fatal error message instead of returning the error code.

**Comments** Resizes the resource and returns a new handle. If necessary in order to grow the resource, this routine will reallocate it in another heap on the same memory card that it is currently in.

The handle may change if the resource had to be reallocated in a different data heap because there was not enough space in its present data heap.

## Data and Resource Manager

### Data Manager Functions

---

## DmResourceInfo

- Purpose** Retrieve information on a given resource.
- Declared In** `DataMgr.h`
- Prototype** `Err DmResourceInfo (DmOpenRef dbP, UInt16 index, DmResType *resTypeP, DmResID *resIDP, LocalID *chunkLocalIDP)`
- Parameters**
- > `dbP` DmOpenRef to open database.
  - > `index` Index of resource to get info on.
  - <- `resTypeP` The resource type. Pass NULL if you don't want to retrieve this information.
  - <- `resIDP` The resource ID. Pass NULL if you don't want to retrieve this information.
  - <- `chunkLocalIDP`  
The memory manager local ID of the resource data. Pass NULL if you don't want to retrieve this information.
- Result** Returns `errNone` if no error or [dmErrIndexOutOfRange](#) if an error occurred. May display a fatal error message if the database is not a resource database.
- Comments** If `dbP` is a pointer to a base resource database, the information returned is about the resource from that database alone; this function ignores any associated overlay.
- See Also** [DmGetResource](#), [DmGet1Resource](#), [DmSetResourceInfo](#), [DmFindResource](#), [DmFindResourceType](#)

## DmSearchRecord

- Purpose** Search all open record databases for a record with the handle passed.
- Declared In** `DataMgr.h`
- Prototype** `UInt16 DmSearchRecord (MemHandle rech, DmOpenRef *dbPP)`
- Parameters**
- > `rech` Record handle.
  - <- `dbPP` The database that contains the record `rech`.
- Result** Returns the index of the record and database access pointer; if not found, returns -1 and `*dbPP` is 0.
- See Also** [DmGetRecord](#), [DmFindRecordByID](#), [DmRecordInfo](#)

## DmSearchResource

- Purpose** Search all open resource databases for a resource by type and ID, or by pointer if it is non-NULL.
- Declared In** `DataMgr.h`
- Prototype** `UInt16 DmSearchResource (DmResType resType, DmResID resID, MemHandle resH, DmOpenRef *dbPP)`
- Parameters**
- > `resType` Type of resource to search for.
  - > `resID` ID of resource to search for.
  - > `resH` Pointer to locked resource, or NULL.
  - <- `dbPP` The resource database that contains the specified resource.
- Result** Returns the index of the resource, stores `DmOpenRef` in `dbPP`.

## Data and Resource Manager

### Data Manager Functions

---

**Comments** This routine can be used to find a resource in all open resource databases by type and ID or by pointer. If `resH` is NULL, the resource is searched for by type and ID. If `resH` is not NULL, `resType` and `resID` is ignored and the index of the resource handle is returned. On return, `*dbPP` contains the access pointer of the resource database that the resource was eventually found in. Once the index of a resource is determined, it can be locked down and accessed by calling [DmGetResourceIndex](#).

If any of the open databases are overlaid, this function finds and returns the localized version of the resource when searching by type and creator. In this case, the `dbPP` return value is a pointer to the overlay database, not the base resource database.

**See Also** [DmGetResource](#), [DmFindResourceType](#), [DmResourceInfo](#), [DmFindResource](#)

## DmSeekRecordInCategory

- Purpose** Return the index of the record nearest the offset from the passed record index whose category matches the passed category. (The `offset` parameter indicates the number of records to move forward or backward.)
- Declared In** `DataMgr.h`
- Prototype** `Err DmSeekRecordInCategory (DmOpenRef dbP, UInt16 *indexP, UInt16 offset, Int16 direction, UInt16 category)`
- Parameters**
- > `dbP` DmOpenRef to open database.
  - <-> `index` The index to start the search at. Upon return, contains the index of the record at `offset` from the index that you passed in.
  - > `offset` Offset of the passed record index. This must be a positive number; use `dmSeekBackward` for the `direction` parameter to search backwards.
  - > `direction` Must be either `dmSeekForward` or `dmSeekBackward`.
  - > `category` Category index.
- Result** Returns `errNone` if no error; returns [dmErrIndexOutOfRange](#) or [dmErrSeekFailed](#) if an error occurred.
- Comments** `DmSeekRecordInCategory` searches for a record in the specified category. The search begins with the record at `index`. When it finds a record in the specified category, it decrements the `offset` parameter and continues searching until a match is found and `offset` is 0.
- Because of this, if you use `DmSeekRecordInCategory` to find the nearest matching record in a particular category, you must pass different `offset` parameters if the starting record is in the category than if it isn't. If the record at `index` is in the category, then you

## Data and Resource Manager

### Data Manager Functions

---

must pass an `offset` of 1 to find the next record in the category because the comparison is performed before the `index` value changes. If the record at `index` isn't in the category, you must pass an `offset` of 0 to find the next record in the category. In this case, an `offset` of 1 skips the first matching record.

Records that have the `deleted` bit set are ignored, and if the user has specified that private records should be hidden or masked, private records are ignored as well.

**See Also** [DmNumRecordsInCategory](#), [DmQueryNextInCategory](#), [DmPositionInCategory](#), [DmMoveCategory](#)

## DmSet

**Purpose** Write a specified value into a section of a record. This function also checks the validity of the pointer for the record and makes sure the writing of the record information doesn't exceed the bounds of the record.

**Declared In** `DataMgr.h`

**Prototype** `Err DmSet (void *recordP, UInt32 offset, UInt32 bytes, UInt8 value)`

**Parameters**

-> <code>recordP</code>	Pointer to locked data record (chunk pointer).
-> <code>offset</code>	Offset within record to start writing.
-> <code>bytes</code>	Number of bytes to write.
-> <code>value</code>	Byte value to write.

**Result** Returns `errNone` if no error. May display a fatal error message if the record pointer is invalid or the function overwrites the record.

**Comments** Must be used to write to data manager records because the data storage area is write-protected.

**See Also** [DmWrite](#)

## DmSetDatabaseInfo

<b>Purpose</b>	Set information about a database.																
<b>Declared In</b>	DataMgr.h																
<b>Prototype</b>	<pre>Err DmSetDatabaseInfo (UInt16 cardNo, LocalID dbID, const Char *nameP, UInt16 *attributesP, UInt16 *versionP, UInt32 *crDateP, UInt32 *modDateP, UInt32 *bckUpDateP, UInt32 *modNumP, LocalID *appInfoIDP, LocalID *sortInfoIDP, UInt32 *typeP, UInt32 *creatorP)</pre>																
<b>Parameters</b>	<table><tr><td>-&gt; cardNo</td><td>Card number the database resides on.</td></tr><tr><td>-&gt; dbID</td><td>Database ID of the database.</td></tr><tr><td>-&gt; nameP</td><td>Pointer to the new name of the database, or NULL. A database name can be up to 32 ASCII bytes long, including the null terminator (as specified by dmDBNameLength). Database names must use only 7-bit ASCII characters (0x20 through 0x7E).</td></tr><tr><td>-&gt; attributesP</td><td>Pointer to new attributes variable, or NULL. See "<a href="#">Database Attribute Constants</a>" for a list of possible values.</td></tr><tr><td>-&gt; versionP</td><td>Pointer to new version, or NULL.</td></tr><tr><td>-&gt; crDateP</td><td>Pointer to new creation date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.</td></tr><tr><td>-&gt; modDateP</td><td>Pointer to new modification date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.</td></tr><tr><td>-&gt; bckUpDateP</td><td>Pointer to new backup date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.</td></tr></table>	-> cardNo	Card number the database resides on.	-> dbID	Database ID of the database.	-> nameP	Pointer to the new name of the database, or NULL. A database name can be up to 32 ASCII bytes long, including the null terminator (as specified by dmDBNameLength). Database names must use only 7-bit ASCII characters (0x20 through 0x7E).	-> attributesP	Pointer to new attributes variable, or NULL. See " <a href="#">Database Attribute Constants</a> " for a list of possible values.	-> versionP	Pointer to new version, or NULL.	-> crDateP	Pointer to new creation date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.	-> modDateP	Pointer to new modification date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.	-> bckUpDateP	Pointer to new backup date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.
-> cardNo	Card number the database resides on.																
-> dbID	Database ID of the database.																
-> nameP	Pointer to the new name of the database, or NULL. A database name can be up to 32 ASCII bytes long, including the null terminator (as specified by dmDBNameLength). Database names must use only 7-bit ASCII characters (0x20 through 0x7E).																
-> attributesP	Pointer to new attributes variable, or NULL. See " <a href="#">Database Attribute Constants</a> " for a list of possible values.																
-> versionP	Pointer to new version, or NULL.																
-> crDateP	Pointer to new creation date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.																
-> modDateP	Pointer to new modification date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.																
-> bckUpDateP	Pointer to new backup date variable, or NULL. Specify the value as a number of seconds since Jan. 1, 1904.																

## Data and Resource Manager

### Data Manager Functions

---

-> modNumP	Pointer to new modification number variable, or NULL.
-> appInfoIDP	Pointer to new appInfoID variable, or NULL.
-> sortInfoIDP	Pointer to new sortInfoID variable, or NULL.
-> typeP	Pointer to new type variable, or NULL.
-> creatorP	Pointer to new creator variable, or NULL.

**Result** Returns `errNone` if no error or one of the following if an error occurred:

- [dmErrInvalidDatabaseName](#)
- [dmErrAlreadyExists](#)
- [dmErrInvalidParam](#)

**Comments** When this call changes `appInfoID` or `sortInfoID`, the old chunk ID (if any) is marked as an orphaned chunk<sup>1</sup> and the new chunk ID is un-orphaned. Consequently, you shouldn't replace an existing `appInfoID` or `sortInfoID` if that chunk has already been attached to another database.

Call this routine to set any or all information about a database except for the card number and database ID. This routine sets the new value for any non-NULL parameter.

**See Also** [DmDatabaseInfo](#), [DmOpenDatabaseInfo](#), [DmFindDatabase](#), [DmGetNextDatabaseByTypeCreator](#), [TimDateTimeToSeconds](#)

---

1. An "orphaned chunk" is one that is allocated in the storage heap, but to which nothing refers. If the orphaned chunk is not put into a database as a record, an `appInfo` block, or the like, and if the application doesn't keep track of it—in a global variable, perhaps—it could get lost. If the application doesn't get around to freeing the chunk before it quits or crashes, or before the device is reset, that storage will be forever unusable: the user can't delete it since the user only deletes databases.

During a soft reset, the OS walks through the storage heap and frees any orphaned chunks that it finds. Since most users reset only rarely, however, you shouldn't rely on this happening.

## DmSetRecordInfo

- Purpose** Set record information stored in the database header.
- Declared In** `DataMgr.h`
- Prototype** `Err DmSetRecordInfo (DmOpenRef dbP, UInt16 index, UInt16 *attrP, UInt32 *uniqueIDP)`
- Parameters**
- > `dbP` DmOpenRef to open database.
  - > `index` Index of record.
  - > `attrP` Pointer to new attribute variable, or NULL. See [“Record Attribute Constants”](#) for a list of possible values.
  - > `uniqueIDP` Pointer to new unique ID variable, or NULL.
- Result** Returns `errNone` if no error, or one of the following if an error occurred:
- [dmErrReadOnly](#)
  - [dmErrNotRecordDB](#)
  - [dmErrIndexOutOfRange](#)
- Some releases may display a fatal error message instead of returning the error code.
- Comments** Sets information about a record. This routine cannot be used to set the `dmRecAttrBusy` bit; instead, use [DmGetRecord](#) to set the bit and [DmReleaseRecord](#) to clear it.
- Normally, the unique ID for a record is automatically created by the data manager when a record is created using [DmNewRecord](#), so an application would not typically change the unique ID.
- See Also** [DmNumRecords](#), [DmRecordInfo](#)

## DmSetResourceInfo

- Purpose** Set information on a given resource.
- Declared In** `DataMgr.h`
- Prototype**

```
Err DmSetResourceInfo (DmOpenRef dbP,  
    UInt16 index, DmResType *resTypeP,  
    DmResID *resIDP)
```
- Parameters**
- |             |  |
|-------------|--|
| -> dbP      | DmOpenRef to open database.                      |
| -> index    | Index of resource to set info for.               |
| -> resTypeP | Pointer to new resType (resource type), or NULL. |
| -> resIDP   | Pointer to new resource ID, or NULL.             |
- Result** Returns `errNone` if no error, or one of the following if an error occurred:
- [dmErrIndexOutOfRange](#)
  - [dmErrReadOnly](#)
- May display a fatal error message if the database is not a resource database.
- Comments** Use this routine to set all or a portion of the information on a particular resource. Any or all of the new info pointers can be NULL. If not NULL, the type and ID of the resource are changed to \*resTypeP and \*resIDP.

## **DmStrCopy**

**Purpose** Copies a string to a record within a database that is open for writing.

**Declared In** `DataMgr.h`

**Prototype** `Err DmStrCopy (void *recordP, UInt32 offset, const Char *srcP)`

## Data and Resource Manager

### Data Manager Functions

---

- Parameters**
- `<-> recordP` Pointer to data record (chunk pointer).
  - `-> offset` Offset within record to start writing.
  - `-> srcP` Pointer to null-terminated string.
- Result** Returns `errNone` if no error. May display a fatal error message if the record pointer is invalid or the function overwrites the record.
- Comments** This is one of the routines that must be used to write to Data Manager records; because the data storage area is write-protected, you cannot write to it directly. This routine checks the validity of the chunk pointer for the record to insure that writing the record will not exceed the chunk bounds. `DmStrCopy` is a convenience method that determines the size of the supplied string and then simply calls [DmWrite](#).

**See Also** [DmSet](#)

## DmWrite

- Purpose** Copies a specified number of bytes to a record within a database that is open for writing.
- Declared In** `DataMgr.h`
- Prototype** `Err DmWrite (void *recordP, UInt32 offset, const void *srcP, UInt32 bytes)`
- Parameters**
- `<-> recordP` Pointer to locked data record (chunk pointer).
  - `-> offset` Offset within record to start writing.
  - `-> srcP` Pointer to data to copy into record.
  - `-> bytes` Number of bytes to write.
- Result** Returns `errNone` if no error. May display a fatal error message if the record pointer is invalid or the function overwrites the record.

**Comments** This is one of the routines that must be used to write to Data Manager records; because the data storage area is write-protected, you cannot write to it directly. This routine checks the validity of the chunk pointer for the record to insure that writing the record will not exceed the chunk bounds.

**See Also** [DmStrCopy](#), [DmSet](#)

## DmWriteCheck

**Purpose** Check the parameters of a write operation to a data storage chunk before actually performing the write.

**Declared In** DataMgr.h

**Prototype** Err DmWriteCheck (void \*recordP, UInt32 offset, UInt32 bytes)

**Parameters**

-> recordP	Locked pointer to recordH.
-> offset	Offset into record to start writing.
-> bytes	Number of bytes to write.

**Result** Returns errNone if no error; returns [dmErrNotValidRecord](#) or [dmErrWriteOutOfBounds](#) if an error occurred.

# Application-Defined Functions

## DmComparF

<b>Purpose</b>	Compares two records in a database.
<b>Declared In</b>	DataMgr.h
<b>Prototype</b>	<pre>typedef Int16 DmComparF (void *rec1, void *rec2, Int16 other, SortRecordInfoPtr rec1SortInfo, SortRecordInfoPtr rec2SortInfo, MemHandle appInfoH)</pre>
<b>Parameters</b>	<p>-&gt; rec1, rec2      Pointers to the two records to compare.</p> <p>-&gt; other            Any other custom information you want passed to the comparison function. This parameter is often used to indicate a sort direction (ascending or descending).</p> <p>-&gt; rec1SortInfo, rec2SortInfo Pointers to <a href="#">SortRecordInfoType</a> structures that specify unique sorting information for the two records.</p> <p>-&gt; appInfoH        A handle to the database's application info block.</p>
<b>Result</b>	Returns: <ul style="list-style-type: none"><li>• 0 if rec1 = rec2.</li><li>• &lt; 0 if rec1 &lt; rec2.</li><li>• &gt; 0 if rec1 &gt; rec2.</li></ul>
<b>Comments</b>	This function is used to sort the records in a database. It is specifically called by <a href="#">DmFindSortPosition</a> , <a href="#">DmInsertionSort</a> , and <a href="#">DmQuickSort</a> .
<b>Compatibility</b>	The DmComparF prototype changed in Palm OS version 2.0. Previously, the prototype only defined the first three parameters.

As a rule, the change in the number of arguments from three to six doesn't cause problems when a 1.0 application is run on a 2.0 device because the system only pulls the arguments from the stack that are there.

Keep in mind, however, that some optimized applications built with tools other than Metrowerks CodeWarrior for Palm OS may have problems as a result of the change in arguments when running on a 2.0 or later device.

## **Data and Resource Manager**

### *Application-Defined Functions*

---

# Error Manager

---

This chapter provides reference material for the error manager. The error manager API is declared in the header files `ErrorMgr.h` and `ErrorBase.h`. This chapter covers:

- [ERROR\\_CHECK\\_LEVEL Define](#)
- [Error Manager Data Structures](#)
- [Error Manager Functions](#)

For more information on the error manager, see the chapter “[Debugging Strategies](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## ERROR\_CHECK\_LEVEL Define

The error manager uses the compiler define `ERROR_CHECK_LEVEL` to control the level of error messages displayed. You can set the value of the compiler define to control which level of error checking and display is compiled into the application. Three levels of error checking are supported: none, partial, and full.

If you set <code>ERR_CHECK_LEVEL</code> to...	The compiler...
<code>ERROR_CHECK_NONE</code> (0)	Doesn’t compile in any error calls.
<code>ERROR_CHECK_PARTIAL</code> (1)	Compiles in only <code>ErrDisplay</code> and <code>ErrFatalDisplayIf</code> calls.
<code>ERROR_CHECK_FULL</code> (2)	Compiles in all three calls.

## Error Manager Data Structures

### ErrExceptionType

An `ErrExceptionType` structure is created for each `ErrTry` and `ErrCatch` block. At any point in the program, there is a linked list of these structures. An `ErrExceptionType` structure stores information about the state of the machine (register values) at the start of the `ErrTry` block.

```
typedef struct ErrExceptionType {
    struct ErrExceptionType *nextP;
    ErrJumpBuf state;
    Int32 err;
} ErrExceptionType;
typedef ErrExceptionType *ErrExceptionPtr;
```

#### Field Descriptions

`nextP` Next `ErrExceptionType` structure in the linked list.  
`state` Storage for `setjmp/longjmp`.  
`err` Error code.

## Error Manager Functions

### ErrAlert

<b>Purpose</b>	Macro that displays an alert dialog for runtime errors.
<b>Declared In</b>	<code>ErrorBase.h</code>
<b>Prototype</b>	<code>ErrAlert (err)</code>
<b>Parameters</b>	<code>-&gt; err</code> An error code (as type <code>Err</code> ).
<b>Result</b>	Returns 0, which indicates that the OK button has been clicked to dismiss the dialog.

**Comments** This macro is intended for use by applications that are likely to receive runtime errors when the application itself is not at fault. For example, a networking application might use it to display an alert if the remote server cannot be found.

The error message displayed on the dialog is stored in a 'tSTL' resource. A 'tSTL' resource contains a list of strings that can be looked up by index. The `err` parameter is used as the index into this list.

To use application-defined error codes in `ErrAlert`, make sure that all of your error codes are greater than or equal to `appErrorClass`. This way, the error manager looks up the code in the application's 'tSTL' resource number 0. All other error codes are taken from 'tSTL' resource stored in the system.

**Compatibility** Implemented only if [3.2 New Feature Set](#) is present.

## ErrCatch

**Purpose** Macro that marks the end of an [ErrTry](#) block and the beginning of an `ErrCatch` block.

**Declared In** `ErrorBase.h`

**Prototype** `ErrCatch (theErr)`

**Parameters** `-> theErr` An exception code identifying the reason for the failure. This is the value supplied to the [ErrThrow](#) call that caused the jump to this `ErrCatch` block.

**Result** Returns nothing.

**Comments** `ErrCatch` can only be used in conjunction with [ErrTry](#) and `ErrEndCatch`. See the comments under `ErrTry` for usage instructions.

`ErrTry`, `ErrCatch` and `ErrThrow` are based on `setjmp` and `longjmp`. At the beginning of an `ErrTry` block, `setjmp` saves the

## Error Manager

### Error Manager Functions

---

machine registers. `ErrThrow` calls `longjmp`, which restores the registers and jumps to the beginning of the `ErrCatch` block. Therefore, any changes in the `ErrTry` block to variables stored in registers aren't retained when entering the `ErrCatch` block.

The solution is to declare variables that you want to use in both the `ErrTry` and `ErrCatch` blocks as "volatile". For example:

---

```
volatile long x = 1; // Declare volatile local variable
ErrTry {
    x = 100; // Set local variable in Try
    ErrThrow(-1);
}
ErrCatch(inErr) {
    if (x > 1) { // Use local variable in Catch
        SysBeep(1);
    }
} ErrEndCatch
```

---

If you have many local variables after the `ErrCatch` you may want to put the `ErrTry` and `ErrCatch` in a separate enclosing function.

## ErrDisplay

<b>Purpose</b>	Macro that displays an error alert if error checking is set to partial or full.
<b>Declared In</b>	<code>ErrorMgr.h</code>
<b>Prototype</b>	<code>ErrDisplay (msg)</code>
<b>Parameters</b>	-> <code>msg</code> Error message text as a string.
<b>Result</b>	No return value.
<b>Comments</b>	Call this macro to display an error message, source code filename, and line number. This macro is compiled into the code only if the compiler define <code>ERROR_CHECK_LEVEL</code> is set to 1 or 2 ( <code>ERROR_CHECK_PARTIAL</code> or <code>ERROR_CHECK_FULL</code> ).
<b>See Also</b>	<a href="#">ErrFatalDisplayIf</a> , <a href="#">ErrNonFatalDisplayIf</a>

## **ErrDisplayFileLineMsg**

- Purpose** Display a dialog with an error message. Do not allow the user to exit the dialog or continue.
- Declared In** `ErrorBase.h`
- Prototype**  
`void ErrDisplayFileLineMsg  
(const Char *const filename, UInt16 lineNo,  
const Char *const msg)`
- Parameters**
- > `filename`      Source code filename.
  - > `lineno`        Line number in the source code file.
  - > `msg`            Message to display.
- Result** Never returns.
- Comment** Called by [ErrFatalDisplayIf](#) and [ErrNonFatalDisplayIf](#). This function is useful when the application is already on the device and being tested by users.
- On Japanese systems, the system displays a generic message indicating that an error has occurred instead of displaying the English message.
- See Also** [ErrFatalDisplayIf](#), [ErrNonFatalDisplayIf](#), [ErrDisplay](#)

## **ErrEndCatch**

- Purpose** Macro that marks the end of an [ErrCatch](#) block.
- Declared In** `ErrorBase.h`
- Prototype** `ErrEndCatch`
- Parameters** None.
- Result** Returns nothing.

## Error Manager

### Error Manager Functions

---

**Comments** `ErrEndCatch` can only be used in conjunction with [ErrTry](#) and `ErrCatch`. See the comments under `ErrTry` for usage instructions.

## ErrExceptionList

**Purpose** Return the address of the pointer to the first [ErrExceptionType](#) structure in the linked list of exception structures.

**Declared In** `ErrorBase.h`

**Prototype** `MemPtr *ErrExceptionList (void)`

**Parameters** None.

**Result** Returns the address of the pointer to the first `ErrExceptionType` structure linked into the exception list.

**Comments** This function is used by the `ErrTry` and `ErrCatch` macros as well as the [ErrThrow](#) function in order to find the exception list.

When called from an application, this routine returns the application's exception list.

## ErrFatalDisplayIf

**Purpose** Macro that displays an error alert dialog if `condition` is `true` and error checking is set to partial or full.

**Declared In** `ErrorMgr.h`

**Prototype** `ErrFatalDisplayIf (condition, msg)`

**Parameters**

-> <code>condition</code>	A boolean value. If <code>true</code> , display the error.
-> <code>msg</code>	Error message text as a string.

**Result** No return value.

**Comments** Call this macro to display a fatal error message, source code filename, and line number. The alert is displayed only if `condition` is `true`. The dialog is cleared only when the user resets the system by responding to the dialog.

This macro is compiled into the code if the compiler define `ERROR_CHECK_LEVEL` is set to 1 or 2 (`ERROR_CHECK_PARTIAL` or `ERROR_CHECK_FULL`).

**See Also** [ErrNonFatalDisplayIf](#), [ErrDisplay](#),

## **ErrNonFatalDisplayIf**

**Purpose** Macro that displays an error alert dialog if `condition` is `true` and error checking is set to full.

**Declared In** `ErrorMgr.h`

**Prototype** `ErrNonFatalDisplayIf (condition, msg)`

**Parameters**  
-> `condition`      A boolean value. If `true`, display the error.  
-> `msg`              Error message text as a string.

**Result** No return value.

**Comments** Call this macro to display a nonfatal error message, source code filename, and line number. The alert is displayed only if `condition` is `true`. The alert dialog is cleared when the user selects to continue (or resets the system).

This macro is compiled into the code only if the compiler define `ERROR_CHECK_LEVEL` is set to 2 (`ERROR_CHECK_FULL`).

**See Also** [ErrFatalDisplayIf](#), [ErrDisplay](#)

## **ErrThrow**

- Purpose** Cause a jump to the nearest Catch block.
- Declared In** `ErrorBase.h`
- Prototype** `void ErrThrow (Int32 err)`
- Parameters** `-> err` Error code.
- Result** Never returns.
- Comments** Use the macros `ErrTry`, `ErrCatch`, and `ErrEndCatch` in conjunction with this function.
- See Also** [ErrFatalDisplayIf](#), [ErrNonFatalDisplayIf](#), [ErrDisplay](#)

## **ErrTry**

- Purpose** Macro that marks the beginning of a try/catch block.
- Declared In** `ErrorBase.h`
- Prototype** `ErrTry`
- Parameters** None.
- Result** Returns nothing.
- Comments** An exception raised by a call to [ErrThrow](#)—even from within a nested subroutine—causes program execution to switch to the beginning of the [ErrCatch](#) block. If the end of the block enclosed by `ErrTry` is encountered without a call to `ErrThrow`, execution jumps to the line of code following the [ErrEndCatch](#) macro. See “[The Try-and-Catch Mechanism](#)” on page 377 of the *Palm OS Programmer’s Companion*, vol. I for a more thorough description of how this mechanism works.

**Example** You must structure your code exactly as shown here. You can't use `ErrTry` without `ErrCatch` and `ErrEndCatch`, or vice versa.

---

```
ErrTry {
    // Do something which may fail. Call ErrThrow to signal
    // failure and force a jump to the following ErrCatch
    // block.
}
ErrCatch(inErr) {
    // Recover or cleanup after a failure in the above ErrTry
    // block. "inErr" is an exception code identifying the
    // reason for the failure.

    // Call ErrThrow if you want to jump out to the next
    // ErrCatch block.

    // The code in this block doesn't execute if the above
    // ErrTry block completes without a call to ErrThrow.
} ErrEndCatch
```

---

## **Error Manager**

### *Error Manager Functions*

---

# Expansion Manager

---

This chapter provides the following information about the Expansion Manager:

- [Expansion Manager Data Structures](#)
- [Expansion Manager Constants](#)
- [Expansion Manager Functions](#)

The header file `ExpansionMgr.h` declares the Expansion Manager API. For more information on the Expansion Manager, see [Chapter Z, “Expansion,”](#) in *Palm OS Programmer’s Companion*, vol. I.

Note that the Expansion Manager is an optional system extension; the functions described in this chapter are implemented only if the [Expansion Manager Feature Set](#) is present.

## Expansion Manager Data Structures

### ExpCardInfoType

The `ExpCardInfoType` declaration defines a structure that is passed to [ExpCardInfo](#). This structure is used to determine the characteristics of the card loaded in the slot. It is initialized by the underlying slot driver with the following information.

```
typedef struct ExpCardInfoTag {
    UInt32 capabilityFlags;
    Char
        manufacturerStr[expCardInfoStringMaxLen+1];
    Char productStr[expCardInfoStringMaxLen+1];
    Char
        deviceClassStr[expCardInfoStringMaxLen+1];
    Char
        deviceUniqueIDStr[expCardInfoStringMaxLen+1];
} ExpCardInfoType, *ExpCardInfoPtr;
```

## Expansion Manager

### Expansion Manager Constants

---

#### Field Descriptions

<code>capabilityFlags</code>	Describes the capabilities of the card. The following flags are currently supported: <ul style="list-style-type: none"><li>• <code>expCapabilityHasStorage</code> indicates that the card supports reading and (possibly) writing.</li><li>• <code>expCapabilityReadOnly</code> indicates that the card is read only.</li><li>• <code>expCapabilitySerial</code> indicates that the card supports a simple serial interface.</li></ul>
<code>manufacturerStr</code>	Names the manufacturer of the card. For example “Palm” or “Motorola”.
<code>productStr</code>	Name of the product. For example “SafeBackup 32MB”.
<code>deviceClassStr</code>	Describes the type of card, for example, “Backup” or “Ethernet”.
<code>deviceUniqueIDStr</code>	Unique identifier for the product. A serial number for example. This value is set to the empty string if no identifier exists.

## Expansion Manager Constants

### Error Codes

The Expansion Manager defines the following error codes:

---

Constant	Description
<code>expErrUnsupportedOperation</code>	The operation is unsupported or undefined.
<code>expErrNotEnoughPower</code>	The required power is not available.
<code>expErrCardNotPresent</code>	There is no card present in the given slot.

---

<b>Constant</b>	<b>Description</b>
<code>expErrInvalidSlotRefNum</code>	The slot reference number is not valid.
<code>expErrSlotDeallocated</code>	The slot reference number is within the valid range, but the slot has been deallocated.
<code>expErrCardNoSectorReadWrite</code>	The card does not support the slot driver block read/write API.
<code>expErrCardReadOnly</code>	The card supports the slot driver block read/write API but the card is read only.
<code>expErrCardBadSector</code>	The card supports the slot driver block read/write API but the sector is bad.
<code>expErrCardProtectedSector</code>	The card supports the slot driver block read/write API but the sector is protected.
<code>expErrNotOpen</code>	The slot driver library has not been opened.
<code>expErrStillOpen</code>	The slot driver library is still open; it may have been opened more than once.
<code>expErrUnimplemented</code>	The call is unimplemented.
<code>expErrEnumerationEmpty</code>	There are no values remaining to enumerate.
<code>expErrIncompatibleAPIVer</code>	The API version of the underlying slot driver is not supported by this version of Expansion Manager.

---

## Defined Media Types

The following media types are defined by the Expansion Manager. These media types are used with the function [VFSVolumeInfo](#) in the `VolumeInfoType.mediaType` field. The media type is also passed as a parameter to the [VFSRegisterDefaultDirectory](#) and [VFSUnregisterDefaultDirectory](#) functions.

## Expansion Manager

### Expansion Manager Functions

---

Constant	Value	Description
<code>expMediaType_Any</code>	'wild'	Matches all media types when looking up a default directory
<code>expMediaType_MemoryStick</code>	'mstk'	Memory stick
<code>expMediaType_CompactFlash</code>	'cfsh'	Compact Flash
<code>expMediaType_SecureDigital</code>	'sdig'	Secure Digital
<code>expMediaType_MultiMediaCard</code>	'mmcd'	MultiMedia Card
<code>expMediaType_SmartMedia</code>	'smed'	SmartMedia
<code>expMediaType_RAMDisk</code>	'ramd'	A RAM disk based media
<code>expMediaType_PoserHost</code>	'pose'	Host file system emulated by the Palm OS <sup>®</sup> Emulator
<code>expMediaType_MacSim</code>	'PSim'	Host file system emulated by the Mac Simulator

---

## Expansion Manager Functions

### ExpCardGetSerialPort

- Purpose** Get a card's serial port creator ID for use in serial access.
- Declared In** `ExpansionMgr.h`
- Prototype** `Err ExpCardGetSerialPort(UInt16 slotRefNum, UInt32 *portP)`
- Parameters** `-> slotRefNum` Slot number of slot to check.

<- portP            Pointer to UInt32 into which the serial port creator ID is stored.

**Result**            Returns the following result codes:

errNone              No error

expErrInvalidSlotRefNum  
                      The specified slot number is invalid.

expErrSlotDeallocated  
                      The specified slot number is within the valid range but has been deallocated.

**Compatibility**    Implemented only if the [Expansion Manager Feature Set](#) is present.

**See Also**            [ExpCardInfo](#)

## **ExpCardInfo**

**Purpose**             Obtains information about a card in a given slot.

**Declared In**        ExpansionMgr.h

**Prototype**          Err ExpCardInfo(UInt16 slotRefNum,  
ExpCardInfoType \*infoP)

**Parameters**        -> slotRefNum    Slot number.  
                      <- infoP            Pointer to [ExpCardInfoType](#) structure.

**Result**             Returns one of the following result codes:

errNone              No error

expErrCardNotPresent  
                      There is no card present in the specified slot.

expErrInvalidSlotRefNum  
                      The slot number is invalid.

## Expansion Manager

### Expansion Manager Functions

---

`expErrSlotDeallocated`

The slot number is within the valid range but has been deallocated.

**Comments** This function returns information about a card, including whether the card supports secondary storage or is strictly read-only, by filling in the `ExpCardInfoType` structure's fields.

**Compatibility** Implemented only if the [Expansion Manager Feature Set](#) is present.

**See Also** [ExpCardGetSerialPort](#), [ExpCardPresent](#), [ExpSlotEnumerate](#)

## ExpCardPresent

**Purpose** Determines if a card is present in the given slot.

**Declared In** `ExpansionMgr.h`

**Prototype** `Err ExpCardPresent (UInt16 slotRefNum)`

**Parameters** `-> slotRefNum` Slot number.

**Result** Returns the following result codes:

`errNone` A card is present in the specified slot.

`expErrCardNotPresent`  
There is no card present in the specified slot.

`expErrInvalidSlotRefNum`  
The specified slot number is not valid.

`expErrSlotDeallocated`  
The specified slot number is within the valid range but has been deallocated.

- Comments** The Expansion Manager passes the call through to the appropriate slot driver.
- Compatibility** Implemented only if the [Expansion Manager Feature Set](#) is present.
- See Also** [ExpCardInfo](#), [ExpSlotEnumerate](#)

## ExpSlotDriverInstall

- Purpose** Installs and initializes a slot driver shared library into the system table.
- Declared In** `ExpansionMgr.h`
- Prototype**  
`Err ExpSlotDriverInstall (UInt32 dbCreator,  
UInt16 *slotLibRefNumP)`
- Parameters**
- > `dbCreator` Database creator code of the slot driver library to be installed.
  - > `slotLibRefNumP` Pointer to variable for returning the library reference number (on failure, `sysInvalidRefNum` is returned in this variable).

**Result** Returns `errNone` if the slot driver is installed correctly. Because this function uses [SysLibInstall](#) to install the slot driver shared library, `ExpSlotDriverInstall` may return any of the error codes that `SysLibInstall` returns, including `sysErrLibNotFound`, `sysErrNoFreeRAM`, and `sysErrNoFreeLibSlots`. It may also return any error code returned by `SlotOpen`, the implementation of which is specific to a given device manufacturer.

- Comments** This function is not typically called by applications but can be used to load additional slot drivers after the device has booted. It is called internally by the Expansion Manager to install a slot driver shared library into the library table and initialize it for use. Once installed,

## Expansion Manager

### Expansion Manager Functions

---

the `slotLibRefNum` can be used by other functions to refer to the library.

**Compatibility** Implemented only if the [Expansion Manager Feature Set](#) is present.

**See Also** [ExpSlotDriverRemove](#), [ExpSlotLibFind](#)

## ExpSlotDriverRemove

**Purpose** Closes and remove a slot driver shared library from the system table.

**Declared In** `ExpansionMgr.h`

**Prototype** `Err ExpSlotDriverRemove (UInt16 slotLibRefNum)`

**Parameters** `-> slotLibRefNum`  
Slot driver shared library reference number.

**Result** Returns `errNone`.

**Comments** This function is not typically called by applications but can be used to unload slot drivers associated with external slots. It is called internally by the Expansion Manager to remove the shared library from the system table, and, if appropriate, release the slot allocated to the given `slotLibRefNum`. Prior to removing the slot driver, it unmounts any volumes associated with the slot.

**Compatibility** Implemented only if the [Expansion Manager Feature Set](#) is present.

**See Also** [ExpSlotDriverInstall](#), [ExpSlotLibFind](#), [SysLibRemove](#)

## ExpSlotEnumerate

- Purpose** Iterates through valid slot numbers.
- Declared In** `ExpansionMgr.h`
- Prototype** `Err ExpSlotEnumerate(UInt16 *slotRefNumP, UInt32 *slotIteratorP)`
- Parameters**
- `<- slotRefNumP` Reference number of the currently-enumerated slot.
  - `-> slotIteratorP` Pointer to the index of the last entry enumerated. For the first iteration, initialize this parameter to the constant `expIteratorStart`. Upon return this references the next entry in the directory. If this is the last entry, this parameter is set to `expIteratorStop`.
- Result** Returns one of the following result codes:
- `errNone` The slot reference number indicated by `slotRefNumP` is valid.
  - `expErrEnumerationEmpty` There are no slots left to enumerate. `slotRefNumP` is set to the slot number of the currently enumerated slot or `invalidSlotRefNum` if there are no slots.
- Comments** This function iterates through the device's slots. The first time this function is called, set `*slotIteratorP` to `expIteratorStart` to find the initial slot. Once set this value is changed with each subsequent call to this function until it reaches the maximum number of slots, at which point `ExpSlotEnumerate` sets `*slotIteratorP` to `expIteratorStop`.
- Example** The following is an example of how `ExpSlotEnumerate` should be used:

## Expansion Manager

### Expansion Manager Functions

---

---

```
UInt16 slotRefNum;
UInt32 slotIterator = expIteratorStart;
while (slotIterator != expIteratorStop) {
    if ((err = ExpSlotEnumerate(&slotRefNum,
        &slotIterator)) == errNone) {
        // do something with the slotRefNum
    } else {
        // handle error (by breaking out of the
        // loop, most likely)
    }
}
```

---

**Compatibility** Implemented only if the [Expansion Manager Feature Set](#) is present.

**See Also** [ExpCardInfo](#), [ExpCardPresent](#), [ExpSlotDriverRemove](#)

## ExpSlotLibFind

**Purpose** Retrieves the slot driver library reference number for the driver that controls the specified slot.

**Declared In** ExpansionMgr.h

**Prototype** Err ExpSlotLibFind(UInt16 slotRefNum,  
UInt16 \*slotLibRefNum)

**Parameters** -> slotRefNum Slot number.  
<- slotLibRefNum  
Pointer to the reference number for the slot driver library allocated to the given slot.

**Result** Returns the following result codes:

errNone	No error.
expErrInvalidSlotRefNum	The slot number is invalid.

`expErrSlotDeallocated`

The slot number is within the valid range but has been deallocated.

**Comments** This function returns the reference number to the slot driver library loaded for the given `slotRefNum`. This function is used when making calls directly to the slot driver library.

**Compatibility** Implemented only if the [Expansion Manager Feature Set](#) is present.

**See Also** [ExpSlotDriverInstall](#), [ExpSlotDriverRemove](#)

## **Expansion Manager**

*Expansion Manager Functions*

---

# Feature Manager

---

This chapter provides reference material for the feature manager. The feature manager API is declared in the header file `FeatureMgr.h`.

For more information on the feature manager, see the section “[Features](#)” in the *Palm OS Programmer’s Companion*, vol. I.

To learn how to use the predefined Palm OS® features to test for the existence of certain OS features, see the “[Compatibility Guide](#)” appendix.

## Feature Manager Functions

### FtrGet

<b>Purpose</b>	Get a feature.
<b>Declared In</b>	<code>FeatureMgr.h</code>
<b>Prototype</b>	<code>Err FtrGet (UInt32 creator, UInt16 featureNum, UInt32 *valueP)</code>
<b>Parameters</b>	<p>-&gt; <code>creator</code> Creator ID, which must be registered with PalmSource, Inc. This is usually the same as the creator ID for the application that owns this feature.</p> <p>-&gt; <code>featureNum</code> Feature number of the feature.</p> <p>&lt;- <code>valueP</code> Value of the feature is returned here.</p>
<b>Result</b>	Returns 0 if no error, or <code>ftrErrNoSuchFeature</code> if the specified feature number doesn’t exist for the specified creator.

## Feature Manager

### Feature Manager Functions

---

**Comments** The value of the feature is application-dependent.

**See Also** [FtrSet](#)

## FtrGetByIndex

**Purpose** Get a feature by index.

**Declared In** `FeatureMgr.h`

**Prototype** `Err FtrGetByIndex (UInt16 index, Boolean romTable, UInt32 *creatorP, UInt16 *numP, UInt32 *valueP)`

**Parameters**

-> index	Index of feature.
-> romTable	If true, index into ROM table; otherwise, index into RAM table.
<- creatorP	Feature creator is returned here.
<- numP	Feature number is returned here.
<- valueP	Feature value is returned here.

**Result** Returns 0 if no error, or `ftrErrNoSuchFeature` if the index is out of range.

**Comments** This function is intended for system use only. It is used by shell commands. Most applications don't need it.

Until the caller gets back `ftrErrNoSuchFeature`, it should pass indices for each table (ROM, RAM) starting at 0 and incrementing. Note that in Palm OS 3.1 and higher, the RAM feature table serves the entire system. At system startup, the values in the ROM feature table are copied into the RAM feature table.

## **FtrPtrFree**

<b>Purpose</b>	Release memory previous allocated with <a href="#">FtrPtrNew</a> .
<b>Declared In</b>	FeatureMgr.h
<b>Prototype</b>	<code>Err FtrPtrFree (UInt32 creator, UInt16 featureNum)</code>
<b>Parameters</b>	-> creator      The creator ID for the feature. -> featureNum    Feature number of the feature.
<b>Result</b>	Returns 0 if no error, or <code>ftrErrNoSuchFeature</code> if an error occurs.
<b>Comments</b>	This function unregisters the feature before freeing the memory associated with it.
<b>Compatibility</b>	Implemented only if <a href="#">3.1 New Feature Set</a> is present.

## **FtrPtrNew**

<b>Purpose</b>	Allocate feature memory.
<b>Declared In</b>	FeatureMgr.h
<b>Prototype</b>	<code>Err FtrPtrNew (UInt32 creator, UInt16 featureNum, UInt32 size, void **newPtrP)</code>
<b>Parameters</b>	-> creator      Creator ID, which must be registered with PalmSource, Inc. This is usually the same as the creator ID for the application that owns this feature. -> featureNum    Feature number of the feature. -> size          Size in bytes of the temporary memory to allocate. The maximum chunk size is 64K.

## Feature Manager

### Feature Manager Functions

---

`<- newPtrP`      Pointer to the memory chunk is returned here.

**Result**      Returns 0 if no error, `memErrInvalidParam` if the value of `size` is 0, or `memErrNotEnoughSpace` if there is not enough space to allocate a chunk of the specified size.

**Comments**      This function allocates a chunk of memory and stores a pointer to that chunk in the feature table. The same pointer is returned in `newPtrP`. The memory chunk remains allocated and locked until the next system reset or until you free the chunk with [FtrPtrFree](#). `FtrPtrNew` is useful if you want quick, efficient access to data that persists from one invocation of the application to the next. `FtrPtrNew` stores values on the storage heap rather than the dynamic heap, where free space is often extremely limited. The disadvantage to using feature memory is that writing to storage memory is slower than writing to dynamic memory.

---

**NOTE:** Starting with Palm OS 3.5 `FtrPtrNew` allows allocating chunks larger than 64k. Do keep in mind standard issues with allocating large chunks of memory: there might not be enough contiguous space, and it can impact system performance.

---

You can obtain the pointer to the chunk using [FtrGet](#). To write to the chunk, you **must** use [DmWrite](#) because the chunk is in the storage heap, not the dynamic heap.

For example, if you allocate a memory chunk in this way:

```
FtrPtrNew(appCreator,
          myFtrMemFtr, 32, &ftrMem);
```

You can later access that memory and write to it using the following:

```
void* data;
if (!FtrGet(appCreator,
            myFtrMemFtr, (UInt32*)&data))
    DmWrite(data, 0, &someVal, sizeof(someVal));
```

**Compatibility**      Implemented only if [3.1 New Feature Set](#) is present.

**See Also**      [FtrPtrResize](#)

## FtrPtrResize

<b>Purpose</b>	Resize feature memory.								
<b>Declared In</b>	FeatureMgr.h								
<b>Prototype</b>	<pre>Err FtrPtrResize (UInt32 creator,                 UInt16 featureNum, UInt32 newSize,                 void **newPtrP)</pre>								
<b>Parameters</b>	<table><tr><td>-&gt; creator</td><td>The creator ID for the feature.</td></tr><tr><td>-&gt; featureNum</td><td>Feature number of the feature.</td></tr><tr><td>-&gt; newSize</td><td>New size in bytes for the chunk.</td></tr><tr><td>&lt;- newPtrP</td><td>Pointer to the memory chunk is returned here.</td></tr></table>	-> creator	The creator ID for the feature.	-> featureNum	Feature number of the feature.	-> newSize	New size in bytes for the chunk.	<- newPtrP	Pointer to the memory chunk is returned here.
-> creator	The creator ID for the feature.								
-> featureNum	Feature number of the feature.								
-> newSize	New size in bytes for the chunk.								
<- newPtrP	Pointer to the memory chunk is returned here.								
<b>Result</b>	Returns 0 if no error, or <code>ftrErrNoSuchFeature</code> if the specified feature number doesn't exist for the specified creator, <code>memErrInvalidParam</code> if <code>newSize</code> is 0, or <code>memErrNotEnoughSpace</code> if there's not enough free space available to allocate a chunk of that size.								
<b>Comments</b>	<p>Use this function to resize a chunk of memory previously allocated by <a href="#">FtrPtrNew</a>.</p> <p>This function may move the chunk to a new location in order to resize it, so it is important to use the pointer returned by this function when accessing the memory chunk. The pointer in the feature table is automatically updated to be the same as the pointer returned by this function.</p> <p>If this function fails, the old memory pointer still exists and its data is unchanged.</p>								
<b>Compatibility</b>	Implemented only if <a href="#">3.1 New Feature Set</a> is present.								
<b>See Also</b>	<a href="#">MemHandleResize</a>								

## Feature Manager

### Feature Manager Functions

---

#### FtrSet

<b>Purpose</b>	Set a feature.						
<b>Declared In</b>	FeatureMgr.h						
<b>Prototype</b>	Err FtrSet (UInt32 creator, UInt16 featureNum, UInt32 newValue)						
<b>Parameters</b>	<table><tr><td>-&gt; creator</td><td>Creator ID, which must be registered with PalmSource, Inc. This is usually the same as the creator ID for the application that owns this feature.</td></tr><tr><td>-&gt; featureNum</td><td>Feature number for this feature.</td></tr><tr><td>-&gt; newValue</td><td>New value.</td></tr></table>	-> creator	Creator ID, which must be registered with PalmSource, Inc. This is usually the same as the creator ID for the application that owns this feature.	-> featureNum	Feature number for this feature.	-> newValue	New value.
-> creator	Creator ID, which must be registered with PalmSource, Inc. This is usually the same as the creator ID for the application that owns this feature.						
-> featureNum	Feature number for this feature.						
-> newValue	New value.						
<b>Result</b>	Returns 0 if no error, or memErrNotEnoughSpace if the feature table must be resized to add a new feature and no space is available.						
<b>Comments</b>	<p>The value of the feature is application-dependent.</p> <p>A feature that you define in this manner remains defined until the next system reset or until you explicitly undefine the feature with <a href="#">FtrUnregister</a>.</p>						
<b>See Also</b>	<a href="#">FtrGet</a> , <a href="#">FtrPtrNew</a>						

#### FtrUnregister

<b>Purpose</b>	Unregister a feature.		
<b>Declared In</b>	FeatureMgr.h		
<b>Prototype</b>	Err FtrUnregister (UInt32 creator, UInt16 featureNum)		
<b>Parameters</b>	<table><tr><td>-&gt; creator</td><td>Creator ID for the feature.</td></tr></table>	-> creator	Creator ID for the feature.
-> creator	Creator ID for the feature.		

-> featureNum Feature number of the feature.

**Result** Returns 0 if no error, or `ftErrNoSuchFeature` if the specified feature number doesn't exist for the specified creator.

## **Feature Manager**

### *Feature Manager Functions*

---

# File Streaming

---

This chapter provides reference material for the file streaming API.

- [File Streaming Constants](#)
- [File Streaming Functions](#)
- [File Streaming Error Codes](#)

The header file `FileStream.h` declares the API that this chapter describes. For more information on file streaming, see the chapter “[Files and Databases](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## File Streaming Constants

### Primary Open Mode Constants

This section lists constants passed in the `openMode` parameter to the [FileOpen](#) function. These constants specify the mode in which a file stream is opened.

For each file stream, you must pass to the [FileOpen](#) function only one of the primary mode selectors listed.

#### Constant Values

<code>fileModeReadOnly</code>	Open for read-only access
<code>fileModeReadWrite</code>	Open/create for read/write access, discarding any previous version of stream
<code>fileModeUpdate</code>	Open/create for read/write, preserving previous version of stream if it exists
<code>fileModeAppend</code>	Open/create for read/write, always writing to the end of the stream

## Secondary Open Mode Constants

You can use the `|` operator (bitwise inclusive OR) to append to a primary mode selector one or more of the secondary mode selectors listed below.

<code>fileModeDontOverwrite</code>	Prevents <code>fileModeReadWrite</code> from discarding an existing stream having the same name; may only be specified together with <code>fileModeReadWrite</code>
<code>fileModeLeaveOpen</code>	Leave stream open when application quits. Most applications should not use this option.
<code>fileModeExclusive</code>	No other application can open the stream until the application that opened it in this mode closes it.
<code>fileModeAnyTypeCreator</code>	Accept any type/creator when opening or replacing an existing stream. Normally, the <a href="#">FileOpen</a> function opens only streams having the specified creator and type. Setting this option enables the <code>FileOpen</code> function to open streams having a type or creator other than those specified.
<code>fileModeTemporary</code>	Delete the stream automatically when it is closed. For more information, see Comment section of <a href="#">FileOpen</a> function description.

## File Streaming Functions

### FileClearerr

- Purpose** Clear I/O error status, end of file error status, and last error.
- Declared In** FileStream.h
- Prototype** Err FileClearerr (FileHand stream)
- Parameters** --> stream          Handle to open stream.
- Result** 0 if no error, or a fileErr code if an error occurs. See the section "[File Streaming Error Codes](#)" for more information.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.
- See Also** [FileGetLastError](#), [FileRewind](#)

### FileClose

- Purpose** Close the file stream and destroy its handle. If the stream was opened with fileModeTemporary, it is deleted upon closing.
- Declared In** FileStream.h
- Prototype** Err FileClose (FileHand stream)
- Parameters** --> stream          Handle to open stream.
- Result** 0 if no error, or a fileErr code if an error occurs. See the section "[File Streaming Error Codes](#)" for more information.
- Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## **FileControl**

<b>Purpose</b>	Perform the operation specified by the <code>op</code> parameter on the <code>stream</code> file stream.								
<b>Declared In</b>	<code>FileStream.h</code>								
<b>Prototype</b>	<code>Err FileControl (FileOpEnum op, FileHand stream, void *valueP, Int32 *valueLenP)</code>								
<b>Parameters</b>	<table><tr><td><code>op</code></td><td>The operation to perform, and its associated formal parameters. See the Comments section for a list of possible values.</td></tr><tr><td><code>--&gt; stream</code></td><td>Open stream handle if required for file stream operation.</td></tr><tr><td><code>&lt;--&gt; valueP</code></td><td>Pointer to value or buffer, as required. This parameter is defined by the selector passed as the value of the <code>op</code> parameter. For details, see the Comments section.</td></tr><tr><td><code>&lt;--&gt; valueLenP</code></td><td>Pointer to value or buffer, as required. This parameter is defined by the selector passed as the value of the <code>op</code> parameter. For details, see the Comments section.</td></tr></table>	<code>op</code>	The operation to perform, and its associated formal parameters. See the Comments section for a list of possible values.	<code>--&gt; stream</code>	Open stream handle if required for file stream operation.	<code>&lt;--&gt; valueP</code>	Pointer to value or buffer, as required. This parameter is defined by the selector passed as the value of the <code>op</code> parameter. For details, see the Comments section.	<code>&lt;--&gt; valueLenP</code>	Pointer to value or buffer, as required. This parameter is defined by the selector passed as the value of the <code>op</code> parameter. For details, see the Comments section.
<code>op</code>	The operation to perform, and its associated formal parameters. See the Comments section for a list of possible values.								
<code>--&gt; stream</code>	Open stream handle if required for file stream operation.								
<code>&lt;--&gt; valueP</code>	Pointer to value or buffer, as required. This parameter is defined by the selector passed as the value of the <code>op</code> parameter. For details, see the Comments section.								
<code>&lt;--&gt; valueLenP</code>	Pointer to value or buffer, as required. This parameter is defined by the selector passed as the value of the <code>op</code> parameter. For details, see the Comments section.								
<b>Result</b>	Returns either a value defined by the selector passed as the argument to the <code>op</code> parameter, or an error code resulting from the requested operation. For details, see the Comments section.								
<b>Comments</b>	Normally, you do not call the <a href="#">FileControl</a> function yourself; it is called for you by most of the other file streaming functions and macros to perform common file streaming operations. You can call <a href="#">FileControl</a> yourself to enable specialized read modes.								

<code>fileOpNone</code>	No-op.
<code>fileOpDestructiveReadMode</code>	<p>Enter destructive read mode, and rewind stream to its beginning. Once in this mode, there is no turning back: stream's contents after closing (or crash) are undefined.</p> <p>Destructive read mode deletes blocks as data are read, thus freeing storage automatically. Once in destructive read mode, you cannot re-use the file stream—the contents of the stream are undefined after it is closed or after a crash.</p> <p>Writing to files opened without write access or those that are in destructive read state is not allowed; thus, you cannot call the <a href="#">FileWrite</a>, <a href="#">FileSeek</a>, or <a href="#">FileTruncate</a> functions on a stream that is in destructive read mode. One exception to this rule applies to streams that were opened in “write + append” mode and then switched into destructive read state. In this case, the <a href="#">FileWrite</a> function can append data to the stream, but it also preserves the current stream position so that subsequent reads pick up where they left off (you can think of this as a pseudo-pipe).</p> <p>ARGUMENTS: stream = open stream handle valueP = NULL valueLenP = NULL</p> <p>RETURNS: zero on success; fileErr... on error</p>
<code>fileOpGetEOFStatus</code>	Get end-of-file status (like C runtime's <code>feof</code> ) ( <code>err = fileErrEOF</code> ). Indicates end of file condition. Use <a href="#">FileClearerr</a> to clear this error status.

## File Streaming

### File Streaming Functions

---

	<p>ARGUMENTS: stream = open stream handle valueP = NULL valueLenP = NULL</p> <p>RETURNS: zero if not end of file; non-zero if end of file</p>
<code>fileOpGetLastError</code>	<p>Get error code from last operation on stream, and clear the last error code value. Doesn't change status of EOF or I/O errors —use <a href="#">FileClearerr</a> to reset all error codes.</p> <p>ARGUMENTS: stream = open stream handle valueP = NULL valueLenP = NULL</p> <p>RETURNS: Error code from last file stream operation</p>
<code>fileOpClearError</code>	<p>Clear I/O and EOF error status and last error.</p> <p>ARGUMENTS: stream = open stream handle valueP = NULL valueLenP = NULL</p> <p>RETURNS: zero on success; fileErr... on error</p>
<code>fileOpGetIOErrorStatus</code>	<p>Get I/O error status (like C runtime's <code>ferror</code>). Use <a href="#">FileClearerr</a> to clear this error status.</p> <p>ARGUMENTS: stream = open stream handle valueP = NULL valueLenP = NULL</p> <p>RETURNS: zero if not I/O error; non-zero if I/O error is pending.</p>

<code>fileOpGetCreatedStatus</code>	<p>Find out whether file was created by <a href="#">FileOpen</a> function</p> <p><b>ARGUMENTS:</b> <code>stream</code> = open stream handle <code>valueP</code> = Pointer to Boolean <code>valueLenP</code> = Pointer to Int32 variable set to <code>sizeof(Boolean)</code></p> <p><b>RETURNS:</b> zero on success; <code>fileErr...</code> on error. The Boolean variable will be set to non-zero if the file was created.</p>
<code>fileOpGetOpenDbRef</code>	<p>Get the open database reference (handle) of the underlying database that implements the stream (NULL if none); this is needed for performing Palm OS-specific operations on the underlying database, such as changing or getting creator and type, version, backup/reset bits, and so on.</p> <p><b>ARGUMENTS:</b> <code>stream</code> = open stream handle <code>valueP</code> = Pointer to <code>DmOpenRef</code> variable <code>valueLenP</code> = Pointer to Int32 variable set to <code>sizeof(DmOpenRef)</code></p> <p><b>RETURNS:</b> zero on success; <code>fileErr...</code> on error. The <code>DmOpenRef</code> variable will be set to the file's open db reference that may be passed to Data Manager calls;</p> <p><b>WARNING:</b> Do not make any changes to the data of the underlying database -- doing so will corrupt the file stream.</p>
<code>fileOpFlush</code>	<p>Flush any cached data to storage.</p>

## File Streaming

### File Streaming Functions

---

#### ARGUMENTS:

stream = open stream handle

valueP = NULL

valueLenP = NULL

#### RETURNS:

zero on success; fileErr... on error;

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileClearerr](#), [FileEOF](#), [FileError](#), [FileFlush](#),  
[FileGetLastError](#), [FileRewind](#)

## FileDelete

**Purpose** Deletes the specified file stream from the specified card. Only a closed stream may be passed to this function.

**Declared In** FileStream.h

**Prototype** Err FileDelete (UInt16 cardNo, const Char \*nameP)

**Parameters**

cardNo	Card on which the file stream to delete resides. Currently, no Palm OS® devices support multiple cards, so this value must be 0.
nameP	String that is the name of the stream to delete.

**Result** 0 if no error, or a fileErr code if an error occurs. See the section "[File Streaming Error Codes](#)" for more information.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileOpen](#)

## FileDmRead

<b>Purpose</b>	A macro that reads data from a file stream into a chunk, record, or resource residing in a database.												
<b>Declared In</b>	FileStream.h												
<b>Prototype</b>	<pre>Int32 FileDmRead (FileHand stream, void *startOfDmChunkP, Int32 destOffset, Int32 objSize, Int32 numObj, Err *errP)</pre>												
<b>Parameters</b>	<table><tr><td>--&gt; stream</td><td>Handle to open stream.</td></tr><tr><td>--&gt; startOfDmChunkP</td><td>Pointer to beginning of chunk, record or resource residing in a database.</td></tr><tr><td>destOffset</td><td>Offset from startOfDmChunkP (base pointer) to the destination area (must be &gt;= 0).</td></tr><tr><td>objSize</td><td>Size of each stream object to read.</td></tr><tr><td>numObj</td><td>Number of stream objects to read.</td></tr><tr><td>&lt;--&gt; errP</td><td>Pointer to variable that is to hold the error code returned by this function. Pass NULL to ignore. See the section "<a href="#">File Streaming Error Codes</a>" for more information.</td></tr></table>	--> stream	Handle to open stream.	--> startOfDmChunkP	Pointer to beginning of chunk, record or resource residing in a database.	destOffset	Offset from startOfDmChunkP (base pointer) to the destination area (must be >= 0).	objSize	Size of each stream object to read.	numObj	Number of stream objects to read.	<--> errP	Pointer to variable that is to hold the error code returned by this function. Pass NULL to ignore. See the section " <a href="#">File Streaming Error Codes</a> " for more information.
--> stream	Handle to open stream.												
--> startOfDmChunkP	Pointer to beginning of chunk, record or resource residing in a database.												
destOffset	Offset from startOfDmChunkP (base pointer) to the destination area (must be >= 0).												
objSize	Size of each stream object to read.												
numObj	Number of stream objects to read.												
<--> errP	Pointer to variable that is to hold the error code returned by this function. Pass NULL to ignore. See the section " <a href="#">File Streaming Error Codes</a> " for more information.												
<b>Result</b>	The number of whole objects that were read—note that the number of objects actually read may be less than the number requested.												
<b>Comments</b>	When the number of objects actually read is less than the number requested, you may be able to determine the cause of this result by examining the return value of the errP parameter or by calling the <a href="#">FileGetLastError</a> function. If the cause is insufficient data in the stream to satisfy the full request, the current stream position is at end-of-file and the "end of file" indicator is set. If a non-NULL pointer was passed as the value of the errP parameter when the FileDmRead function was called and an error was encountered, *errP holds a non-zero error code when the function returns. In												

## File Streaming

### File Streaming Functions

---

addition, the [FileError](#) and [FileEOF](#) functions may be used to check for I/O errors.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileRead](#), [FileError](#), [FileEOF](#)

## FileEOF

**Purpose** Get end-of-file status (err = fileErrEOF indicates end of file condition).

**Declared In** FileStream.h

**Prototype** Err FileEOF (FileHand stream)

**Parameters** --> stream          Handle to open stream.

**Result** 0 if *not* end of file; non-zero if end of file. See the section "[File Streaming Error Codes](#)" for more information.

**Comments** This function's behavior is similar to that of the `fEOF` function provided by the C programming language runtime library. Use [FileClearerr](#) to clear the I/O error status.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileClearerr](#), [FileGetLastError](#), [FileRewind](#)

## FileError

<b>Purpose</b>	Get I/O error status.
<b>Declared In</b>	FileStream.h
<b>Prototype</b>	Err FileError (FileHand stream)
<b>Parameters</b>	--> stream            Handle to open stream.
<b>Result</b>	0 if no error, and non-zero if an I/O error indicator has been set for this stream. See the section " <a href="#">File Streaming Error Codes</a> " for more information.
<b>Comments</b>	This function's behavior is similar to that of the C programming language's <code>ferror</code> runtime function. Use <a href="#">FileClearerr</a> to clear the I/O error status.
<b>Compatibility</b>	Implemented only if <a href="#">3.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">FileClearerr</a> , <a href="#">FileGetLastError</a> , <a href="#">FileRewind</a>

## FileFlush

<b>Purpose</b>	Flush cached data to storage.
<b>Declared In</b>	FileStream.h
<b>Prototype</b>	Err FileFlush (FileHand stream)
<b>Parameters</b>	--> stream            Handle to open stream.
<b>Result</b>	0 if no error, or a <code>fileErr</code> code if an error occurs. See the section " <a href="#">File Streaming Error Codes</a> " for more information.
<b>Comments</b>	It is not always necessary to call this function explicitly—certain operations flush the contents of a stream automatically; for example,

## File Streaming

### File Streaming Functions

---

streams are flushed when they are closed. Because this function's behavior is similar to that of the `fflush` function provided by the C programming language runtime library, you only need to call it explicitly under circumstances similar to those in which you would call `fflush` explicitly.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## FileGetLastError

**Purpose** Get error code from last operation on file stream, and clear the last error code value (will not change end of file or I/O error status -- use [FileClearerr](#) to reset all error codes)

**Declared In** `FileStream.h`

**Prototype** `Err FileGetLastError (FileHand stream)`

**Parameters** `--> stream` Handle to open stream.

**Result** Error code returned by the last file stream operation. See the section "[File Streaming Error Codes](#)" for more information.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileClearerr](#), [FileEOF](#), [FileError](#)

## FileOpen

<b>Purpose</b>	Open existing file stream or create an open file stream for I/O in the mode specified by the <code>openMode</code> parameter.										
<b>Declared In</b>	<code>FileStream.h</code>										
<b>Prototype</b>	<pre>FileHand FileOpen (UInt16 cardNo, const Char *nameP, UInt32 type, UInt32 creator, UInt32 openMode, Err *errP)</pre>										
<b>Parameters</b>	<table><tr><td><code>cardNo</code></td><td>Card on which the file stream to open resides. Currently, no Palm Powered™ devices support multiple cards, so this value must be 0.</td></tr><tr><td><code>--&gt; nameP</code></td><td>Pointer to text string that is the name of the file stream to open or create. This value must be a valid name—no wildcards allowed, must not be NULL.</td></tr><tr><td><code>type</code></td><td>File type of stream to open or create. Pass 0 for wildcard, in which case <code>sysFileTFileStream</code> is used if the stream needs to be created and <code>fileModeTemporary</code> is not specified. If <code>type</code> is 0 and <code>fileModeTemporary</code> is specified, then <code>sysFileTTemp</code> is used for the file type of the stream this function creates.</td></tr><tr><td><code>creator</code></td><td>Creator of stream to open or create. Pass 0 for wildcard, in which case the current application's creator ID is used for the creator of the stream this function creates.</td></tr><tr><td><code>openMode</code></td><td>Mode in which to open the file stream. You must specify only one primary mode selector. Additionally, you can use the <code> </code> operator (bitwise inclusive OR) to append one or more secondary mode selectors to the primary mode selector. See <a href="#">“Primary Open Mode Constants”</a> and <a href="#">“Secondary Open Mode Constants”</a> for the list of possible values.</td></tr></table>	<code>cardNo</code>	Card on which the file stream to open resides. Currently, no Palm Powered™ devices support multiple cards, so this value must be 0.	<code>--&gt; nameP</code>	Pointer to text string that is the name of the file stream to open or create. This value must be a valid name—no wildcards allowed, must not be NULL.	<code>type</code>	File type of stream to open or create. Pass 0 for wildcard, in which case <code>sysFileTFileStream</code> is used if the stream needs to be created and <code>fileModeTemporary</code> is not specified. If <code>type</code> is 0 and <code>fileModeTemporary</code> is specified, then <code>sysFileTTemp</code> is used for the file type of the stream this function creates.	<code>creator</code>	Creator of stream to open or create. Pass 0 for wildcard, in which case the current application's creator ID is used for the creator of the stream this function creates.	<code>openMode</code>	Mode in which to open the file stream. You must specify only one primary mode selector. Additionally, you can use the <code> </code> operator (bitwise inclusive OR) to append one or more secondary mode selectors to the primary mode selector. See <a href="#">“Primary Open Mode Constants”</a> and <a href="#">“Secondary Open Mode Constants”</a> for the list of possible values.
<code>cardNo</code>	Card on which the file stream to open resides. Currently, no Palm Powered™ devices support multiple cards, so this value must be 0.										
<code>--&gt; nameP</code>	Pointer to text string that is the name of the file stream to open or create. This value must be a valid name—no wildcards allowed, must not be NULL.										
<code>type</code>	File type of stream to open or create. Pass 0 for wildcard, in which case <code>sysFileTFileStream</code> is used if the stream needs to be created and <code>fileModeTemporary</code> is not specified. If <code>type</code> is 0 and <code>fileModeTemporary</code> is specified, then <code>sysFileTTemp</code> is used for the file type of the stream this function creates.										
<code>creator</code>	Creator of stream to open or create. Pass 0 for wildcard, in which case the current application's creator ID is used for the creator of the stream this function creates.										
<code>openMode</code>	Mode in which to open the file stream. You must specify only one primary mode selector. Additionally, you can use the <code> </code> operator (bitwise inclusive OR) to append one or more secondary mode selectors to the primary mode selector. See <a href="#">“Primary Open Mode Constants”</a> and <a href="#">“Secondary Open Mode Constants”</a> for the list of possible values.										

## File Streaming

### File Streaming Functions

---

`<--> errP` Pointer to variable that is to hold the error code returned by this function. Pass `NULL` to ignore. See the section "[File Streaming Error Codes](#)" for a list of error codes.

**Result** If successful, returns a handle to an open file stream; otherwise, returns 0.

In some cases, on some platforms, [FileOpen](#) returns a non-zero value when it has failed to open a file; thus, it is always a good idea to check the `errP` parameter value to determine if an error has occurred.

**Comments** The `fileModeReadOnly`, `fileModeReadWrite`, `fileModeUpdate`, and `fileModeAppend` modes are mutually exclusive—pass only one of them to the `FileOpen` function!

When the `fileModeTemporary` open mode is used and the file type passed to `FileOpen` is 0, the `FileOpen` function uses `sysFileTTemp` (defined in `SystemMgr.rh`) for the file type, as recommended. In future versions of Palm OS, this configuration will enable the automatic cleanup of undeleted temporary files after a system crash. Automatic post-crash cleanup is not implemented in current versions of Palm OS.

To open a file stream even if it has a different type and creator than specified, pass the `fileModeAnyTypeCreator` selector as a flag in the `openMode` parameter to the [FileOpen](#) function.

The `fileModeLeaveOpen` mode is an esoteric option that most applications should not use. It may be useful for a library that needs to open a stream from the current application's context and keep it open even after the current application quits. By default, Palm OS automatically closes all databases that were opened in a particular application's context when that application quits. The `fileModeLeaveOpen` option overrides this default behavior.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## FileRead

<b>Purpose</b>	A macro that reads data from a stream into a buffer. Do not use this macro to read data into a chunk, record or resource residing in a database—you must use the <a href="#">FileDmRead</a> macro for such operations.	
<b>Declared In</b>	FileStream.h	
<b>Prototype</b>	<code>Int32 FileRead (FileHand stream, void *bufP, Int32 objSize, Int32 numObj, Err *errP)</code>	
<b>Parameters</b>	<code>--&gt; stream</code>	Handle to open stream.
	<code>--&gt; bufP</code>	Pointer to beginning of buffer into which data is read
	<code>objSize</code>	Size of each stream object to read.
	<code>numObj</code>	Number of stream objects to read.
	<code>&lt;--&gt; errP</code>	Pointer to variable that is to hold the error code returned by this function. Pass NULL to ignore. See the section " <a href="#">File Streaming Error Codes</a> " for a list of error codes.
<b>Result</b>	The number of whole objects that were read—note that the number of objects actually read may be less than the number requested.	
<b>Comments</b>	Do not use this macro to read data into a chunk, record or resource residing in a database—you must use the <a href="#">FileDmRead</a> macro for such operations.  When the number of objects actually read is fewer than the number requested, you may be able to determine the cause of this result by examining the return value of the <code>errP</code> parameter or by calling the <a href="#">FileGetLastError</a> function. If the cause is insufficient data in the stream to satisfy the full request, the current stream position is at end-of-file and the "end of file" indicator is set. If a non-NULL pointer was passed as the value of the <code>errP</code> parameter when the <code>FileRead</code> function was called and an error was encountered, <code>*errP</code> holds a non-zero error code when the function returns. In	

## File Streaming

### File Streaming Functions

---

addition, the [FileError](#) and [FileEOF](#) functions may be used to check for I/O errors.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileDmRead](#)

## FileRewind

**Purpose** Reset position marker to beginning of stream and clear all error codes.

**Declared In** FileStream.h

**Prototype** Err FileRewind (FileHand stream)

**Parameters** --> stream          Handle to open stream.

**Result** 0 if no error, or a fileErr code if an error occurs. See the section "[File Streaming Error Codes](#)" for more information.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileSeek](#), [FileTell](#), [FileClearerr](#), [FileEOF](#), [FileError](#), [FileGetLastError](#)

## FileSeek

**Purpose** Set current position within a file stream, extending the stream as necessary if it was opened with write access.

**Declared In** FileStream.h

**Prototype** Err FileSeek (FileHand stream, Int32 offset, FileOriginEnum origin)

**Parameters** --> stream          Handle to open stream.

offset	Position to set, expressed as the number of bytes from origin. This value may be positive, negative, or 0.
origin	Describes the origin of the position change. Possible values are:  fileOriginBeginning From the beginning (first data byte of file).  fileOriginCurrent From the current position.  fileOriginEnd From the end of file (one position beyond last data byte).

**Result** 0 if no error, or a `fileErr` code if an error occurs. See the section [“File Streaming Error Codes”](#) for more information.

**Comments** Attempting to seek beyond end-of-file in a read-only stream results in an I/O error.

This function’s behavior is similar to that of the `fseek` function provided by the C programming language runtime library.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileRewind](#), [FileTell](#)

## FileTell

**Purpose** Retrieves the current position and, optionally, file size, of a stream.

**Declared In** `FileStream.h`

**Prototype** `Int32 FileTell (FileHand stream, Int32 *fileSizeP, Err *errP)`

**Parameters** `--> stream` Handle to open stream.

## File Streaming

### File Streaming Functions

---

<code>&lt;-&gt; fileSizeP</code>	Pointer to variable that holds value describing size of stream in bytes when this function returns. Pass NULL to ignore.
<code>&lt;--&gt; errP</code>	Pointer to variable that is to hold the error code returned by this function. Pass NULL to ignore. See the section " <a href="#">File Streaming Error Codes</a> " for a list of possible error codes.

**Result** If successful, returns current position, expressed as an offset in bytes from the beginning of the stream. If an error was encountered, returns -1 as a signed long integer.

**Comments** The `FileTell` function can return the size of the input stream; as such, it provides some of the functionality of the standard C library `stat` function. Note, however, that unlike the `stat` function, `FileTell` requires that the file be open.

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

**See Also** [FileRewind](#), [FileSeek](#)

## FileTruncate

**Purpose** Truncate the file stream to a specified size; not allowed on streams open in destructive read mode or read-only mode.

**Declared In** `FileStream.h`

**Prototype** `Err FileTruncate (FileHand stream, Int32 newSize)`

**Parameters**

<code>--&gt; stream</code>	Handle of open stream.
<code>newSize</code>	New size; must not exceed current stream size.

**Result** 0 if no error, or a `fileErr` code if an error occurs. See the section "[File Streaming Error Codes](#)" for a list of possible error codes.

**Compatibility**    Implemented only if [3.0 New Feature Set](#) is present.

**See Also**        [FileTell](#)

## FileWrite

**Purpose**            Write data to a stream.

**Declared In**      FileStream.h

**Prototype**        `Int32 FileWrite (FileHand stream,  
const void *dataP, Int32 objSize, Int32 numObj,  
Err *errP)`

**Parameters**

--> stream	Handle to open stream.
--> dataP	Pointer to buffer holding data to write.
objSize	Size of each stream object to write; must be $\geq 0$ .
numObj	Number of stream objects to write.
<--> errP	Optional pointer to variable that holds the error code returned by this function. Pass NULL to ignore. See the section " <a href="#">File Streaming Error Codes</a> " for a list of possible error codes.

**Result**            The number of whole objects that were written—note that the number of objects actually written may be less than the number requested. Should available storage be insufficient to satisfy the entire request, as much of the requested data as possible is written to the stream, which may result in the last object in the stream being incomplete.

**Comments**        Writing to files opened without write access or those that are in destructive read state is not allowed; thus, you cannot call the [FileWrite](#), [FileSeek](#), or [FileTruncate](#) functions on a stream that is in destructive read mode. One exception to this rule applies to streams that were opened in "write + append" mode and then switched into destructive read state. In this case, the `FileWrite` function can append data to the stream, but it also preserves the

## **File Streaming**

### *File Streaming Functions*

---

current stream position so that subsequent reads pick up where they left off (you can think of this as a pseudo-pipe).

**Compatibility** Implemented only if [3.0 New Feature Set](#) is present.

## File Streaming Error Codes

This section lists all error codes returned by the file streaming functions.

<b>Error Code</b>	<b>Value</b>	<b>Meaning</b>
<code>fileErrMemErr</code>	<code>(fileErrorClass   1)</code>	Out of memory error
<code>fileErrInvalidParam</code>	<code>(fileErrorClass   2)</code>	Invalid parameter value passed
<code>fileErrCorruptFile</code>	<code>(fileErrorClass   3)</code>	Alleged stream is corrupted, invalid, or not a stream
<code>fileErrNotFound</code>	<code>(fileErrorClass   4)</code>	Couldn't find the stream
<code>fileErrTypeCreatorMismatch</code>	<code>(fileErrorClass   5)</code>	Type and/or creator not what was specified
<code>fileErrReplaceError</code>	<code>(fileErrorClass   6)</code>	Couldn't replace existing stream
<code>fileErrCreateError</code>	<code>(fileErrorClass   7)</code>	Couldn't create new stream
<code>fileErrOpenError</code>	<code>(fileErrorClass   8)</code>	Generic open error
<code>fileErrInUse</code>	<code>(fileErrorClass   9)</code>	Stream couldn't be opened or deleted because it is in use
<code>fileErrReadOnly</code>	<code>(fileErrorClass   10)</code>	Couldn't open in write mode because existing stream is read-only
<code>fileErrInvalidDescriptor</code>	<code>(fileErrorClass   11)</code>	Invalid file descriptor (FileHandle)

## File Streaming

### *File Streaming Error Codes*

---

<b>Error Code</b>	<b>Value</b>	<b>Meaning</b>
<code>fileErrCloseError</code>	<code>(fileErrorClass   12)</code>	Error closing the stream
<code>fileErrOutOfBounds</code>	<code>(fileErrorClass   13)</code>	Attempted operation went out of bounds of the stream
<code>fileErrPermissionDenied</code>	<code>(fileErrorClass   14)</code>	Couldn't write to a stream open for read-only access
<code>fileErrIOError</code>	<code>(fileErrorClass   15)</code>	Generic I/O error
<code>fileErrEOF</code>	<code>(fileErrorClass   16)</code>	End-of-File error
<code>fileErrNotStream</code>	<code>(fileErrorClass   17)</code>	Attempted to open an entity that is not a stream

---

# Float Manager

---

This chapter provides reference material for the Float Manager API as follows:

- [Float Manager Data Structures](#)
- [Float Manager Functions](#)

The Float Manager API is declared in the header file `FloatMgr.h`. For more information on the Float Manager, see the section “[Floating-Point](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Float Manager Data Structures

### FlpCompDouble

Float Manager functions accept and require values of type `FlpDouble`. The `FlpCompDouble` union allows you to declare values that can be interpreted either as a double or as an `FlpDouble`. As well, this union contains fields that provide easy access to the component parts of the double-precision floating-point number.

```
typedef union {
    double d;
    FlpDouble fd;
    UInt32 ul[2];
    FlpDoubleBits fdb;
} FlpCompDouble
```

## Float Manager

### Float Manager Data Structures

---

#### Field Descriptions

d	Provides access to the value as a double.
fd	Provides access to the value as a <code>FlpDouble</code> , which can be passed to or received from many Float Manager functions.
ul	Provides access to the value as two long integers.
fdb	Provides access to specific fields.

#### FlpDoubleBits

This structure provides direct access to the component parts of an IEEE-754 double-precision floating-point number. Use the [FlpCompDouble](#) union to convert numbers of type `double` to and from `FlpDoubleBits`.

```
typedef struct {
    UInt32 sign : 1;
    Int32 exp : 11;
    UInt32 manH : 20;
    UInt32 manL;
} FlpDoubleBits
```

#### Field Descriptions

sign	The sign bit. You can also use the <a href="#">FlpGetSign</a> macro to obtain the sign bit, and the <a href="#">FlpNegate</a> , <a href="#">FlpSetNegative</a> , and <a href="#">FlpSetPositive</a> macros to set the sign bit.
exp	The bits that make up the exponent. You can also use the <a href="#">FlpGetExponent</a> macro to obtain the exponent value.
manH	The most-significant 20 bits of the mantissa.
manL	The least-significant 32 bits of the mantissa.

## Float Manager Functions

### FlpAToF

**Purpose** Convert a null-terminated ASCII string to a 64-bit floating-point number. The string must have the format:

[+|-] [digits] [.] [digits] [e|E[+|-] [digits]]

**Declared In** `FloatMgr.h`

**Prototype** `FlpDouble FlpAToF (const Char *s)`

**Parameters** `-> s` Pointer to the string to be converted.

**Result** Returns the value of the string as a floating-point number.

**Comment** The mantissa of the number is limited to 32 bits.

This function is close to being compatible with the ISO C library function `atof`. `atof` requires the form:

[+|-] digits [.] [digits] [(e|E) [+|-] digits]

In order to maintain backward compatibility with the Float Manager in Palm OS 1.0 (which could be used up to, but not including, Palm OS 4.0), this function considers **all** of the “digits” sections to be optional. Here’s a table showing the ISO and Palm OS behavior with some sample strings:

String	ISO	>= Palm OS 4.0	< Palm OS 4.0 <sup>1</sup>	Notes
“+”	+0	+0	+0	
“.3”	0.3	0.3	0.3	
“0.3e123”	0.3e123	0.3e123	0.3e12	The old Float Manager only allowed a 1 or 2 digit exponent.

## Float Manager

### Float Manager Functions

---

String	ISO	>= Palm OS 4.0	< Palm OS 4.0 <sup>1</sup>	Notes
"+1"	1	1	+0	The old Float Manager doesn't allow a leading '+' sign.
"1e+2"	1e2	1e2	1	The old Float Manager doesn't allow a '+' sign in the exponent.
"0.3E3"	0.3e3	0.3e3	0.3	The old Float Manager doesn't allow a capital 'E' to mark the exponent.
"4294967297"	4294967297	4294967297	1	The old Float Manager uses an unsigned long and wraps around.

---

1. Using the old Float Manager documented in [Appendix C, "1.0 Float Manager."](#) on page 2355.

Unlike `atof`, `FlpAToF` doesn't accept leading white-space characters and it doesn't accept decimal point characters other than `'.'`.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present. GCC users must use [FlpBufferAToF](#) instead of this function.

**See Also** [FlpFToA](#)

## FlpBase10Info

**Purpose** Extract detailed information on the base 10 form of a floating-point number: the base 10 mantissa, exponent, and sign.

**Declared In** `FloatMgr.h`

**Prototype** `Err FlpBase10Info (FlpDouble a, UInt32 *mantissaP, Int16 *exponentP, Int16 *signP)`

**Parameters** `-> a` The floating-point number.

<- mantissaP     The base 10 mantissa.  
<- exponentP     The base 10 exponent.  
<- signP         The sign: 1 if the number is negative, 0  
                  otherwise.

**Result**         Returns 0 if no error, or `flpErrOutOfRange` if the supplied floating-point number is either not a number (NaN) or is infinite.

**Comments**       The mantissa is normalized so it contains at least 8 significant digits when printed as an integer value.

**Compatibility**   Implemented only if [2.0 New Feature Set](#) is present.

**See Also**       [FlpGetExponent](#), [FlpGetSign](#)

## FlpBufferAToF

**Purpose**         Convert a null-terminated ASCII string to a floating-point number. The string must be in the format: `[-]x[.]yyyyyyyy[e[-]zz]`

**Declared In**    `FloatMgr.h`

**Prototype**     `void FlpBufferAToF (FlpDouble *result,  
                  const Char *s)`

**Parameters**    <- `result`         Pointer to the structure into which the return value is placed.  
                  -> `s`             Pointer to the null-terminated ASCII string to be converted.

**Result**         Returns the value of the string as a floating-point number.

**Comments**       See [FlpAToF](#) for a complete description of this function.

**Compatibility**   Implemented only if [2.0 New Feature Set](#) is present. Because the Palm OS ABI was not well-specified in this area, GCC by default implemented structure return differently from the compiler used to

## Float Manager

### Float Manager Functions

---

build the ROM. As a result, GCC users must use this function instead of [FlpAToF](#). CodeWarrior users can use either function; they are binary compatible.

## FlpBufferCorrectedAdd

<b>Purpose</b>	Adds two floating-point numbers and corrects for least-significant-bit errors when the result should be zero but is instead very close to zero.								
<b>Declared In</b>	FloatMgr.h								
<b>Prototype</b>	<pre>void FlpBufferCorrectedAdd (FlpDouble *result, FlpDouble firstOperand, FlpDouble secondOperand, Int16 howAccurate)</pre>								
<b>Parameters</b>	<table><tr><td><code>&lt;- result</code></td><td>Pointer to the structure into which the return value is placed.</td></tr><tr><td><code>-&gt; firstOperand</code></td><td>The first of the two numbers to be added.</td></tr><tr><td><code>-&gt; secondOperand</code></td><td>The second of the two numbers to be added.</td></tr><tr><td><code>-&gt; howAccurate</code></td><td>The smallest difference in exponents that won't force the result to zero. The value returned from this function is forced to zero if the difference between exponents in the smaller of the two operands and the result exceeds this value. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a <code>howAccurate</code> value of 48).</td></tr></table>	<code>&lt;- result</code>	Pointer to the structure into which the return value is placed.	<code>-&gt; firstOperand</code>	The first of the two numbers to be added.	<code>-&gt; secondOperand</code>	The second of the two numbers to be added.	<code>-&gt; howAccurate</code>	The smallest difference in exponents that won't force the result to zero. The value returned from this function is forced to zero if the difference between exponents in the smaller of the two operands and the result exceeds this value. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a <code>howAccurate</code> value of 48).
<code>&lt;- result</code>	Pointer to the structure into which the return value is placed.								
<code>-&gt; firstOperand</code>	The first of the two numbers to be added.								
<code>-&gt; secondOperand</code>	The second of the two numbers to be added.								
<code>-&gt; howAccurate</code>	The smallest difference in exponents that won't force the result to zero. The value returned from this function is forced to zero if the difference between exponents in the smaller of the two operands and the result exceeds this value. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a <code>howAccurate</code> value of 48).								
<b>Result</b>	Returns the calculated result.								
<b>Comments</b>	See <a href="#">FlpCorrectedAdd</a> for a complete description of this function.								
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present. Because the Palm OS ABI was not well-specified in this area, GCC by default								

implemented structure return differently from the compiler used to build the ROM. As a result, GCC users must use this function instead of [FlpCorrectedAdd](#). CodeWarrior users can use either function; they are binary compatible.

## FlpBufferCorrectedSub

<b>Purpose</b>	Subtracts two floating-point numbers and corrects for least-significant-bit errors when the result should be zero but is instead very close to zero.								
<b>Declared In</b>	FloatMgr.h								
<b>Prototype</b>	<pre>void FlpBufferCorrectedSub (FlpDouble *result, FlpDouble firstOperand, FlpDouble secondOperand, Int16 howAccurate)</pre>								
<b>Parameters</b>	<table><tr><td><code>&lt;- result</code></td><td>Pointer to the structure into which the return value is placed.</td></tr><tr><td><code>-&gt; firstOperand</code></td><td>The value from which <code>secondOperand</code> is to be subtracted.</td></tr><tr><td><code>-&gt; secondOperand</code></td><td>The value to subtract from <code>firstOperand</code>.</td></tr><tr><td><code>-&gt; howAccurate</code></td><td>The smallest difference in exponents that won't force the result to zero. The value returned from this function is forced to zero if the difference between exponents in the smaller of the two operands and the result exceeds this value. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a <code>howAccurate</code> value of 48).</td></tr></table>	<code>&lt;- result</code>	Pointer to the structure into which the return value is placed.	<code>-&gt; firstOperand</code>	The value from which <code>secondOperand</code> is to be subtracted.	<code>-&gt; secondOperand</code>	The value to subtract from <code>firstOperand</code> .	<code>-&gt; howAccurate</code>	The smallest difference in exponents that won't force the result to zero. The value returned from this function is forced to zero if the difference between exponents in the smaller of the two operands and the result exceeds this value. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a <code>howAccurate</code> value of 48).
<code>&lt;- result</code>	Pointer to the structure into which the return value is placed.								
<code>-&gt; firstOperand</code>	The value from which <code>secondOperand</code> is to be subtracted.								
<code>-&gt; secondOperand</code>	The value to subtract from <code>firstOperand</code> .								
<code>-&gt; howAccurate</code>	The smallest difference in exponents that won't force the result to zero. The value returned from this function is forced to zero if the difference between exponents in the smaller of the two operands and the result exceeds this value. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a <code>howAccurate</code> value of 48).								
<b>Result</b>	Returns the calculated result.								
<b>Comments</b>	See <a href="#">FlpCorrectedSub</a> for a complete description of this function.								

## Float Manager

### Float Manager Functions

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present. Because the Palm OS ABI was not well-specified in this area, GCC by default implemented structure return differently from the compiler used to build the ROM. As a result, GCC users must use this function instead of [FlpCorrectedSub](#). CodeWarrior users can use either function; they are binary compatible.

## FlpCorrectedAdd

**Purpose** Adds two floating-point numbers and corrects for least-significant-bit errors when the result should be zero but is instead very close to zero.

**Declared In** `FloatMgr.h`

**Prototype** `FlpDouble FlpCorrectedAdd  
(FlpDouble firstOperand, FlpDouble secondOperand,  
Int16 howAccurate)`

**Parameters**

- > `firstOperand` The first of the two numbers to be added.
- > `secondOperand` The second of the two numbers to be added.
- > `howAccurate` The smallest difference in exponents that won't force the result to zero. The value returned from `FlpCorrectedAdd` is forced to zero if, when the exponent of the result of the addition is subtracted from the exponent of the smaller of the two operands, the difference exceeds the value specified for `howAccurate`. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a `howAccurate` value of 48).

**Result** Returns the calculated result.

**Comments** Adding or subtracting a large number and a small number produces a result similar in magnitude to the larger number. Adding or

subtracting two numbers that are similar in magnitude can, depending on their signs, produce a result with a very small exponent (that is, a negative exponent that is large in magnitude). If the difference between the result's exponent and that of the operands is close to the number of significant bits expressible by the mantissa, it is quite possible that the result should in fact be zero.

There also exist cases where it may be useful to retain accuracy in the low-order bits of the mantissa. For instance:  $99999999 + 0.00000001 - 99999999$ . However, unless the fractional part is an exact (negative) power of two, it is doubtful that what few bits of mantissa that are available will be enough to properly represent the fractional value. In this example, the 99999999 requires 26 bits, leaving 26 bits for the .00000001; this guarantees inaccuracy after the subtraction.

The problem arises from the difficulty in representing decimal fractions such as 0.1 in binary. After about three successive additions or subtractions, errors begin to appear in the least significant bits of the mantissa. If the value represented by the most significant bits of the mantissa is then subtracted away, the least significant bit error is normalized and becomes the actual result—when in fact the result should be zero.

This problem is only an issue for addition and subtraction.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present. GCC users must use [FlpBufferCorrectedAdd](#) instead of this function.

**See Also** [FlpCorrectedSub](#)

### FlpCorrectedSub

- Purpose** Subtracts two floating-point numbers and corrects for least-significant-bit errors when the result should be zero but is instead very close to zero.
- Declared In** `FloatMgr.h`
- Prototype** `FlpDouble FlpCorrectedSub (FlpDouble firstOperand, FlpDouble secondOperand, Int16 howAccurate)`
- Parameters**
- > `firstOperand` The value from which `secondOperand` is to be subtracted.
  - > `secondOperand` The value to subtract from `firstOperand`.
  - > `howAccurate` The smallest difference in exponents that won't force the result to zero. The value returned from `FlpCorrectedSub` is forced to zero if, when the exponent of the result of the subtraction is subtracted from the exponent of the smaller of the two operands, the difference exceeds the value specified for `howAccurate`. Supply a value of zero for this parameter to obtain the default level of accuracy (which is equivalent to a `howAccurate` value of 48).
- Result** Returns the calculated result.
- Comments** See the comments for [FlpCorrectedAdd](#).
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present. GCC users must use [FlpBufferCorrectedSub](#) instead of this function.

## FlpFToA

- Purpose** Convert a floating-point number to a null-terminated ASCII string in exponential format: `[-]x.yyyyyyye[-]zz`
- Declared In** `FloatMgr.h`
- Prototype** `Err FlpFToA (FlpDouble a, Char *s)`
- Parameters**
- > `a` Floating-point number.
  - <-`s` Pointer to buffer to contain the ASCII string.
- Result** Returns 0 if no error, or `flpErrOutOfRange` if the supplied value is infinite or is not a number. In this case, the buffer is set to the string "INF", "-INF", or "NaN" as appropriate.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.
- See Also** [FlpAToF](#)

## FlpGetExponent

- Purpose** Macro that returns the exponent of a 64-bit floating-point value. The returned value has the bias applied, so it ranges from -1023 to +1024.
- Declared In** `FloatMgr.h`
- Prototype** `FlpGetExponent (x)`
- Parameters**
- > `x` The value from which the exponent is to be extracted.
- Result** Returns a `UInt32` containing the exponent of the specified value.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.
- See Also** [FlpBase10Info](#), [FlpGetSign](#)

## Float Manager

### Float Manager Functions

---

#### FlpGetSign

- Purpose** Macro that returns the sign of a 64-bit floating-point value.
- Declared In** `FloatMgr.h`
- Prototype** `FlpGetSign (x)`
- Parameters** `-> x` The value from which the sign bit is to be extracted.
- Result** Returns a `UInt32` with a nonzero value if the specified value is negative, and with a zero value if it is positive.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.
- See Also** [FlpBase10Info](#), [FlpGetExponent](#), [FlpNegate](#), [FlpSetNegative](#), [FlpSetPositive](#)

#### FlpIsZero

- Purpose** Macro that returns whether the specified 64-bit floating-point value is zero.
- Declared In** `FloatMgr.h`
- Prototype** `FlpIsZero (x)`
- Parameters** `-> x` The value for which the sign bit is desired.
- Result** Returns a `UInt32` with a nonzero value if the specified value is zero, and with a zero value if the specified value is other than zero.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## FlpNegate

<b>Purpose</b>	Macro that changes the sign bit of a 64-bit floating-point number.
<b>Declared In</b>	FloatMgr.h
<b>Prototype</b>	FlpNegate (x)
<b>Parameters</b>	-> x                      The value in which the sign bit is to be changed.
<b>Result</b>	Returns a 64-bit floating-point value which is the negative of the value specified by x.
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">FlpGetSign</a> , <a href="#">FlpSetNegative</a> , <a href="#">FlpSetPositive</a>

## FlpSetNegative

<b>Purpose</b>	Macro that ensures that a 64-bit floating-point number is negative.
<b>Declared In</b>	FloatMgr.h
<b>Prototype</b>	FlpSetNegative (x)
<b>Parameters</b>	-> x                      The value that is to be forced negative.
<b>Result</b>	If the supplied 64-bit floating-point value is negative, that value is returned unchanged. If the supplied value is positive, the negative of that value is returned.
<b>Compatibility</b>	Implemented only if <a href="#">2.0 New Feature Set</a> is present.
<b>See Also</b>	<a href="#">FlpGetSign</a> , <a href="#">FlpNegate</a> , <a href="#">FlpSetPositive</a>

## Float Manager

### Float Manager Functions

---

## FlpSetPositive

- Purpose** Macro that ensures that a 64-bit floating-point number is positive.
- Declared In** `FloatMgr.h`
- Prototype** `FlpSetPositive (x)`
- Parameters** `-> x` The value that is to be forced positive.
- Result** If the supplied 64-bit floating-point value is positive, that value is returned unchanged. If the supplied value is negative, its absolute value is returned.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.
- See Also** [FlpGetSign](#), [FlpNegate](#), [FlpSetNegative](#)

## FlpVersion

- Purpose** Returns the version number of the Float Manager.
- Declared In** `FloatMgr.h`
- Prototype** `UInt32 FlpVersion (void)`
- Parameters** None.
- Result** Returns the version number of the Float Manager. The current version is represented by the constant `flpVersion`, which is defined in `FloatMgr.h`.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

# Fonts

---

This chapter provides the following information regarding font support:

- [Font Data Structures](#)
- [Font Constants](#)
- [Font Resources](#)
- [Font Functions](#)

The header files `Font.h` and `FontSelect.h` declare the API that this chapter describes. For more information on fonts, see [Chapter 8, “Text,”](#) on page 251 of the *Palm OS Programmer’s Companion*, vol. I.

## Font Data Structures

### FontCharInfoPtr

The `FontCharInfoPtr` type points to a [FontCharInfoType](#) structure.

```
typedef FontCharInfoType *FontCharInfoPtr;
```

### FontCharInfoType

The `FontCharInfoType` structure defines an entry in the offset/width table for a font.

---

**WARNING!** Palm, Inc. does not support or provide backward compatibility for the `FontCharInfoType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

## Fonts

### Font Data Structures

---

```
typedef struct FontCharInfoTag {
    Int8 offset;
    Int8 width;
} FontCharInfoType;
```

#### Field Descriptions

`offset` This value is not currently used and must be set to 0.

`width` The exact width in pixels of the glyph. You can retrieve this information using the function [FntWCharWidth](#) or [FntCharWidth](#).

**New**

---

### FontDensityType

The `FontDensityType` structure defines an entry in the `densities` array in the [FontTypeV2](#) structure. The `densities` array specifies the location of each set of glyphs within an extended font resource.

---

**WARNING!** Palm, Inc. does not support or provide backward compatibility for the `FontDensityType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct FontDensityTag {
    Int16 density;
    UInt32 glyphBitsOffset;
} FontDensityType;
```

#### Field Description

<code>density</code>	Either <code>kDensityLow</code> or <code>kDensityDouble</code> .
<code>glyphBitsOffset</code>	Offset in bytes from the beginning of the font data to the start of the font image for this density.

### Compatibility

This structure is only defined if the [High-Density Display Feature Set](#) is present.

### FontID

The `FontID` enum specifies the IDs of available fonts. A font can either be a system-defined font or an application-defined font. You can obtain the ID of the current font using [FntGetFont](#) and change the font using [FntSetFont](#).

```
enum fontID {
    stdFont = 0x00,
    boldFont,
    largeFont,
    symbolFont,
    symbol11Font,
    symbol7Font,
    ledFont,
    largeBoldFont,
    fntAppCustomBase = 0x80
};
typedef enum fontID FontID;
```

### Value Descriptions

<code>stdFont</code>	A small standard font used to display user input. This font is small to display as much text as possible.
<code>boldFont</code>	Same size as <code>stdFont</code> but bold for easier reading. Used for text labels in the user interface.
<code>largeFont</code>	A larger font provided as an alternative for users who find the standard font too small to read.
<code>symbolFont</code>	Contains many special characters such as arrows, Graffiti® Shift Indicators, and so on.

## Fonts

### Font Data Structures

---

<code>symbol11Font</code>	Contains the check boxes, the large left arrow, and the large right arrow.
<code>symbol7Font</code>	Contains the up and down arrows used for the repeating button scroll arrows and the dimmed version of the same arrows.
<code>ledFont</code>	Contains the numbers 0 through 9, -, ., and the comma (.). Used by the Calculator application for its numeric display.
<code>largeBoldFont</code>	In Palm OS® 3.0 and later only. Same size as <code>largeFont</code> but bold.
<code>fontAppCustomBase</code>	The first available ID for application-defined fonts.

## FontPtr

The `FontPtr` type defines a pointer to a [FontType](#) structure.

```
typedef FontType *FontPtr;
```

## FontType

The `FontType` structure defines a font resource's header. The fields in this structure give general information about the font. Following the structure are several tables that Palm OS uses to draw the font on the screen. See "[Font Resource](#)" on page 718 for more information about the font resource.

---

**WARNING!** Palm, Inc. does not support or provide backward compatibility for the `FontType` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct FontTag {
    Int16 fontType;
    Int16 firstChar;
    Int16 lastChar;
    Int16 maxWidth;
```

```

        Int16 kernMax;
        Int16 nDescent;
        Int16 fRectWidth;
        Int16 fRectHeight;
        Int16 owTLoc;
        Int16 ascent;
        Int16 descent;
        Int16 leading;
        Int16 rowWords;
    } FontType;

```

**Field Descriptions**

fontType	A mask providing the general characteristics of the font. When creating an application-defined font resource, use 0x9000.
firstChar	Character code of first glyph in the font.
lastChar	Character code of last glyph in the font.
maxWidth	The maximum width in pixels of any glyph. In Palm OS, there is currently no difference between this field and fRectWidth.
kernMax	This value is not currently used and must be set to 0.
nDescent	This value is not currently used and must be set to 0.
fRectWidth	A metric of the font image. In Palm OS, this metric is equivalent to the maximum width in pixels of any glyph in the font. Use <a href="#">FntAverageCharWidth</a> to obtain this value.
fRectHeight	The height, including ascenders and descenders, of the glyphs in this font. Use <a href="#">FntCharHeight</a> to obtain this value.

## Fonts

### Font Data Structures

---

owTLoc	The offset in 16-bit words from this field to the first byte of the offset/width table. The offset/width table is a table of <a href="#">FontCharInfoType</a> structures giving the width of each character in the font. Do not access the offset/width table directly. Use <a href="#">FntWCharWidth</a> or <a href="#">FntCharWidth</a> instead.
ascent	The distance in pixels from the top of the font rectangle to its baseline. Use <a href="#">FntBaseLine</a> to obtain this value.
descent	The distance in pixels from the baseline to the bottom of the font rectangle. Use <a href="#">FntDescenderHeight</a> to obtain this value.
leading	The font's leading, which is the vertical space between lines of text, in pixels. This field is unused in Palm OS and must be set to 0. If your font requires a leading value, add blank space to the bottom of each of your glyphs. The <a href="#">FntLineHeight</a> function returns the size of the font's character cell plus the leading.
rowWords	The number of 16-bit words stored for each row of a glyph's bitmap where <code>fRectHeight</code> is the number of rows.

**New**

---

## FontTypeV2

The `FontTypeV2` structure defines the header for an extended font resource, which contains a separate set of glyphs for each screen density. Currently the only supported densities are `kDensityLow` and `kDensityDouble`. See "[Extended Font Resource](#)" on page 721 for more information.

---

**WARNING!** Palm, Inc. does not support or provide backward compatibility for the `FontCharTypeV2` structure. Never access its structure members directly, or your code may break in future versions. Use the information below for debugging purposes only.

---

```
typedef struct FontTagV2 {
    Int16  fontType;
    Int16  firstChar;
    Int16  lastChar;
    Int16  maxWidth;
    Int16  kernMax;
    Int16  nDescent;
    Int16  fRectWidth;
    Int16  fRectHeight;
    Int16  owTLoc;
    Int16  ascent;
    Int16  descent;
    Int16  leading;
    Int16  rowWords;
    Int16  version;
    Int16  densityCount;
    FontDensityType densities[0];
} FontTypeV2;
```

---

**NOTE:** All pixel values given in the fields below are in terms of the single-density font data.

---

### Field Descriptions

<code>fontType</code>	A mask providing the general characteristics of the font. When creating an application-defined extended font resource, use the value <code>fntExtendedFormatMask   0x9000</code> .
<code>firstChar</code>	Character code of first glyph in the font.
<code>lastChar</code>	Character code of last glyph in the font.

## Fonts

### Font Data Structures

---

maxWidth	The maximum width in pixels of any glyph. In Palm OS, there is currently no difference between this field and fRectWidth.
kernMax	This value is not currently used and must be set to 0.
nDescent	This value is not currently used and must be set to 0.
fRectWidth	A metric of the font image. In Palm OS, this metric is equivalent to the maximum width in pixels of any glyph in the font. Use <a href="#">FntAverageCharWidth</a> to obtain this value.
fRectHeight	The height, including ascenders and descenders, of the glyphs in this font. Use <a href="#">FntCharHeight</a> to obtain this value.
owTLoc	The offset in 16-bit words from this field to the first byte of the offset/width table. The offset/width table is a table of <a href="#">FontCharInfoType</a> structures giving the width of each character in the font. Do not access the offset/width table directly. Use <a href="#">FntWCharWidth</a> or <a href="#">FntCharWidth</a> instead.
ascent	The distance in pixels from the top of the font rectangle to its baseline. Use <a href="#">FntBaseLine</a> to obtain this value.
descent	The distance in pixels from the baseline to the bottom of the font rectangle. Use <a href="#">FntDescenderHeight</a> to obtain this value.
leading	The font's leading, which is the vertical space between lines of text, in pixels. This field is unused in Palm OS and must be set to 0. If your font requires a leading value, add blank space to the bottom of each of your glyphs. The <a href="#">FntLineHeight</a> function returns the size of the font's character cell plus the leading.

rowWords	The number of 16-bit words stored for each row of a glyph's bitmap where fRectHeight is the number of rows.
version	The version of the extended font resource. This value should be set to 1.
densityCount	The number of entries in the densities array.
densities	An array of one or more <a href="#">FontDensityType</a> structures identifying the glyphs for each supported density.

**Compatibility**

This structure is only defined if the [High-Density Display Feature Set](#) is present.

## Font Constants

Constant	Value	Description
checkboxFont	symbol11Font	A convenience constant that points to the font containing the checkbox bitmap.
fntMissingChar	-1	The value used for a character that does not have a definition in the current font. The missing character symbol is usually an open rectangle.
fntExtendedFormatMask	0x0200	A constant used for the fontType field of a font to indicate that it is an extended font resource.
fntTabChrWidth	20	The width of the tab character in pixels.

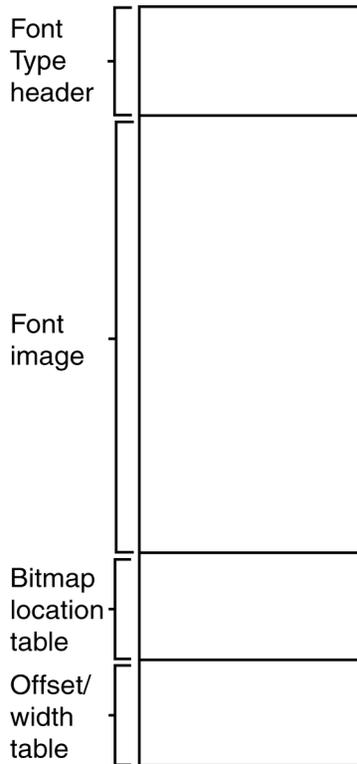

## Font Resources

### Font Resource

The font resource ( 'NFNT' ) represents a version 1 single-density font. This resource is the same as the Macintosh 'NFNT' resource with some restrictions. It contains a header followed by several tables that provide information about each glyph in the font.

[Figure 33.1](#) shows how the font resource is laid out in memory. [Table 33.1](#) describes each table within the font resource.

**Figure 33.1** Font resource ('NFNT')

**Table 33.1 Font resource description**

<b>Field</b>	<b>Description</b>
FontType header	Contains general information about the glyphs in the font. See <a href="#">FontType</a> .
Font image	<p>A raw bitmap image containing the packed character glyphs from left to right (see <a href="#">Figure 33.2</a> on page 720). This part of the resource tells Palm OS how to draw each character in the font. The height of the image is <code>fRectHeight</code> and the size is <code>rowWords * 2 * fRectHeight</code>.</p> <p>Place glyphs sequentially in order of increasing character code. Leave at least a one-pixel wide vertical column of space to the right of each image so that there is space between characters when Palm OS draws text on the screen. If your font requires leading, leave horizontal space at the bottom of the characters as well. The font image must end with the glyph for the missing character symbol.</p>
Bitmap location table	<p>A table of 16-bit words that specify the location of each glyph's entry in the font image. The location is specified as the bit offset from the start of the image to the glyph in the first row of the font image. The last entry in the table contains the offset of the column after the last bitmap. (See <a href="#">Figure 33.2</a> on page 720.)</p> <p>If you have skipped characters within an encoding, for each glyph that is missing, specify the same value for its location as the entry for the next glyph in the table.</p>

# Fonts

## Font Resources

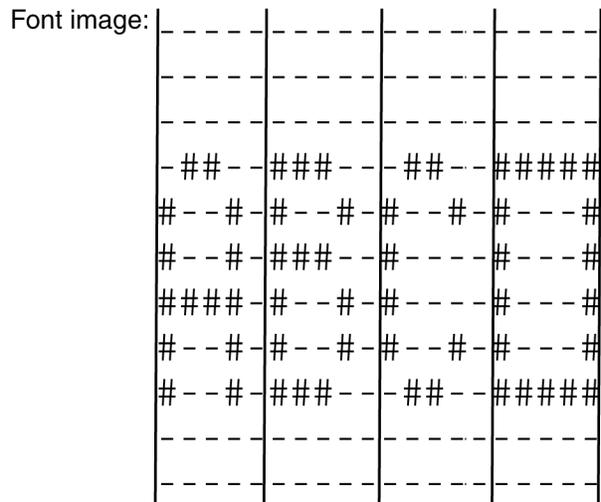

---

**Table 33.1 Font resource description (*continued*)**

Field	Description
Offset/width table	<p>A table that specifies how wide each glyph in the font is. On Macintosh systems, this table also specifies how each glyph kerns. Palm OS does not support kerning, as the offset value is ignored.</p> <p>Each entry in the offset/width table is two bytes long. The first byte should be 0, and the second byte should contain the glyph width, which must be greater than or equal to 0. If the glyph at this index does not have a bitmap in the font image, the values should be -1 and -1.</p>

[Figure 33.2](#) shows an example of the font image for a font that defines glyphs for four characters (A, B, C, and the missing character symbol) and the portion of the bitmap location table that provides the offsets for these characters. The last entry in the bitmap location table is the offset to the column after the last bitmap, or 0x0014.

**Figure 33.2 Font image and bitmap location table**

Bitmap location table values: 0x0000 0x0005 0x000A 0x000F 0x0014

---

## **Extended Font Resource**

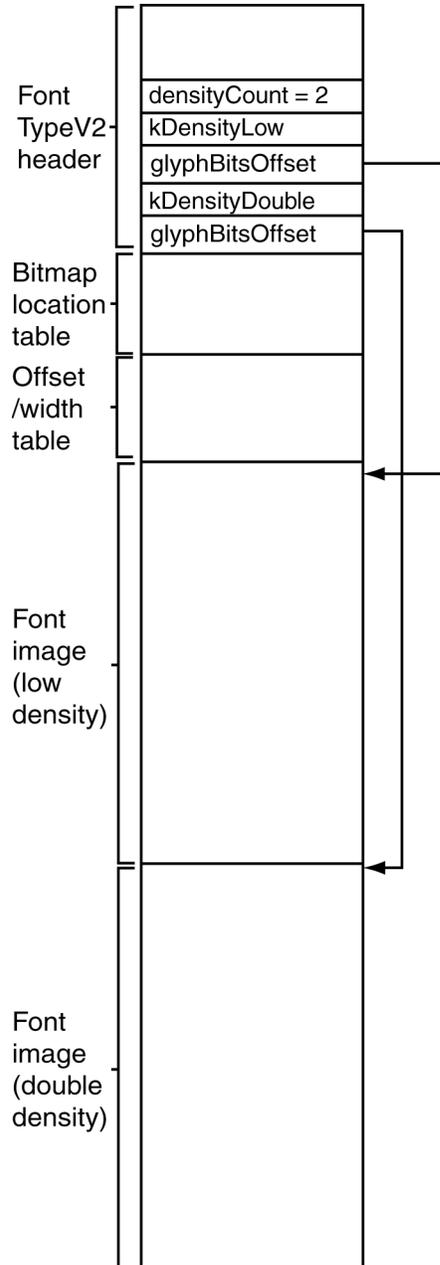

The extended font resource ( 'nfont' ) defines a font that supports multiple screen densities. Currently, only two screen densities are supported: the standard density of 80 dpi, as occurs on most devices that use a 160 X 160 pixel display, and double density of 160 dpi, as occurs on most devices that use a 320 X 320 pixel display. As shown in [Figure 33.3](#), the extended font resource is essentially:

- A [FontTypeV2](#) header giving all general information about the glyphs in the font. All metrics are in terms of the low-density version of the font.
- Tables for the low-density font. See “[Font Resource](#)” on page 718 for a description of these tables.
- The font image (set of glyphs) for each density specified by the font.

### **Compatibility**

This resource is only defined if the [High-Density Display Feature Set](#) is present.

**Figure 33.3 Extended font resource**

## Font Functions

### **FntAverageCharWidth**

- Purpose** Gets the *maximum* character width in pixels of the current font.
- Declared In** `Font.h`
- Prototype** `Int16 FntAverageCharWidth (void)`
- Parameters** None.
- Result** Returns the *maximum* character width (in pixels).
- Comments** This function returns the value of the `fRectHeight` field in the [FontType](#) structure for the current font. Because Palm OS does not support kerning, this value is the maximum width in pixels rather than the average width.

### **FntBaseLine**

- Purpose** Gets the distance from the top of the character cell to the baseline for the current font.
- Declared In** `Font.h`
- Prototype** `Int16 FntBaseLine (void)`
- Parameters** None.
- Result** Returns the ascent of the font (in pixels).

## Fonts

### Font Functions

---

#### FntCharHeight

- Purpose** Gets the character height of the current font including accents and descenders.
- Declared In** `Font.h`
- Prototype** `Int16 FntCharHeight (void)`
- Parameters** None.
- Result** Returns the height of the characters in the current font, expressed in pixels.

#### FntCharsInWidth

- Purpose** Finds the length in bytes of the characters from a specified string that fit within a passed width.
- Declared In** `Font.h`
- Prototype** `void FntCharsInWidth (Char const *string, Int16 *stringWidthP, Int16 *stringLengthP, Boolean *fitWithinWidth)`
- Parameters** `-> string` A pointer to the character string.  
`<-> stringWidthP` The maximum width to allow (in pixels). Upon return, contains the actual width allowed. Note that this value does not include any trailing spaces or tabs, which are stripped by this function.

`<-> stringLengthP`

The maximum length of text to allow, in bytes (assumes current font). Upon return, contains the number of bytes of text that can appear within the width. Note that this value does not include any trailing space or tabs, which are stripped by this function.

`<- fitWithinWidth`

Upon return, `false` if the string is considered truncated, `true` if it isn't.

**Result** Returns nothing.

**Comments** Spaces and tabs at the end of a string are ignored and removed. If the string fits within the specified width after spaces and tabs are removed, the `fitWithinWidth` value contains `true`. Characters after a carriage return are ignored, and the string is considered truncated.

This function is specifically designed for the code used to draw text fields. Consider using [FntWidthToOffset](#) in your application code instead, particularly if you do not want the special processing of trailing spaces, tabs, and carriage returns.

## FntCharsWidth

**Purpose** Gets the width of the specified character string. The **missing character symbol** (an open rectangle) is substituted for any character that does not exist in the current font.

**Declared In** `Font.h`

**Prototype** `Int16 FntCharsWidth (Char const *chars, Int16 len)`

**Parameters** `-> chars` Pointer to a string of characters.

## Fonts

### Font Functions

---

-> len                      Length in bytes of the string.

**Result**      Returns the width of the string, in pixels.

**Comments**      Like all functions that work with strings, this function returns correct results for strings with multi-byte characters as well as strings with only single-byte characters.

**See Also**      [FntCharWidth](#)

## FntCharWidth

**Purpose**      Gets the width of the specified character. If the specified character does not exist within the current font, the missing character symbol is substituted.

**Declared In**      Font.h

**Prototype**      Int16 FntCharWidth (Char ch)

**Parameters**      -> ch                      Character whose width is needed.

**Result**      Returns the width of the specified character (in pixels).

**Comments**      FntCharWidth works with single-byte characters only. To determine the pixel width of a single-byte character or a multi-byte character, use [FntWCharWidth](#) instead of this function in Palm OS 4.0 and higher. Alternatively, for compatibility with earlier versions of Palm OS, link with the PalmOSGlue library and call FntGlueWCharWidth. For more information, see [Chapter 75](#), “PalmOSGlue Library.”

**See Also**      [FntCharsWidth](#)

## FntDefineFont

<b>Purpose</b>	Makes a custom font available to your application.	
<b>Declared In</b>	Font.h	
<b>Prototype</b>	Err FntDefineFont (FontID font, FontPtr fontP)	
<b>Parameters</b>	-> font	A value greater than or equal to <code>fntAppFontCustomBase</code> that identifies the custom font to the system. Values less than that are reserved for system use. Note that font IDs are 8-bit unsigned values and so must be less than 256. See <a href="#">FontID</a> .
	-> fontP	Pointer to the custom font resource to be used by this function. This resource must remain locked until the calling application undefines the custom font or quits.
<b>Result</b>	<code>errNone</code>	No error
	<code>memErrNotEnoughSpace</code>	Insufficient dynamic heap space
<b>Comments</b>	<p>The custom font is available only when the application that called this function is running; when the application quits, the custom font is uninstalled automatically.</p> <p>The font this function specifies is not available at build time; as a result, some UI elements—labels, for example—cannot determine their bounds automatically as they do when using the built-in fonts.</p> <p>Before you use this function, you must load the font resource from the database and obtain a pointer to it. See “<a href="#">Creating Custom Fonts</a>” on page 275 of the <i>Palm OS Programmer’s Companion</i>, vol. I for more information.</p>	
<b>Compatibility</b>	Implemented only if <a href="#">3.0 New Feature Set</a> is present.	
	Palm OS 4.0 and later do not allow a NULL value for the <code>fontP</code> parameter; therefore, you cannot undefine a font using	

## Fonts

### Font Functions

---

`FntDefineFont (myFontID, NULL)`. Earlier versions of Palm OS allowed the `NULL` value. Note that there is usually no need to undefine a font.

Palm OS 3.0 and 3.1 have problems with font ID values greater than 131. These problems are fixed in later releases of Palm OS.

**See Also** [FontSelect](#), [FntSetFont](#)

## FntDescenderHeight

**Purpose** Gets the height of a character's descender in the current font. The height of a descender is the distance between the baseline and the bottom of the character cell.

**Declared In** `Font.h`

**Prototype** `Int16 FntDescenderHeight (void)`

**Parameters** None.

**Result** Returns the height of a descender, expressed in pixels.

## FntGetFont

**Purpose** Gets the font ID of the current font.

**Declared In** `Font.h`

**Prototype** `FontID FntGetFont (void)`

**Parameters** None.

**Result** Returns the ID of the current font.

**Comments** The current font is the font stored in the draw state. It is used when drawing characters directly onto the screen. Most user interface

elements, such as fields, tables, labels, and buttons, do not use the current font.

**See Also** [FntSetFont](#), [FntGetFontPtr](#), [FontID](#)

## **FntGetFontPtr**

**Purpose** Gets a pointer to the current font.

**Declared In** `Font.h`

**Prototype** `FontPtr FntGetFontPtr (void)`

**Parameters** None.

**Result** Returns a pointer to the current font.

**Comments** The current font is the font stored in the draw state. It is used when drawing characters directly onto the screen. Most user interface elements, such as fields, tables, labels, and buttons, do not use the current font.

**See Also** [FntGetFont](#)

## **FntGetScrollValues**

**Purpose** Gets the values needed to update a scroll bar based on a specified string and the position within the string.

**Declared In** `Font.h`

**Prototype** `void FntGetScrollValues (Char const *chars, UInt16 width, UInt16 scrollPos, UInt16 *linesP, UInt16 *topLine)`

**Parameters** `-> chars` A null-terminated string.

## Fonts

### Font Functions

---

-> width	The width of a line of text in the display, given in pixels.
-> scrollPos	The byte offset of the first character displayed on the topmost line.
<- linesP	Number of lines required to display the string.
<- topLine	The line of text that is the topmost visible line. Line numbering starts with 0.

**Result** Returns nothing. Stores the number of lines of text in `linesP` and the top visible line in `topLine`.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [FldGetScrollValues](#)

## FntIsAppDefined

**Purpose** Macro that returns `true` if the font is defined by the application or `false` if it is defined by the system.

**Declared In** `Font.h`

**Prototype** `FntIsAppDefined (fnt)`

**Parameters** -> `fnt` The [FontID](#) of a font.

**Result** Boolean that indicates if the font is an application-defined font. Returns `true` if application-defined, `false` if system-defined.

## FntLineHeight

- Purpose** Gets the height of a line in the current font. The height of a line is the height of the character cell plus the space between lines (the external leading).
- Declared In** `Font.h`
- Prototype** `Int16 FntLineHeight (void)`
- Parameters** None.
- Result** Returns the height in pixels of a line in the current font.

## FntLineWidth

- Purpose** Gets the width of the specified line of text, taking tab characters into account. The function assumes that the characters passed are left-aligned and that the first character in the string is the first character drawn on a line. In other words, this routine doesn't work for characters that don't start at the beginning of a line.
- Declared In** `Font.h`
- Prototype** `Int16 FntLineWidth (Char const *pChars, UInt16 length)`
- Parameters**
- |           |                                    |
|-----------|------------------------------------|
| -> pChars | Pointer to a string of characters. |
| -> length | Length in bytes of the string.     |
- Result** Returns the line width (in pixels).

## Fonts

### Font Functions

---

## FntSetFont

- Purpose** Sets the current font.
- Declared In** `Font.h`
- Prototype** `FontID FntSetFont (FontID font)`
- Parameters** `-> font` ID of the font to make the current font.
- Result** Returns the ID of the previous font.
- Comments** If the specified font ID is invalid, this function sets the current font to `stdFont`.
- The current font is the font stored in the draw state. It is used when drawing characters directly onto the screen. Most user interface elements, such as fields, tables, labels, and buttons, do not use the current font. To set the font for one of these elements, check the API for that element. If the element's API doesn't have a function to set the font programmatically, check the PalmOSGlue library.
- See Also** [FntGetFont](#)

## FntWCharWidth

- Purpose** Gets the width of the specified character. If the specified character does not exist within the current font, the missing character symbol is substituted.
- Declared In** `Font.h`
- Prototype** `Int16 FntWCharWidth (WChar iChar)`
- Parameters** `-> iChar` Character whose width is needed.
- Result** Returns the width of the specified character (in pixels).

**Comments** `FntWCharWidth` works with both single-byte characters and multi-byte characters. However, you should always pass a `WChar` variable to this function rather than a `Char` to avoid sign extension problems on values `0x80` and higher.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present. If you want to use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `FntGlueWCharWidth`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [FntCharWidth](#)

## **FntWidthToOffset**

**Purpose** Given a pixel position, gets the offset of the character displayed at that location.

**Declared In** `Font.h`

**Prototype** `Int16 FntWidthToOffset (Char const *pChars, UInt16 length, Int16 pixelWidth, Boolean *leadingEdge, Int16 *truncWidth)`

**Parameters**

-> <code>pChars</code>	Pointer to the character string.
-> <code>length</code>	The length in bytes of <code>pChars</code> .
-> <code>pixelWidth</code>	A horizontal pixel offset from the beginning of the string.
<- <code>leadingEdge</code>	Set to <code>true</code> if the pixel position <code>pixelWidth</code> falls on the left side of the character. Pass <code>NULL</code> for this parameter if you don't need this information.

## Fonts

### Font Functions

---

`<- truncWidth`      The width of the text (in pixels) up to but not including the returned offset. Pass `NULL` for this parameter if you don't need this information.

**Result**      Returns the byte offset into `pChars` of the character that contains the pixel offset `pixelWidth`. If `pixelWidth` is past the right edge of the string, the function returns the byte offset past the last character in `pChars`, and `truncWidth` contains the width required to display the entire string.

**Compatibility**      Implemented only if [3.1 New Feature Set](#) is present. If you want to use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `FntGlueWidthToOffset`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## FntWordWrap

**Purpose**      Given a string, determines how many bytes of text can be displayed within the specified width with a line break at a tab or space character.

**Declared In**      `Font.h`

**Prototype**      `UInt16 FntWordWrap (Char const *chars, UInt16 maxWidth)`

**Parameters**      `-> chars`              A pointer to a null-terminated string.  
`-> maxWidth`              The maximum line width in pixels.

**Result**      Returns the length of the line, in bytes. If the entire string cannot be displayed within `maxWidth`, the value that this function returns specifies the offset where the line should be broken, which is typically following a space, tab, or line-feed character.

**Compatibility**      Implemented only if [2.0 New Feature Set](#) is present.

**See Also**      [FldWordWrap](#)

## **FntWordWrapReverseNLines**

- Purpose** Word wraps a text string backwards by the number of lines specified. The character position of the start of the first line and the number of lines that are actually word wrapped are returned.
- Declared In** `Font.h`
- Prototype**  
`void FntWordWrapReverseNLines  
(Char const *const chars, UInt16 maxWidth,  
UInt16 *linesToScrollP, UInt16 *scrollPosP)`
- Parameters**
- `-> chars` A pointer to a null-terminated string.
  - `-> maxWidth` The maximum line width in pixels.
  - `<-> linesToScrollP` The number of lines to scroll. Upon return, contains the number of lines that were scrolled.
  - `<-> scrollPosP` The byte offset of the first character displayed on the topmost line. Upon return, contains the first character after wrapping.
- Result** Returns nothing. Stores the first character after wrapping and the number of lines scrolled in `scrollPosP` and `linesToScrollP`.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## Fonts

### Font Functions

---

## FontSelect

<b>Purpose</b>	Displays a dialog from which the user can choose one of the system-supplied fonts, and returns a <code>FontID</code> value representing the user's choice.	
<b>Declared In</b>	<code>FontSelect.h</code>	
<b>Prototype</b>	<code>FontID FontSelect (FontID fontID)</code>	
<b>Parameters</b>	<code>-&gt; fontID</code>	A <code>FontID</code> value specifying the font to be highlighted as the default choice in the dialog box that this function displays. This value must be one of the following system-supplied constants:  <code>stdFont</code> Standard plain text font.  <code>boldFont</code> Bold version of <code>stdFont</code> .  <code>largeFont</code> A large plain text font (Japanese devices only).  <code>largeBoldFont</code> Larger version of <code>boldFont</code> .
<b>Result</b>	Returns a <code>FontID</code> value representing the font that the user chose.	
<b>Comments</b>	When your application launches for the first time, it should determine the system's default font. The default font varies based on locale. You can use <a href="#">FntGlueGetDefaultFontID</a> from the PalmOSGlue library to determine the default font as follows:  <pre>fntID = FntGlueGetDefaultFontID (defaultSystemFont) ;</pre>	
<b>Compatibility</b>	Implemented only if <a href="#">3.0 New Feature Set</a> is present.	
<b>See Also</b>	<a href="#">FntGetFont</a> , <a href="#">FntSetFont</a>	

# Graffiti Manager

---

This chapter provides reference material for the Graffiti<sup>®</sup> manager. The Graffiti manager API is declared in the header file `Graffiti.h`.

For more information on the Graffiti manager, see “[The Graffiti Manager](#)” on page 60 of the *Palm OS Programmer’s Companion*, vol. I.

## Graffiti Manager Functions

### GrfAddMacro

<b>Purpose</b>	Add a macro to the macro list.						
<b>Declared In</b>	<code>Graffiti.h</code>						
<b>Prototype</b>	<code>Err GrfAddMacro (const Char *nameP, UInt8 *macroDataP, UInt16 dataLen)</code>						
<b>Parameters</b>	<table><tr><td><code>nameP</code></td><td>Name of macro.</td></tr><tr><td><code>macroDataP</code></td><td>Data of macro.</td></tr><tr><td><code>dataLen</code></td><td>Size of macro data in bytes.</td></tr></table>	<code>nameP</code>	Name of macro.	<code>macroDataP</code>	Data of macro.	<code>dataLen</code>	Size of macro data in bytes.
<code>nameP</code>	Name of macro.						
<code>macroDataP</code>	Data of macro.						
<code>dataLen</code>	Size of macro data in bytes.						
<b>Result</b>	Returns 0 if no error; returns <code>grfErrNoMacros</code> , <code>grfErrMacroPtrTooSmall</code> , <code>dmErrNotValidRecord</code> , <code>dmErrWriteOutOfBounds</code> if an error occurs.						
<b>See Also</b>	<a href="#">GrfGetMacro</a> , <a href="#">GrfGetMacroName</a> , <a href="#">GrfDeleteMacro</a>						

## Graffiti Manager

### *Graffiti Manager Functions*

---

#### **GrfAddPoint**

- Purpose** Add a point to the Graffiti point buffer.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfAddPoint (PointType *pt)`
- Parameters** `pt` Pointer to point buffer.
- Result** Returns 0 if no error; returns `grfErrPointBufferFull` if an error occurs.
- See Also** [GrfFlushPoints](#)

#### **GrfCleanState**

- Purpose** Remove any temporary shifts from the dictionary state.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfCleanState (void)`
- Parameters** None
- Result** Returns 0 if no error, or `grfErrNoDictionary` if an error occurs.
- See Also** [GrfInitState](#)

## **GrfDeleteMacro**

- Purpose** Delete a macro from the macro list.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfDeleteMacro (UInt16 index)`
- Parameters** `index` Index of the macro to delete.
- Result** Returns 0 if no error, or `grfErrNoMacros`, `grfErrMacroNotFound` if an error occurs.
- See Also** [GrfAddMacro](#)

## **GrfFilterPoints**

- Purpose** Filter the points in the Graffiti point buffer.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfFilterPoints (void)`
- Parameters** None.
- Result** Always returns 0.
- See Also** [GrfMatch](#)

## Graffiti Manager

### *Graffiti Manager Functions*

---

#### **GrfFindBranch**

- Purpose** Locate a branch in the Graffiti dictionary by flags.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfFindBranch (UInt16 flags)`
- Parameters** `flags` Flags of the branch you're searching for.
- Result** Returns 0 if no error, or `grfErrNoDictionary` or `grfErrBranchNotFound` if an error occurs.
- See Also** [GrfCleanState](#), [GrfInitState](#)

#### **GrfFlushPoints**

- Purpose** Dispose of all points in the Graffiti point buffer.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfFlushPoints (void)`
- Parameters** None.
- Result** Always returns 0.
- See Also** [GrfAddPoint](#)

## GrfGetAndExpandMacro

- Purpose** Look up and expand a macro in the current macros.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfGetAndExpandMacro (Char *nameP, UInt8 *macroDataP, UInt16 *dataLenP)`
- Parameters**
- |                         |   |
|-------------------------|---|
| <code>nameP</code>      | Name of macro to look up.   |
| <code>macroDataP</code> | Macro contents returned here.   |
| <code>dataLenP</code>   | On entry, size of <code>macroDataP</code> buffer; on exit, number of bytes in macro data. |
- Result** Returns 0 if no error, or `grfErrNoMacros` or `grfErrMacroNotFound` if an error occurs.
- See Also** [GrfAddMacro](#), [GrfGetMacro](#)

## GrfGetGlyphMapping

- Purpose** Look up a glyph in the dictionary and return the text.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfGetGlyphMapping (UInt16 glyphID, UInt16 *flagsP, void *dataPtrP, UInt16 *dataLenP, UInt16 *uncertainLenP)`
- Parameters**
- |                       |  |
|-----------------------|--|
| <code>glyphID</code>  | Glyph ID to look up.   |
| <code>flagsP</code>   | Returned dictionary flags.   |
| <code>dataPtrP</code> | Where returned text goes.  |
| <code>dataLenP</code> | On entry, size of <code>dataPtrP</code> ; on exit, number of bytes returned. |

## Graffiti Manager

### *Graffiti Manager Functions*

---

uncertainLenP    Return number of uncertain characters in text.

**Result**    Returns 0 if no error, or `grfErrNoDictionary` or `grfErrNoMapping` if an error occurs.

**See Also**    [GrfMatch](#)

## GrfGetMacro

**Purpose**    Look up a macro in the current macros.

**Declared In**    `Graffiti.h`

**Prototype**    `Err GrfGetMacro (Char *nameP, UInt8 *macroDataP, UInt16 *dataLenP)`

**Parameters**

<code>nameP</code>	Name of macro to lookup.
<code>macroDataP</code>	Macro contents returned here.
<code>dataLenP</code>	On entry: size of <code>macroDataP</code> buffer. On exit: number of bytes in macro data.

**Result**    Returns 0 if no error or `grfErrNoMacros`, `grfErrMacroNotFound`.

**See Also**    [GrfAddMacro](#)

## GrfGetMacroName

**Purpose**    Look up a macro name by index.

**Declared In**    `Graffiti.h`

**Prototype**    `Err GrfGetMacroName (UInt16 index, Char *nameP)`

**Parameters**

<code>index</code>	Index of macro.
--------------------	-----------------

nameP                      Name returned here.

**Result**                  Returns 0 if no error, or `grfErrNoMacros` or `grfErrMacroNotFound` if an error occurs.

**See Also**                [GrfAddMacro](#), [GrfGetMacro](#)

## **GrfGetNumPoints**

**Purpose**                  Return the number of points in the point buffer.

**Declared In**            `Graffiti.h`

**Prototype**             `Err GrfGetNumPoints (UInt16 *numPtsP)`

**Parameters**            `numPtsP`                Returned number of points.

**Result**                  Always returns 0.

**See Also**                [GrfAddPoint](#)

## **GrfGetPoint**

**Purpose**                  Return a point out of the Graffiti point buffer.

**Declared In**            `Graffiti.h`

**Prototype**             `Err GrfGetPoint (UInt16 index, PointType *pointP)`

**Parameters**            `index`                    Index of the point to get.  
`pointP`                    Returned point.

**Result**                  Returns 0 if no error, or `grfErrBadParam` if an error occurs.

**See Also**                [GrfAddPoint](#), [GrfGetNumPoints](#)

## Graffiti Manager

### Graffiti Manager Functions

---

## GrfGetState

<b>Purpose</b>	Return the current Graffiti shift state.								
<b>Declared In</b>	<code>Graffiti.h</code>								
<b>Prototype</b>	<pre>Err GrfGetState (Boolean *capsLockP, Boolean *numLockP, UInt16 *tempShiftP, Boolean *autoShiftedP)</pre>								
<b>Parameters</b>	<table><tr><td><code>capsLockP</code></td><td>Returns <code>true</code> if caps lock on.</td></tr><tr><td><code>numLockP</code></td><td>Returns <code>true</code> if num lock on.</td></tr><tr><td><code>tempShiftP</code></td><td>Current temporary shift.</td></tr><tr><td><code>autoShiftedP</code></td><td>Returns <code>TRUE</code> if shift not set by the user but by the system, for example, at the beginning of a line.</td></tr></table>	<code>capsLockP</code>	Returns <code>true</code> if caps lock on.	<code>numLockP</code>	Returns <code>true</code> if num lock on.	<code>tempShiftP</code>	Current temporary shift.	<code>autoShiftedP</code>	Returns <code>TRUE</code> if shift not set by the user but by the system, for example, at the beginning of a line.
<code>capsLockP</code>	Returns <code>true</code> if caps lock on.								
<code>numLockP</code>	Returns <code>true</code> if num lock on.								
<code>tempShiftP</code>	Current temporary shift.								
<code>autoShiftedP</code>	Returns <code>TRUE</code> if shift not set by the user but by the system, for example, at the beginning of a line.								
<b>Result</b>	Always returns 0.								
<b>Compatibility</b>	Palm OS® 2.0 and later has more user-friendly auto shifting. It uses an upper case letter under these conditions: <ul style="list-style-type: none"><li>• after an empty field</li><li>• after a period or other sentence terminator (such as ? or !).</li><li>• after two spaces</li></ul>								
<b>See Also</b>	<a href="#">GrfSetState</a>								

## GrfInitState

- Purpose** Reinitialize the Graffiti dictionary state.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfInitState (void)`
- Parameters** None.
- Result** Always returns 0.
- See Also** [GrfGetState](#), [GrfSetState](#)

## GrfMatch

- Purpose** Recognize the current stroke in the Graffiti point buffer and return with the recognized text.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfMatch (UInt16 *flagsP, void *dataPtrP, UInt16 *dataLenP, UInt16 *uncertainLenP, GrfMatchInfoPtr matchInfoP)`
- Parameters**
- |                            |   |
|----------------------------|---|
| <code>flagsP</code>        | Glyph flags are returned here.  |
| <code>dataPtrP</code>      | Return text is placed here.   |
| <code>dataLenP</code>      | Size of <code>dataPtrP</code> on exit; number of characters returned on exit. |
| <code>uncertainLenP</code> | Return number of uncertain characters.  |
| <code>matchInfoP</code>    | Array of <code>grfMaxMatches</code> , or NULL.                                |
- Result** Returns 0 if no error, or `grfErrNoGlyphTable`, `grfErrNoDictionary`, or `grfErrNoMapping` if an error occurs.
- See Also** [GrfAddPoint](#), [GrfFlushPoints](#)

## Graffiti Manager

### Graffiti Manager Functions

---

## GrfMatchGlyph

- Purpose** Recognize the current stroke as a glyph.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfMatchGlyph (GrfMatchInfoPtr matchInfoP, Int16 maxUncertainty, UInt16 maxMatches)`
- Parameters**
- `matchInfoP` Pointer to array of matches to fill in.
  - `maxUncertainty` Maximum number of errors to tolerate.
  - `maxMatches` Size of `matchInfoP` array.
- Result** Returns 0 if no error, or `grfErrNoGlyphTable` if an error occurs.
- See Also** [GrfMatch](#)

## GrfProcessStroke

- Purpose** Translate a stroke to keyboard events using Graffiti.
- Declared In** `Graffiti.h`
- Prototype** `Err GrfProcessStroke (PointType *startPtP, PointType *endPtP, Boolean upShift)`

**Parameters**

<code>startPtP</code>	Start point of stroke.
<code>endPtP</code>	End point of stroke.
<code>upShift</code>	Set to <code>true</code> to feed an artificial upshift into the engine.

**Result** Returns 0 if recognized.

**Comments** Called by `SysHandleEvent` when a `penUpEvent` is detected in the writing area. This routine recognizes the stroke and sends the recognized characters into the key queue. It also flushes the stroke out of the pen queue after recognition.

**See Also** [SysHandleEvent](#)

## GrfSetState

**Purpose** Set the current shift state of Graffiti.

**Declared In** `Graffiti.h`

**Prototype** `Err GrfSetState (Boolean capsLock, Boolean numLock, Boolean upperShift)`

**Parameters**

<code>capsLock</code>	Set to <code>true</code> to turn on caps lock.
<code>numLock</code>	Set to <code>true</code> to turn on num lock.
<code>upperShift</code>	Set to <code>true</code> to put into upper shift.

**Result** Always returns 0.

**See Also** [GrfGetState](#)

## **Graffiti Manager**

### *Graffiti Manager Functions*

---

# Helper API

---

This chapter describes the Helper API declared in the header files `Helper.h` and `HelperServiceClass.h`. The Helper API is used when an application broadcasts a [sysNotifyHelperEvent](#) to all interested parties. The broadcaster of the notification and the notification clients (called **helpers**) use the Helper APIs to communicate with each other. The chapter discusses the following topics:

- [Helper Data Structures](#)
- [Helper Constants](#)

For more information on using the Helper API, see the section “[Helper Notifications](#)” on page 38 of the *Palm OS Programmer’s Companion*, vol. I.

## Helper Data Structures

### HelperNotifyEnumerateListType

The `HelperNotifyEnumerateListType` provides the broadcaster of the helper notification with information about the services that the helper can provide. This structure is used as the data field of the [HelperNotifyEventType](#) structure when the action code is `kHelperNotifyActionCodeEnumerate`.

```
typedef struct HelperNotifyEnumerateListTypeTag
{
    struct HelperNotifyEnumerateListTypeTag
        *nextP;
    Char helperAppName[kHelperAppMaxNameSize];
    Char actionName[kHelperAppMaxActionNameSize];
    UInt32 helperAppID;
    UInt32 serviceClassID;
} HelperNotifyEnumerateListType;
```

## Helper API

### Helper Data Structures

---

Note that the helper allocates this structure and then adds it to the linked list of structures pointed to by `notifyDetailsP->data.enumerateP` in the [SysNotifyParamType](#) that is sent to the helper. The helper should allocate one structure per supported service.

Even though the helper allocates this structure, the helper is not responsible for freeing the structure. Instead, the application that broadcast the notification must free the structure.

#### Field Descriptions

<code>nextP</code>	A pointer to the next element in the list or NULL to signal the end of the list.
<code>helperAppName</code>	A null-terminated string containing the name of the helper application, suitable for display in the user interface. If more than one application can perform the same service, this name is displayed as one of the choices in a pop-up list.
<code>actionName</code>	A null-terminated string containing the name of the service that can be performed, suitable for display in the user interface. The action name should be short enough to display on a button.
<code>helperAppID</code>	The helper's creator ID or any other ID that uniquely identifies the helper.
<code>serviceClassID</code>	The ID of the service that the helper performs. See <a href="#">Helper Service Class IDs</a> .

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## HelperNotifyEventType

The `HelperNotifyEventType` structure contains all data associated with a helper notification ([`sysNotifyHelperEvent`](#)). A pointer to this structure is passed as the `notifyDetailsP` field in the [`SysNotifyParamType`](#) for that notification.

```
typedef struct HelperNotifyEventTypeTag {
    UInt16 version;
    HelperNotifyActionCodeType actionCode;
    union {
        struct HelperNotifyEnumerateListTypeTag
            *enumerateP;
        struct HelperNotifyValidateTypeTag
            *validateP;
        struct HelperNotifyExecuteTypeTag
            *executeP;
    } data;
} HelperNotifyEventType;
```

### Field Descriptions

<code>version</code>	The version number for this structure. The current version is 1.
<code>actionCode</code>	The action that the helper application should perform. See <a href="#">Table 35.1</a> .
<code>data</code>	Data specific to the action code. See <a href="#">Table 35.1</a> .

The `HelperNotifyEventType` structure specifies which action is to be performed and contains data necessary for that action. All actions have some common data. Actions also have data specific to that action. The specific data uses a union that is part of the `HelperNotifyEventType` structure.

**Table 35.1 Helper action codes**

<b>Action Code</b>	<b>data Type</b>	<b>Description</b>
kHelperNotify ActionCode Enumerate	<a href="#">HelperNotifyEnumerateListType</a>	Send a list of available services.
kHelperNotify ActionCode Validate	<a href="#">HelperNotifyValidateType</a>	Validate the input data for the specified service.
kHelperNotify ActionCode Execute	<a href="#">HelperNotifyExecuteType</a>	Perform the specified service.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **HelperNotifyExecuteType**

The `HelperNotifyExecuteType` structure identifies the service to perform and contains the data necessary to perform that service. This structure is used as the data field of the [HelperNotifyEventType](#) structure when the action code is `kHelperNotifyActionCodeExecute`.

```
typedef struct HelperNotifyExecuteTypeTag {
    UInt32  serviceClassID;
    UInt32  helperAppID;
    Char  *dataP;
    Char  *displayName;
    void  *detailsP;
    Err  err;
} HelperNotifyExecuteType;
```

### Field Descriptions

<code>serviceClassID</code>	The ID of the service to be performed. See <a href="#">Helper Service Class IDs</a> .
<code>helperAppID</code>	The unique ID of the helper; a value of 0 indicates that any available helper for the specified service class should perform the service.
<code>dataP</code>	A null-terminated string specific to this service, such as a phone number for the dial service or an email address for the email service. See <a href="#">Table 35.2</a> . Multiple fields must be separated by semicolons (;).
<code>displayName</code>	A null-terminated string containing an optional, human-readable description of the string in <code>dataP</code> . For example, if <code>dataP</code> contains a phone number, this field might contain the name of the person at that number.
<code>detailsP</code>	A pointer to a data structure containing extra information that this service requires. See <a href="#">Table 35.2</a> . If the service does not require extra information, this field is <code>NULL</code> .
<code>err</code>	An error code that indicates if the service was performed successfully or not. If the service was successful, this field contains <code>errNone</code> , and the <code>handled</code> field in the notification data structure should be set to <code>true</code> .

The following table lists the Palm OS-defined values for the service class ID and for each service, shows what value `dataP` contains and what type of structure `detailsP` points to.

**Table 35.2 HelperNotifyExecuteType values**

<b>Service Class ID</b>	<b>dataP Value</b>	<b>detailsP Value</b>
kHelper ServiceClassID VoiceDial	The telephone number to dial	NULL
kHelper ServiceClassID EMail	The email address to which the message is to be sent	<a href="#">HelperServiceEMailDetailsType</a>
kHelper ServiceClassID SMS	The SMS mailbox number to which the message is to be sent	<a href="#">HelperServiceSMSDetailsType</a>
kHelper ServiceClassID Fax	The fax number to which the fax is to be sent	NULL

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **HelperNotifyValidateType**

The `HelperNotifyValidateType` structure identifies a service that should be validated and the helper that should validate it. This structure is used as the data field of the [HelperNotifyEventType](#) structure when the action code is `kHelperNotifyActionCodeValidate`.

```
typedef struct HelperNotifyValidateTypeTag {  
    UInt32 serviceClassID;  
    UInt32 helperAppID;  
} HelperNotifyValidateType;
```

### Field Descriptions

- `serviceClassID` The ID of the service to be validated. See [Helper Service Class IDs](#).
- `helperAppID` The creator ID of the helper application. 0 indicates that any available helper for the specified service should respond. If nonzero, only the helper with the matching creator ID should respond.

The helper returns `true` in the handled field of the [SysNotifyParamType](#) structure to indicate that the service can be performed or `false` to indicate that the service cannot be performed.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### HelperServiceEMailDetailsType

The `HelperServiceEMailDetailsType` structure provides additional data for the email service. It is used as the `detailsP` field in the [HelperNotifyExecuteType](#) when the service class ID is `kHelperServiceClassIDEMail`.

```
typedef struct _HelperServiceEMailDetailsType
{
    UInt16 version;
    Char *cc;
    Char *subject;
    Char *message;
} HelperServiceEMailDetailsType;
```

### Field Descriptions

- `version` The version number for this structure. The current version is 1.
- `cc` A null-terminated string containing an email address that should be sent a carbon copy of the message. Multiple addresses are separated by a semi-colon (;). May be `NULL` if there are no email addresses to carbon copy.

## Helper API

### Helper Constants

---

`subject` A null-terminated string containing the subject line. May be NULL.

`message` Initial message body string or NULL.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

### HelperServiceSMSDetailsType

The `HelperServiceSMSDetailsType` structure provides the SMS message to be sent. It is used as the `detailsP` field in the [HelperNotifyExecuteType](#) when the service class ID is `kHelperServiceClassIDSMS`.

```
typedef struct _HelperServiceSMSDetailsType {
    UInt16 version;
    Char *message;
} HelperServiceSMSDetailsType;
```

#### Field Descriptions

`version` The version number for this structure. The current version is 1.

`message` A null-terminated string containing the body of the message to be sent, or NULL.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## Helper Constants

### Helper Service Class IDs

The header file `HelperServiceClass.h` defines the constants listed in [Table 35.3](#) as service class IDs. Third party developers may define their own service classes. To do so, you must register a 32-bit identifier with PalmSource, Inc. on this web site:

<http://www.palmos.com/dev/creatorid/>

Alternatively, you can use a creator ID that you already own.

**Table 35.3 Service class ID constants**

<b>Constant</b>	<b>Value</b>	<b>Description</b>
kHelperServiceClassIDVoiceDial	'voic'	Dial a phone number for a voice telephone call.
kHelperServiceClassIDEmail	'mail'	Send an email message.
kHelperServiceClassIDSMS	'sms_'	Send an SMS message.
kHelperServiceClassIDFax	'fax_'	Send a fax.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **Helper API**

*Helper Constants*

---

# Key Manager

---

This chapter provides reference material for the key manager. The key manager API is declared in the header file `KeyMgr.h`.

For more information on the key manager, see “[The Key Manager](#)” on page 62 of the *Palm OS Programmer’s Companion*, vol. I.

## Key Manager Functions

### KeyCurrentState

<b>Purpose</b>	Return bit field with bits set for each key that is currently depressed.
<b>Declared In</b>	<code>KeyMgr.h</code>
<b>Prototype</b>	<code>UInt32 KeyCurrentState (void)</code>
<b>Parameters</b>	None.
<b>Result</b>	Returns a <code>UInt32</code> with bits set for keys that are depressed. See <code>keyBitPower</code> , <code>keyBitPageUp</code> , <code>keyBitPageDown</code> , etc., in <code>KeyMgr.h</code> .
<b>Comments</b>	Called by applications that need to poll the keys.
<b>See Also</b>	<a href="#">KeyRates</a>

## Key Manager

### Key Manager Functions

---

## KeyRates

<b>Purpose</b>	Get or set the key repeat rates.										
<b>Declared In</b>	KeyMgr.h										
<b>Prototype</b>	Err KeyRates (Boolean set, UInt16* initDelayP, UInt16* periodP, UInt16* doubleTapDelayP, Boolean* queueAheadP)										
<b>Parameters</b>	<table><tr><td>set</td><td>If true, settings are changed; if false, current settings are returned.</td></tr><tr><td>initDelayP</td><td>Initial delay in ticks for a auto-repeat event.</td></tr><tr><td>periodP</td><td>Auto-repeat rate specified as period in ticks.</td></tr><tr><td>doubleTapDelayP</td><td>Maximum double-tap delay, in ticks.</td></tr><tr><td>queueAheadP</td><td>If true, auto-repeating keeps queueing up key events if the queue has keys in it. If false, auto-repeat doesn't enqueue keys unless the queue is already empty.</td></tr></table>	set	If true, settings are changed; if false, current settings are returned.	initDelayP	Initial delay in ticks for a auto-repeat event.	periodP	Auto-repeat rate specified as period in ticks.	doubleTapDelayP	Maximum double-tap delay, in ticks.	queueAheadP	If true, auto-repeating keeps queueing up key events if the queue has keys in it. If false, auto-repeat doesn't enqueue keys unless the queue is already empty.
set	If true, settings are changed; if false, current settings are returned.										
initDelayP	Initial delay in ticks for a auto-repeat event.										
periodP	Auto-repeat rate specified as period in ticks.										
doubleTapDelayP	Maximum double-tap delay, in ticks.										
queueAheadP	If true, auto-repeating keeps queueing up key events if the queue has keys in it. If false, auto-repeat doesn't enqueue keys unless the queue is already empty.										
<b>Result</b>	Returns 0 if no error.										
<b>See Also</b>	<a href="#">KeyCurrentState</a>										

## KeySetMask

- Purpose** Specify which keys generate `keyDownEvents`.  
You can specify this either by using this function or by using the `poweredOnKeyMask` modifier.
- Declared In** `KeyMgr.h`
- Prototype** `UInt32 KeySetMask (UInt32 keyMask)`
- Parameters** `keyMask` Mask with bits set for those keys to generate `keyDownEvents` for.
- Result** Returns the old `keyMask`.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## **Key Manager**

### *Key Manager Functions*

---

# Locale Manager

---

This chapter describes the Locale Manager API as described in the header files `LocaleMgr.h`, `Localize.h`, and `PalmLocale.h`. It discusses the following topics:

- [Locale Manager Data Types](#)
- [Locale Manager Constants](#)
- [Locale Manager Functions](#)

For more information on the Locale Manager, see the chapter “[Localized Applications](#)” on page 363 of the *Palm OS Programmer’s Companion*, vol. I.

## Locale Manager Data Types

### CountryType

The `CountryType` defines a country code. The [Country Constants](#) in `PalmLocale.h` define the possible values for `CountryType` variables.

```
typedef UInt8 CountryType;
```

**Compatibility** Prior to version 4.0, `CountryType` was an enum in `Preferences.h` that defined only 33 country codes. The Palm OS® 4.0 definition of `CountryType` is compatible with the previous definition.

### LanguageType

The `LanguageType` defines a language code. The [Language Constants](#) in `PalmLocale.h` define the possible values for `LanguageType` variables.

## Locale Manager

### Locale Manager Data Types

---

```
typedef UInt8 LanguageType;
```

**Compatibility** The `LanguageType` definition was added in Palm OS 3.5. Prior to version 4.0, `LanguageType` was an enum in `Preferences.h` that defined only eight language codes. The Palm OS 4.0 definition of `LanguageType` is compatible with the previous definition.

## LmLocaleType

The `LmLocaleType` struct defines the country and language used in a locale.

```
struct _LmLocaleType {
    UInt16      language;
    UInt16      country;
};
typedef struct _LmLocaleType LmLocaleType;
```

### Field Descriptions

`language` One of the [Language Constants](#). This value identifies the language spoken in the current locale.

`country` One of the [Country Constants](#). This value identifies the locale's country, which helps to identify the language dialect. For example, a language of `lEnglish` specifies a different dialect if the country is `cUnitedKingdom` than if it is `cUnitedStates`.

Note that the `language` and `country` fields are type `UInt16` instead of `LanguageType` and `CountryType`.

**Compatibility** The `LmLocaleType` is defined only if [4.0 New Feature Set](#) is present. It supersedes the `OmLocaleType` that was introduced with Palm OS 3.5. `LmLocaleType` is bit-compatible with `OmLocaleType`.

## NumberFormatType

The `NumberFormatType` enum specifies how numbers are formatted. You can pass a `NumberFormatType` value to

[LocGetNumberSeparators](#) and receive the appropriate separator characters for thousands and decimals.

```
typedef enum {
    nfCommaPeriod,
    nfPeriodComma,
    nfSpaceComma,
    nfApostrophePeriod,
    nfApostropheComma
} NumberFormatType;
```

### Value Descriptions

<code>nfCommaPeriod</code>	Uses a comma (,) as the thousands separator and a period (.) as the decimal separator.
<code>nfPeriodComma</code>	Uses a period as the thousands separator and a comma as the decimal separator.
<code>nfSpaceComma</code>	Uses a space ( ) as the thousands separator and a comma as the decimal separator.
<code>nfApostrophePeriod</code>	Uses an apostrophe (') as the thousands separator and a period as the decimal separator.
<code>nfApostropheComma</code>	Uses an apostrophe as the thousands separator and a comma as the decimal separator.

## Locale Manager Constants

### Character Encoding Constants

The `PalmLocale.h` file defines several character encoding constants that are used as values of [CharEncodingType](#) variables. The character encoding constants generally follow the format:

```
charEncodingName
```

where *Name* is the name of the character encoding.

## Locale Manager

### *Locale Manager Constants*

---

The following table shows examples of the character encoding constants. For a complete list, see the `PalmLocale.h` file.

<b>Constant</b>	<b>Description</b>
<code>charEncodingUnknown</code>	Unknown to this version of Palm OS®
<code>charEncodingAscii</code>	ISO 646-1991
<code>charEncodingISO8859_1</code>	ISO 8859 Part 1 (also known as ISO Latin 1). This encoding is commonly used for the Roman alphabet
<code>charEncodingPalmLatin</code>	Palm OS version of Microsoft Windows code page 1252. This encoding is identical to code page 1252 with Palm-specific characters added in the control range.
<code>charEncodingShiftJIS</code>	Encoding for 0208-1990 with single-byte Japanese Katakana. This encoding is commonly used for Japanese alphabets.
<code>charEncodingPalmSJIS</code>	Palm OS version of Microsoft Windows code page 932. This encoding is identical to code page 932, with Palm-specific characters added in the control range and with a Yen symbol instead of the Reverse Solidus at location 0x5c.
<code>charEncodingCP1252</code>	Microsoft Windows extensions to ISO 8859 Part 1
<code>charEncodingCP932</code>	Microsoft Windows extensions to Shift JIS
<code>charEncodingUTF8</code>	Eight-bit safe encoding for Unicode

---

## Country Constants

The `PalmLocale.h` file defines several country constants that are used as values of [CountryType](#) variables. The country type constants have the following format:

*cCountryName*

where *CountryName* is the name of the country. There is one constant for each country identified in the ISO 3166 standard, which currently defines 239 countries.

The following table shows examples of the country type constants. For a complete list, see the `PalmLocale.h` file.

<b>Constant</b>	<b>Description</b>
<code>cAustralia</code>	Australia
<code>cAustria</code>	Austria
<code>cBelgium</code>	Belgium

## Language Constants

The `PalmLocale.h` file defines several language constants that are used as values of [LanguageType](#) variables. The language type constants have the following format:

*lLanguageName*

where *LanguageName* is the name of the language. There is one constant for each language specified in the ISO 639 standard, which currently defines 137 languages.

The following table shows examples of the language type constants. For a complete list, see the `PalmLocale.h` file.

<b>Constant</b>	<b>Description</b>
<code>lEnglish</code>	English
<code>lFrench</code>	French
<code>lGerman</code>	German

## Locale Manager

### Locale Manager Functions

---

## Locale Manager Size Constants

You can use the Locale Manager size constants to determine the size of strings to allocate for some of the locale settings.

---

**NOTE:** The variables in the table below do not count the terminating null character. Therefore, you need to allocate a string of size `kMaxCountryNameLen+1` to hold a country name, for example.

---

Constant	Value	Description
<code>kMaxCountryNameLen</code>	19	The maximum length of a country name string.
<code>kMaxCurrencyNameLen</code>	19	The maximum length of a currency name string.
<code>kMaxCurrencySymbolLen</code>	5	The maximum length of a currency symbol string.

---

## Locale Manager Functions

### LmGetLocaleSetting

**Purpose** Return the requested setting for a given locale.

**Declared In** `LocaleMgr.h`

**Prototype** `Err LmGetLocaleSetting (UInt16 iLocaleIndex, LmLocaleSettingChoice iChoice, void *oValue, UInt16 iValueSize)`

**Parameters** `-> iLocaleIndex` Index of the locale whose settings you want to retrieve.

`-> iChoice` The setting you want to retrieve. This is a constant in the form `lmChoiceSettingName`. See [Table 37.1](#) for a list of possible values.

<- oValue            The value of the iChoice setting. The size of this buffer depends on the value of iChoice, as shown in [Table 37.1](#).

-> iValueSize        The size of the oValue buffer.

**Result**            Returns one of the following values:

errNone              Success.

lmErrBadLocaleIndex  
                      iLocaleIndex is out of range.

lmErrSettingDataOverflow  
                      The oValue buffer is too small to hold the setting's value.

lmErrBadLocaleSettingChoice  
                      The iChoice parameter contains an unknown or unsupported value.

**Comments**        This function accesses the private locale system resource and returns the requested information in the oValue parameter. The size and type of the oValue parameter depend on which setting you want to retrieve. [Table 37.1](#) lists and describes the possible settings and the type of data returned in oValue for each setting. For fixed-size values, make sure that oValue is no larger than the returned value.

This function returns the default settings for the locale. Users can override many of the locale settings using the Preferences application. Applications should always honor the user's preferences rather than the locale defaults. For this reason, it's recommended that if a corresponding system preference is available, you should check it instead (using [PrefGetPreference](#)). Use LmGetLocaleSetting only if you want to retrieve values that the user cannot override (such as the country name or currency symbol) or if you want to retrieve information about a locale other than the current locale.

## Locale Manager

### Locale Manager Functions

---

**Table 37.1 LmGetLocaleSetting choices and sizes**

<b>ImChoice...</b>	<b>oValue Data Type</b>	<b>Description</b>
CountryName	String buffer of size kMaxCountryNameLen+1 bytes	The name of the locale's country.
CurrencyName	String buffer of size kMaxCurrencyNameLen+1 bytes	The name of the currency used in this locale.
CurrencySymbol	String buffer of size kMaxCurrencySymbolLen+1 bytes	The symbol used to denote monetary values in this locale.
CurrencyDecimal Places	UInt16	The number of decimal places that monetary values are typically given.
DateFormat	<a href="#">DateFormatType</a>	The short date format used in this locale. For example:  95/12/31
Locale	<a href="#">LmLocaleType</a>	A structure containing the locale's language and country codes.
LongDateFormat	<a href="#">DateFormatType</a>	The long date format used in this locale. For example:  31 Dec 1995
MeasurementSystem	<a href="#">MeasurementSystemType</a>	The measurement system (metric system or English system) used in this locale.
NumberFormat	<a href="#">NumberFormatType</a>	The format used for numbers, with regards to the thousands separator and the decimal point, in this locale.

**Table 37.1 LmGetLocaleSetting choices and sizes (*continued*)**

ImChoice...	oValue Data Type	Description
TimeFormat	<a href="#">TimeFormatType</a>	The format used for time values in this locale.
TimeZone	Int16	The locale's default time zone given as the number of minutes east of Greenwich Mean Time (GMT).
UniqueCurrencySymbol	String buffer of size kMaxCurrencySymbolLen+1 bytes	A unique symbol for monetary values.  For example, the symbol \$ is used both for US dollars and Portuguese escudos. The unique currency symbol for US dollars is US\$.
WeekStartDay	UInt16	The first day of the week (Sunday or Monday) in this locale. Days of the week are numbered from 0 to 6 starting with Sunday = 0.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `LmGlueGetLocaleSetting`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [LmGetNumLocales](#), [LmLocaleToIndex](#)

## Locale Manager

### Locale Manager Functions

---

## LmGetNumLocales

<b>Purpose</b>	Return the number of known locales.
<b>Declared In</b>	LocaleMgr.h
<b>Prototype</b>	UInt16 LmGetNumLocales (void)
<b>Parameters</b>	None.
<b>Result</b>	Returns the number of locales that the locale system resource defines.
<b>Comments</b>	<p>Use this function to obtain the range of possible values that you can pass as an index to <a href="#">LmGetLocaleSetting</a>. If <code>LmGetNumLocales</code> returns 3, then <code>LmGetLocaleSetting</code> accepts indexes in the range of 0 to 2.</p> <p>This function returns only the number of locales for which the ROM has locale information. It does not return the number of locales that could possibly be defined. For example, the system resource currently contains no locale whose language is <code>lHebrew</code> and country is <code>cIsrael</code>, even though that is a valid locale.</p>
<b>Compatibility</b>	Implemented only if <a href="#">4.0 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>LmGlueGetNumLocales</code> . For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>

## LmLocaleToIndex

- Purpose** Convert an [LmLocaleType](#) to an index.
- Declared In** `LocaleMgr.h`
- Prototype** `Err LmLocaleToIndex (const LmLocaleType *iLocale, UInt16 *oLocaleIndex)`
- Parameters** `-> iLocale` The locale to convert.  
`<- oLocaleIndex` The index of `iLocale` upon return.
- Result** Returns `errNone` upon success or `lmErrUnknownLocale` if the locale could not be found.
- Comments** You can use this function to obtain a valid index to pass to [LmGetLocaleSetting](#). For example, you might use the Overlay Manager routine [OmGetSystemLocale](#) to return the locale used on the current system and then pass that locale to this function to obtain its index.
- ```
LmLocaleType locale;  
Char oValue[kMaxCurrencySymbolLen+1];  
UInt16 index;  
  
OmGetSystemLocale(&locale);  
LmLocaleToIndex(&locale, &index);  
LmGetLocaleSetting(index,  
    lmChoiceCurrencySymbol, oValue,  
    sizeof(oValue));
```
- The `LmLocaleType` that is passed in `iLocale` can use the constants `lmAnyCountry` or `lmAnyLanguage` as wildcards. For example, if the country is `lmAnyCountry`, `LmLocaleToIndex` returns the index of the first locale that matches the language.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the `PalmOSGlue` library and call

## Locale Manager

### *Locale Manager Functions*

---

LmGlueLocaleToIndex. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

# Memory Manager

---

This chapter provides reference information for the memory manager. The memory manager API is declared in the header file `MemoryMgr.h`.

For more information on the memory manager, see the chapter “[Memory](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Memory Manager Functions

### MemCardInfo

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                     |              |                        |                                              |                         |                                              |                       |                                    |                      |                                          |                       |                                     |                       |                                     |

## Memory Manager

### Memory Manager Functions

---

`freeBytesP`      Pointer to free byte-count variable, or 0.

**Result**      Returns 0 if no error.

**Comments**      Pass 0 for those variables that you don't want returned.

## MemCmp

**Purpose**      Compare two blocks of memory.

---

**NOTE:**      Blocks are compared as unsigned bytes.

---

**Declared In**      `MemoryMgr.h`

**Prototype**      `Int16 MemCmp (const void* s1, const void* s2, Int32 numBytes)`

**Parameters**      `s1, s2`      Pointers to block of memory.  
                         `numBytes`      Number of bytes to compare.

**Result**      Zero if they match, non-zero if not:  
                 + if `s1 > s2`  
                 - if `s1 < s2`

**Compatibility**      Implemented only if [2.0 New Feature Set](#) is present.

`MemCmp` can be used to test the equality of blocks in memory on all versions that support `MemCmp`; however, testing the sort ordering of blocks in memory works reliably only on Palm OS® versions 3.5 and higher. On versions earlier than 3.2, `MemCmp` always returns a positive value if the blocks are unequal. On versions 3.2 and 3.3, `MemCmp` reliably returns positive to indicate `s1 > s2` and negative to indicate `s1 < s2` **only** if the characters that differ are less than 128 apart. If the difference is greater than that, `MemCmp` may return positive when it should return negative and vice versa.

## MemDebugMode

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the current debugging mode of the memory manager.               |
| <b>Declared In</b> | MemoryMgr.h                                                            |
| <b>Prototype</b>   | UInt16 MemDebugMode (void)                                             |
| <b>Parameters</b>  | No parameters.                                                         |
| <b>Result</b>      | Returns debug flags as described for <a href="#">MemSetDebugMode</a> . |

## MemHandleCardNo

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the card number a chunk resides in.                                         |
| <b>Declared In</b> | MemoryMgr.h                                                                        |
| <b>Prototype</b>   | UInt16 MemHandleCardNo (MemHandle h)                                               |
| <b>Parameters</b>  | -> h                      Chunk handle.                                            |
| <b>Result</b>      | Returns the card number.                                                           |
| <b>Comments</b>    | Call this routine to retrieve the card number (0 or 1) a movable chunk resides on. |
| <b>See Also</b>    | <a href="#">MemPtrCardNo</a>                                                       |

## Memory Manager

### Memory Manager Functions

---

#### MemHandleDataStorage

- Purpose** Return `true` if the given handle is part of a data storage heap. If not, it's a handle in the dynamic heap.
- Declared In** `MemoryMgr.h`
- Prototype** `Boolean MemHandleDataStorage (MemHandle h)`
- Parameters** `-> h` Chunk handle.
- Result** Returns `true` if the handle is part of a data storage heap.
- Comments** Called by Fields package routines to determine if they need to worry about data storage write-protection when editing a text field.
- See Also** [MemPtrDataStorage](#)

#### MemHandleFree

- Purpose** Dispose of a movable chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemHandleFree (MemHandle h)`
- Parameters** `-> h` Chunk handle.
- Result** Returns 0 if no error, or `memErrInvalidParam` if an error occurs.
- Comments** Call this routine to dispose of a movable chunk.
- See Also** [MemHandleNew](#)

## MemHandleHeapID

- Purpose** Return the heap ID of a chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `UInt16 MemHandleHeapID (MemHandle h)`
- Parameters** `-> h` Chunk handle.
- Result** Returns the heap ID of a chunk.
- Comments** Call this routine to get the heap ID of the heap a chunk resides in.
- See Also** [MemPtrHeapID](#)

## MemHandleLock

- Purpose** Lock a chunk and obtain a pointer to the chunk's data.
- Declared In** `MemoryMgr.h`
- Prototype** `MemPtr MemHandleLock (MemHandle h)`
- Parameters** `-> h` Chunk handle.
- Result** Returns a pointer to the chunk.
- Comments** Call this routine to lock a chunk and obtain a pointer to the chunk. `MemHandleLock` and `MemHandleUnlock` should be used in pairs.
- See Also** [MemHandleNew](#), [MemHandleUnlock](#)

## Memory Manager

### Memory Manager Functions

---

#### MemHandleNew

- Purpose** Allocate a new movable chunk in the dynamic heap and returns a handle to it.
- Declared In** `MemoryMgr.h`
- Prototype** `MemHandle MemHandleNew (UInt32 size)`
- Parameters** `-> size` The desired size of the chunk.
- Result** Returns a handle to the new chunk, or 0 if unsuccessful.
- Comments** Use this call to allocate dynamic memory. Before you can write data to the memory chunk that `MemHandleNew` allocates, you must call [MemHandleLock](#) to lock the chunk and get a pointer to it.
- See Also** [MemPtrFree](#), [MemPtrNew](#), [MemHandleFree](#), [MemHandleLock](#)

#### MemHandleResize

- Purpose** Resize a chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemHandleResize (MemHandle h, UInt32 newSize)`
- Parameters** `-> h` Chunk handle.  
`-> newSize` The new desired size.
- Result** 0 No error.  
`memErrInvalidParam` Invalid parameter passed.  
`memErrNotEnoughSpace` Not enough free space in heap to grow chunk.

memErrChunkLocked

Can't grow chunk because it's locked.

**Comments** Call this routine to resize a chunk. This routine is always successful when shrinking the size of a chunk, even if the chunk is locked. When growing a chunk, it first attempts to grab free space immediately following the chunk so that the chunk does not have to move. If the chunk has to move to another free area of the heap to grow, it must be movable and have a lock count of 0.

On devices running version 2.0 or earlier of Palm OS, the MemHandleResize function tries to resize the chunk only within the same heap, whereas [DmResizeRecord](#) will look for space in other data heaps if it can't find enough space in the original heap.

**See Also** [MemHandleNew](#), [MemHandleSize](#)

## MemHandleSetOwner

**Purpose** Set the owner ID of a chunk.

**Declared In** MemoryMgr.h

**Prototype** Err MemHandleSetOwner (MemHandle h, UInt16 owner)

**Parameters**

|          |                                                                                |
|----------|--------------------------------------------------------------------------------|
| -> h     | Chunk handle.                                                                  |
| -> owner | New owner ID of the chunk. Specify 0 to set the owner to the operating system. |

**Result** Returns 0 if no error, or memErrInvalidParam if an error occurs.

**Comments** When you allocate a parameter block to pass to [SysUIAppSwitch](#) or [SysAppLaunch](#), you must call [MemPtrSetOwner](#) to grant ownership of the parameter block chunk to the OS (your application is originally set as the owner). If the parameter block structure references any chunks by handle, you also must call MemHandleSetOwner to grant ownership of those blocks to the OS. If you don't change the ownership of these chunks, they will get

## Memory Manager

### Memory Manager Functions

---

freed before the application you're launching has a chance to use them.

## MemHandleSize

- Purpose** Return the requested size of a chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `UInt32 MemHandleSize (MemHandle h)`
- Parameters** `-> h` Chunk handle.
- Result** Returns the requested size of the chunk.
- Comments** Call this routine to get the size originally requested for a chunk.
- See Also** [MemHandleResize](#)

## MemHandleToLocalID

- Purpose** Convert a handle into a local chunk ID which is card relative.
- Declared In** `MemoryMgr.h`
- Prototype** `LocalID MemHandleToLocalID (MemHandle h)`
- Parameters** `-> h` Chunk handle.
- Result** Returns local ID, or NULL (0) if unsuccessful.
- Comments** Call this routine to convert a chunk handle to a local ID.
- See Also** [MemLocalIDToGlobal](#), [MemLocalIDToLockedPtr](#)

## MemHandleUnlock

|                    |                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Unlock a chunk given a chunk handle.                                                                                     |
| <b>Declared In</b> | MemoryMgr.h                                                                                                              |
| <b>Prototype</b>   | Err MemHandleUnlock (MemHandle h)                                                                                        |
| <b>Parameters</b>  | -> h                      The chunk handle.                                                                              |
| <b>Result</b>      | 0                              No error.<br>memErrInvalidParam              Invalid parameter passed.                    |
| <b>Comments</b>    | Call this routine to decrement the lock count for a chunk.<br>MemHandleLock and MemHandleUnlock should be used in pairs. |
| <b>See Also</b>    | <a href="#">MemHandleLock</a>                                                                                            |

## MemHeapCheck

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Purpose</b>     | Check validity of a given heap.                                |
| <b>Declared In</b> | MemoryMgr.h                                                    |
| <b>Prototype</b>   | Err MemHeapCheck (UInt16 heapID)                               |
| <b>Parameters</b>  | heapID                      ID of heap to check.               |
| <b>Result</b>      | Returns 0 if no error.                                         |
| <b>See Also</b>    | <a href="#">MemDebugMode</a> , <a href="#">MemSetDebugMode</a> |

## Memory Manager

### Memory Manager Functions

---

#### MemHeapCompact

- Purpose** Compact a heap.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemHeapCompact (UInt16 heapID)`
- Parameters** `-> heapID` ID of the heap to compact.
- Result** Always returns 0.
- Comments** Most applications never need to call this function explicitly. The system software calls this function at various times; for example, during memory allocation (if sufficient free space is not available) and during system reboot.
- Call this routine to compact a heap and merge all free space. This routine attempts to move all movable chunks to the start of the heap and merge all free space in the center of the heap.

#### MemHeapDynamic

- Purpose** Return `true` if the given heap is a dynamic heap.
- Declared In** `MemoryMgr.h`
- Prototype** `Boolean MemHeapDynamic (UInt16 heapID)`
- Parameters** `heapID` ID of the heap to be tested.
- Result** Returns `true` if dynamic, `false` if not.
- Comments** Dynamic heaps are used for volatile storage, application stacks, globals, and dynamically allocated memory.

---

**NOTE:** In Palm OS 3.5, the dynamic heap is sized based on the amount of memory available, and is generally larger than before.

---

**See Also** [MemNumHeaps](#), [MemHeapID](#)

## MemHeapFlags

**Purpose** Return the heap flags for a heap.

**Declared In** `MemoryMgr.h`

**Prototype** `UInt16 MemHeapFlags (UInt16 heapID)`

**Parameters** `-> heapID` ID of heap.

**Result** Returns the heap flags.

**Comments** Call this routine to retrieve the heap flags for a heap. The flags can be examined to determine if the heap is ROM based or not. ROM-based heaps have the `memHeapFlagReadOnly` bit set (the `memHeapFlagReadOnly` mask has a value of `0x0001`).

**See Also** [MemNumHeaps](#), [MemHeapID](#)

## MemHeapFreeBytes

**Purpose** Return the total number of free bytes in a heap and the size of the largest free chunk in the heap.

**Declared In** `MemoryMgr.h`

**Prototype** `Err MemHeapFreeBytes (UInt16 heapID, UInt32* freeP, UInt32* maxP)`

**Parameters** `-> heapID` ID of heap.

## Memory Manager

### Memory Manager Functions

---

<-> freeP      Pointer to a variable of type UInt32 for free bytes.

<-> maxP      Pointer to a variable of type UInt32 for max free chunk size. Do not pass NULL for this argument.

**Result**      Always returns 0.

**Comments**    This routine doesn't compact the heap but may be used to determine in advance whether an allocation request will succeed. Before allocating memory, call this function and test the value returned in maxP to determine whether enough free space to fulfill your allocation request exists. If not, you may make more space available by calling the [MemHeapCompact](#) function. Note that both [MemPtrNew](#) and [MemHandleNew](#) automatically compact the heap if necessary.

**See Also**    [MemHeapSize](#), [MemHeapID](#), [MemHeapCompact](#)

## MemHeapID

**Purpose**      Return the heap ID for a heap, given its index and the card number.

**Declared In**    MemoryMgr.h

**Prototype**    UInt16 MemHeapID (UInt16 cardNo, UInt16 heapIndex)

**Parameters**    -> cardNo      The card number, either 0 or 1.  
                  -> heapIndex    The heap index, anywhere from 0 to [MemNumHeaps](#) - 1.

**Result**      Returns the heap ID.

**Comments**    Call this routine to retrieve the heap ID of a heap, given the heap index and the card number. A heap ID must be used to obtain

information on a heap such as its size, free bytes, etc., and is also passed to any routines which manipulate heaps.

**See Also** [MemNumHeaps](#)

## **MemHeapScramble**

**Purpose** Scramble the specified heap.

**Declared In** `MemoryMgr.h`

**Prototype** `Err MemHeapScramble (UInt16 heapID)`

**Parameters** `heapID` ID of heap to scramble.

**Comments** The system attempts to move each movable chunk.  
Useful for debugging.

**Result** Always returns 0.

**See Also** [MemDebugMode](#), [MemSetDebugMode](#)

## **MemHeapSize**

**Purpose** Return the total size of a heap including the heap header.

**Declared In** `MemoryMgr.h`

**Prototype** `UInt32 MemHeapSize (UInt16 heapID)`

**Parameters** `-> heapID` ID of heap.

**Result** Returns the total size of the heap.

**See Also** [MemHeapFreeBytes](#), [MemHeapID](#)

## Memory Manager

### Memory Manager Functions

---

#### MemLocalIDKind

- Purpose** Return whether or not a local ID references a handle or a pointer.
- Declared In** `MemoryMgr.h`
- Prototype** `LocalIDKind MemLocalIDKind (LocalID local)`
- Parameters** `-> local` Local ID to query
- Result** Returns `LocalIDKind`, or a `memIDHandle` or `memIDPtr` (see `MemoryMgr.h`).
- Comments** This routine determines if the given local ID is to a nonmovable (`memIDPtr`) or movable (`memIDHandle`) chunk.

#### MemLocalIDToGlobal

- Purpose** Convert a local ID, which is card relative, into a global pointer in the designated card.
- Declared In** `MemoryMgr.h`
- Prototype** `MemPtr MemLocalIDToGlobal (LocalID local, UInt16 cardNo)`
- Parameters** `-> local` The local ID to convert.  
`-> cardNo` Memory card the chunk resides in.
- Result** Returns pointer or handle to chunk.
- See Also** [MemLocalIDKind](#), [MemLocalIDToLockedPtr](#)

## MemLocalIDToLockedPtr

- Purpose** Return a pointer to a chunk given its local ID and card number. If the local ID references a movable chunk handle, this routine automatically locks the chunk before returning.
- Declared In** `MemoryMgr.h`
- Prototype** `MemPtr MemLocalIDToLockedPtr (LocalID local, UInt16 cardNo)`
- Parameters**
- |                     |                 |
|---------------------|-----------------|
| <code>local</code>  | Local chunk ID. |
| <code>cardNo</code> | Card number.    |
- Result** Returns pointer to chunk, or 0 if an error occurs.
- See Also** [MemLocalIDToGlobal](#), [MemLocalIDToPtr](#), [MemLocalIDKind](#), [MemPtrToLocalID](#), [MemHandleToLocalID](#)

## MemLocalIDToPtr

- Purpose** Return pointer to chunk, given the local ID and card number.
- Declared In** `MemoryMgr.h`
- Prototype** `MemPtr MemLocalIDToPtr (LocalID local, UInt16 cardNo)`
- Parameters**
- |                           |                                   |
|---------------------------|-----------------------------------|
| <code>-&gt; local</code>  | Local ID to query.                |
| <code>-&gt; cardNo</code> | Card number the chunk resides in. |
- Result** Returns a pointer to the chunk, or 0 if error.
- Comments** If the local ID references a movable chunk and that chunk is **not** locked, this function returns 0 to indicate an error.
- See Also** [MemLocalIDToGlobal](#), [MemLocalIDToLockedPtr](#)

## Memory Manager

### Memory Manager Functions

---

#### MemMove

- Purpose** Move a range of memory to another range in the dynamic heap.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemMove (void* dstP, const void* sP, Int32 numBytes)`
- Parameters**
- |                       |                          |
|-----------------------|--------------------------|
| <code>dstP</code>     | Pointer to destination.  |
| <code>sP</code>       | Pointer to source.       |
| <code>numBytes</code> | Number of bytes to move. |
- Result** Always returns 0.
- Comments** Handles overlapping ranges.  
For operations where the destination is in a data heap, see [DmSet](#), [DmWrite](#), and related functions.

#### MemNumCards

- Purpose** Return the number of memory card slots in the system. Not all slots need to be populated.
- Declared In** `MemoryMgr.h`
- Prototype** `UInt16 MemNumCards (void)`
- Parameters** None.
- Result** Returns number of slots in the system.

## MemNumHeaps

|                    |                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return the number of heaps available on a particular card.                                                                                                                                                                                                                                                                                                                                                 |
| <b>Declared In</b> | MemoryMgr.h                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Prototype</b>   | UInt16 MemNumHeaps (UInt16 cardNo)                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | -> cardNo            The card number; either 0 or 1.                                                                                                                                                                                                                                                                                                                                                       |
| <b>Result</b>      | Number of heaps available, including ROM- and RAM-based heaps.                                                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>    | Call this routine to retrieve the total number of heaps on a memory card. The information can be obtained by calling <a href="#">MemHeapSize</a> , <a href="#">MemHeapFreeBytes</a> , and <a href="#">MemHeapFlags</a> on each heap using its heap ID. The heap ID is obtained by calling <a href="#">MemHeapID</a> with the card number and the heap index, which can be any value from 0 to MemNumHeaps. |

## MemNumRAMHeaps

|                    |                                                   |
|--------------------|---------------------------------------------------|
| <b>Purpose</b>     | Return the number of RAM heaps in the given card. |
| <b>Declared In</b> | MemoryMgr.h                                       |
| <b>Prototype</b>   | UInt16 MemNumRAMHeaps (UInt16 cardNo)             |
| <b>Parameters</b>  | cardNo            The card number.                |
| <b>Result</b>      | Returns the number of RAM heaps.                  |
| <b>See Also</b>    | <a href="#">MemNumCards</a>                       |

## Memory Manager

### Memory Manager Functions

---

#### MemPtrCardNo

- Purpose** Return the card number (0 or 1) a nonmovable chunk resides on.
- Declared In** `MemoryMgr.h`
- Prototype** `UInt16 MemPtrCardNo (MemPtr p)`
- Parameters** `-> p` Pointer to the chunk.
- Result** Returns the card number.
- See Also** [MemHandleCardNo](#)

#### MemPtrDataStorage

- Purpose** Return `true` if the given pointer is part of a data storage heap; if not, it is a pointer in the dynamic heap.
- Declared In** `MemoryMgr.h`
- Prototype** `Boolean MemPtrDataStorage (MemPtr p)`
- Parameters** `p` Pointer to a chunk.
- Result** Returns `true` if the chunk is part of a data storage heap.
- Comments** Called by Fields package to determine if it needs to worry about data storage write-protection when editing a text field.
- See Also** [MemHeapDynamic](#)

## **MemPtrFree**

|                    |                                                                                       |
|--------------------|---------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Macro to dispose of a chunk.                                                          |
| <b>Declared In</b> | MemoryMgr.h                                                                           |
| <b>Prototype</b>   | Err MemPtrFree (MemPtr p)                                                             |
| <b>Parameters</b>  | -> p                      Pointer to a chunk.                                         |
| <b>Result</b>      | 0                              If no error or memErrInvalidParam (invalid parameter). |
| <b>Comments</b>    | Call this routine to dispose of a nonmovable chunk.                                   |

## **MemPtrHeapID**

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Purpose</b>     | Return the heap ID of a chunk.                                       |
| <b>Declared In</b> | MemoryMgr.h                                                          |
| <b>Prototype</b>   | UInt16 MemPtrHeapID (MemPtr p)                                       |
| <b>Parameters</b>  | -> p                      Pointer to the chunk.                      |
| <b>Result</b>      | Returns the heap ID of a chunk.                                      |
| <b>Comments</b>    | Call this routine to get the heap ID of the heap a chunk resides in. |

## Memory Manager

### Memory Manager Functions

---

#### MemPtrNew

- Purpose** Allocate a new nonmovable chunk in the dynamic heap.
- Declared In** `MemoryMgr.h`
- Prototype** `MemPtr MemPtrNew (UInt32 size)`
- Parameters** `-> size` The desired size of the chunk.
- Result** Returns pointer to the new chunk, or 0 if unsuccessful.
- Comments** This routine allocates a nonmovable chunk in the dynamic heap and returns a pointer to the chunk. Applications can use it when allocating dynamic memory. Note that chunks range in size from 1 byte to slightly less than 64KB; you cannot allocate a single chunk larger than this.
- In Palm OS 3.5, the dynamic heap is sized based on the amount of memory available, and is generally larger than before.

---

**NOTE:** You cannot allocate a zero-size reference block.

---

#### MemPtrRecoverHandle

- Purpose** Recover the handle of a movable chunk, given a pointer to its data.
- Declared In** `MemoryMgr.h`
- Prototype** `MemHandle MemPtrRecoverHandle (MemPtr p)`
- Parameters** `-> p` Pointer to the chunk.
- Result** Returns the handle of the chunk, or 0 if unsuccessful.
- Comments** Don't call this function for pointers in ROM or nonmovable data chunks.

## MemPtrResize

- Purpose** Resize a chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemPtrResize (MemPtr p, UInt32 newSize)`
- Parameters**
- > `p` Pointer to the chunk.
  - > `newSize` The new desired size.
- Result** Returns 0 if no error, or `memErrNotEnoughSpace`, `memErrInvalidParam`, or `memErrChunkLocked` if an error occurs.
- Comments** Call this routine to resize a locked chunk. This routine is always successful when shrinking the size of a chunk. When growing a chunk, it attempts to use free space immediately following the chunk.
- See Also** [MemPtrSize](#), [MemHandleResize](#)

## MemPtrSetOwner

- Purpose** Set the owner ID of a chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemPtrSetOwner (MemPtr p, UInt16 owner)`
- Parameters**
- > `p` Pointer to the chunk.
  - > `owner` New owner ID of the chunk. Specify 0 to set the owner to the operating system.
- Result** Returns 0 if no error, or `memErrInvalidParam` if an error occurs.

## Memory Manager

### Memory Manager Functions

---

**Comments** When you allocate a parameter block to pass to [SysUIAppSwitch](#) or [SysAppLaunch](#), you must call `MemPtrSetOwner` or [MemHandleSetOwner](#) to grant ownership of the parameter block chunk, and any other chunks referenced in it, to the OS (your application is originally set as the owner). If you don't change the ownership of the parameter block, it will get freed before the application you're launching has a chance to use it.

### MemPtrSize

**Purpose** Return the size of a chunk.

**Declared In** `MemoryMgr.h`

**Prototype** `UInt32 MemPtrSize (MemPtr p)`

**Parameters** `-> p` Pointer to the chunk.

**Result** The requested size of the chunk.

**Comments** Call this routine to get the original requested size of a chunk.

### MemPtrToLocalID

**Purpose** Convert a pointer into a card-relative local chunk ID.

**Declared In** `MemoryMgr.h`

**Prototype** `LocalID MemPtrToLocalID (MemPtr p)`

**Parameters** `-> p` Pointer to a chunk.

**Result** Returns the local ID of the chunk.

**Comments** Call this routine to convert a chunk pointer to a local ID.

**See Also** [MemLocalIDToPtr](#)

## MemPtrUnlock

- Purpose** Unlock a chunk, given a pointer to the chunk.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemPtrUnlock (MemPtr p)`
- Parameters** `p` Pointer to a chunk.
- Result** 0 if no error, or `memErrInvalidParam` if an error occurs.
- Comments** A chunk must **not** be unlocked more times than it was locked.
- See Also** [MemHandleLock](#)

## MemSet

- Purpose** Set a memory range in a dynamic heap to a specific value.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemSet (void* dstP, Int32 numBytes, UInt8 value)`

## Memory Manager

### Memory Manager Functions

---

**Parameters**

|                       |                             |
|-----------------------|-----------------------------|
| <code>dstP</code>     | Pointer to the destination. |
| <code>numBytes</code> | Number of bytes to set.     |
| <code>value</code>    | Value to set.               |

**Result** Always returns 0.

**Comments** For operations where the destination is in a data heap, see [DmSet](#), [DmWrite](#), and related functions.

## MemSetDebugMode

**Purpose** Set the debugging mode of the memory manager.

**Declared In** `MemoryMgr.h`

**Prototype** `Err MemSetDebugMode (UInt16 flags)`

**Parameters**

|                    |              |
|--------------------|--------------|
| <code>flags</code> | Debug flags. |
|--------------------|--------------|

**Comments** Use the logical OR operator (`|`) to provide any combination of one, more, or none of the following flags:

```
memDebugModeCheckOnChange  
memDebugModeCheckOnAll  
memDebugModeScrambleOnChange  
memDebugModeScrambleOnAll  
memDebugModeFillFree  
memDebugModeAllHeaps  
memDebugModeRecordMinDynHeapFree
```

**Result** Returns 0 if no error, or -1 if an error occurs.

## MemStoreInfo

- Purpose** Return information on either the RAM store or the ROM store for a memory card.
- Declared In** `MemoryMgr.h`
- Prototype** `Err MemStoreInfo (UInt16 cardNo, UInt16 storeNumber, UInt16* versionP, UInt16* flagsP, Char* nameP, UInt32* crDateP, UInt32* bckUpDateP, UInt32* heapListOffsetP, UInt32* initCodeOffset1P, UInt32* initCodeOffset2P, LocalID* databaseDirIDP)`
- Parameters**
- > `cardNo` Card number, either 0 or 1.
  - > `storeNumber` Store number; 0 for ROM, 1 for RAM.
  - <-> `versionP` Pointer to version variable, or 0.
  - <-> `flagsP` Pointer to flags variable, or 0.
  - <-> `nameP` Pointer to character array (32 bytes), or 0.
  - <-> `crDateP` Pointer to creation date variable, or 0.
  - <-> `bckUpDateP` Pointer to backup date variable, or 0.
  - <-> `heapListOffsetP`  
Pointer to `heapListOffset` variable, or 0.
  - <-> `initCodeOffset1P`  
Pointer to `initCodeOffset1` variable, or 0.
  - <-> `initCodeOffset2P`  
Pointer to `initCodeOffset2` variable, or 0.
  - <-> `databaseDirIDP`  
Pointer to database directory chunk ID variable, or 0.
- Result** Returns 0 if no error, or `memErrCardNotPresent`, `memErrRAMOnlyCard`, or `memErrInvalidStoreHeader` if an error occurs.

## Memory Manager

### *Memory Manager Functions*

---

**Comments** Call this routine to retrieve any or all information on either the RAM store or the ROM store for a card. Pass 0 for variables that you don't wish returned.

# Notification Manager

---

This chapter describes the Notification Manager API as declared in the header file `NotifyMgr.h`. It discusses the following topics:

- [Notification Constants](#)
- [Notification Functions](#)
- [Application-Defined Functions](#)

The chapter “[Notifications](#)” in this book lists the possible notifications and describes the data sent with each. Also see the section “[Notifications](#)” on page 30 in the “[Application Startup and Stop](#)” chapter of the *Palm OS Programmer’s Companion*, vol. I for a description of how to use notifications.

## Notification Constants

### Miscellaneous Constants

The following miscellaneous constants are used in the Notification Manager. For other notification constants, see the “[Notifications](#)” chapter in this book.

| Constant                               | Value      | Description                                                                                      |
|----------------------------------------|------------|--------------------------------------------------------------------------------------------------|
| <code>sysNotifyBroadcasterCode</code>  | 'psys'     | The value passed as the creator ID of the broadcaster for notifications broadcast by the system. |
| <code>sysNotifyDefaultQueueSize</code> | 30         | The maximum number of nested broadcasts allowed.                                                 |
| <code>sysNotifyNoDatabaseID</code>     | 0xFFFFFFFF | The database local ID used by the system when it registers for notifications.                    |

## Notification Manager

### Notification Functions

---

| Constant                             | Value | Description                                                                                                                |
|--------------------------------------|-------|----------------------------------------------------------------------------------------------------------------------------|
| <code>sysNotifyNormalPriority</code> | 0     | Typical priority value used when registering for notifications.                                                            |
| <code>sysNotifyVersionNum</code>     | 1     | Current Notification Manager version. This number is stored in the system feature <code>sysFtrNumNotifyMgrVersion</code> . |

---

## Notification Functions

### SysNotifyBroadcast

|                    |                                                                          |                                                                                                                     |
|--------------------|--------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Synchronously send a notification to all applications registered for it. |                                                                                                                     |
| <b>Declared In</b> | <code>NotifyMgr.h</code>                                                 |                                                                                                                     |
| <b>Prototype</b>   | <code>Err SysNotifyBroadcast<br/>(SysNotifyParamType *notify)</code>     |                                                                                                                     |
| <b>Parameters</b>  | <code>&lt;-&gt; notify</code>                                            | Identifies the notification to be broadcast. See <a href="#">SysNotifyParamType</a> .                               |
| <b>Result</b>      | Returns one of the following error codes:                                |                                                                                                                     |
|                    | <code>errNone</code>                                                     | No error.                                                                                                           |
|                    | <code>sysNotifyErrBroadcastBusy</code>                                   | The broadcast stack limit has already been reached.                                                                 |
|                    | <code>sysErrParamErr</code>                                              | The background thread is broadcasting the notification and the <code>notify</code> parameter is <code>NULL</code> . |
|                    | <code>sysNotifyErrNoStackSpace</code>                                    | There is not enough space on the stack for the notification.                                                        |

**Comments** When you call this function, the notification you specify is broadcast to all applications, shared libraries, and other code resources that have registered to receive that notification. The broadcast is performed synchronously, meaning that the system broadcasts the notification immediately and waits for each notification client to perform its notification handler and return before the `SysNotifyBroadcast` call returns. This notification occurs in priority order.

The system allows nested notifications; that is, the recipient of a notification might broadcast a new notification, whose recipient might broadcast another new notification and so on. The constant `sysNotifyDefaultQueueSize` specifies how many levels of nested notification are allowed. If you reach this limit, the error `sysNotifyErrBroadcastBusy` is returned and your notification is not broadcast. To avoid reaching the limit, use [SysNotifyBroadcastDeferred](#) instead of [SysNotifyBroadcast](#) in your notification handlers. This ensures that the notification will not be broadcast until the top of the event loop.

---

**WARNING!** Do not call `SysNotifyBroadcast` from code that might be called from a background task (such as a trap patch) with the memory semaphore reserved. Use `SysNotifyBroadcastDeferred` instead.

---

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## Notification Manager

| <b>Comments</b>       | This function is similar to <a href="#">SysNotifyBroadcast</a> except that the broadcast does not take place until the top of the event loop (specifically, the next time <a href="#">EvtGetEvent</a> is called). The system copies the notify structure to a new memory chunk, which is disposed of upon completion of the broadcast. (The paramSize value is used when copying the notifyDetailsP portion of the notify structure.) |            |                                                                       |                      |                                                                               |                |                                 |                       |                                                      |
| <b>Compatibility</b>  | Implemented only if <a href="#">Notification Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                              |            |                                                                       |                      |                                                                               |                |                                 |                       |                                                      |

## **SysNotifyBroadcastFromInterrupt**

- Purpose** Allows interrupt handlers to enqueue a notification for later broadcast.
- Declared In** `NotifyMgr.h`
- Prototype**

```
Err SysNotifyBroadcastFromInterrupt
(UInt32 notifyType, UInt32 broadcaster,
void *notifyDetailsP)
```
- Parameters**
- > `notifyType` The type of event that occurred. See the chapter [Notifications](#) for a complete list of the notifications that Palm OS® broadcasts.
  - > `broadcaster` The creator ID of the device or application that broadcast the notification.
  - > `notifyDetailsP` Pointer to data specific to this notification. See the [Notifications](#) chapter for the specific instances where this parameter is used.
- Result** Returns one of the following error codes:
- `errNone` No error.
  - `sysNotifyErrQueueFull` The queue has reached its maximum number of entries.
- Comments** Like [SysNotifyBroadcastDeferred](#), this function enqueues a notification to be broadcast at the top of the event loop (specifically, the next time [EvtGetEvent](#) is called). It differs from [SysNotifyBroadcastDeferred](#) in that it is interrupt-safe and intended to be called from interrupt handlers.
- This function is intended to be used by device drivers and other low-level software to generate a notification about a hardware change. For example, the Expansion Manager uses [SysNotifyBroadcastFromInterrupt](#) to broadcast [sysNotifyCardInsertedEvent](#) and

## Notification Manager

### Notification Functions

---

[sysNotifyCardRemovedEvent](#) when a card is inserted into or removed from the expansion slot.  
`SysNotifyBroadcastFromInterrupt` is not intended to be used by general third party applications. Patching `SysNotifyBroadcastFromInterrupt` will cause the system to hang.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## SysNotifyRegister

**Purpose** Register to receive a notification.

**Declared In** `NotifyMgr.h`

**Prototype**  
`Err SysNotifyRegister (UInt16 cardNo,  
LocalID dbID, UInt32 notifyType,  
SysNotifyProcPtr callbackP, Int8 priority,  
void *userDataP)`

**Parameters**

|                            |                                                                                                                                                                                                                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>cardNo</code>     | Number of the storage card on which the application or code resource resides.                                                                                                                                                                                                                                               |
| -> <code>dbID</code>       | Local ID of the application or code resource.                                                                                                                                                                                                                                                                               |
| -> <code>notifyType</code> | The notification that the application wants to receive. See the chapter <a href="#">Notifications</a> .                                                                                                                                                                                                                     |
| -> <code>callbackP</code>  | Set to <code>NULL</code> to receive the notification as an application launch code. If your code does not have a <a href="#">PilotMain</a> function (for example, if it is a shared library), pass a pointer to a function that should be called when the notification is broadcast. See <a href="#">SysNotifyProcPtr</a> . |

- > `priority`      The priority with which the application should receive the event. Most applications and other code resources should always use `sysNotifyNormalPriority`. In rare circumstances, you may need to ensure that your code is notified toward the beginning or toward the end of the notification sequence. If so, be sure to leave some space so that your code won't collide with the system's handling of notifications or with another application's handling of notifications. In general, Palm™ recommends using a value whose least significant bits are 0 (such as 32, 64, 96, and so on). The smaller the priority, the earlier your code is notified.
- > `userDataP`      Caller-defined data to pass to the notification handler.

**Result**      Returns one of the following error codes:

- `errNone`      No error.
- `sysErrParamErr`      The database ID is NULL.
- `sysNotifyErrDuplicateEntry`  
This application is already registered to receive this notification.

**Comments**      Call this function when your code should receive a notification that a specific event has occurred or is about to occur. See the [Notifications](#) chapter for a list of the possible notifications. Once you register for a notification, you remain registered to receive it until a system reset occurs or until you explicitly unregister using [SysNotifyUnregister](#).

If you're writing an application, you should pass NULL as the `callbackP` parameter. In this case, the system notifies your application by sending it the [sysAppLaunchCmdNotify](#) launch code. This launch code's parameter block points to a [SysNotifyParamType](#) structure containing details about the notification.

## Notification Manager

### *Notification Functions*

---

If your code is not in an application, for example, it is a shared library or a separately loaded code resource, then receiving a launch code is not possible. In this case, pass a pointer to a callback function in `callbackP`. This callback should follow the prototype shown in [SysNotifyProcPtr](#). Note that you should always supply a card number and database ID to `SysNotifyRegister`, even if you specify a callback function.

---

**IMPORTANT:** Because the `callbackP` pointer is used to directly call the function, the pointer must remain valid from the time `SysNotifyRegister` is called to the time the notification is broadcast. If the function is in a shared library, you must keep the library open. If the function is in a separately loaded code resource, the resource must remain locked while registered for the notification. When you close a library or unlock a resource, you must first unregister for any notifications. If you don't, the system will crash when the notification is broadcast.

---

Whether the notification handler is responding to `sysAppLaunchCmdNotify` or uses the callback function, the notification handler may perform any processing necessary. As with most launch codes, it's not possible to access global variables. If the handler needs access to any particular value to respond to the notification, pass a pointer to that value in the `userDataP` parameter. The system passes this pointer back to your application or callback function in the launch code's parameter block.

The notification handler may unregister for this notification or register for other notifications. It may also broadcast another notifications; however, it's recommended that you use [SysNotifyBroadcastDeferred](#) to do this so as not to overflow the broadcast stack.

You may display a user interface in your notification handler; however, you should be careful when you do so. Many of the notifications are broadcast during [SysHandleEvent](#), which means your application event loop might not have progressed to the point where it is possible for you to display a user interface, or you might overflow the stack by displaying a user interface at this stage. See

the “[Notifications](#)” chapter to learn which notifications are broadcast during `SysHandleEvent`.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## SysNotifyUnregister

**Purpose** Cancel notification of the given event.

**Declared In** `NotifyMgr.h`

**Prototype** `Err SysNotifyUnregister(UInt16 cardNo,  
LocalID dbID, UInt32 notifyType, Int8 priority)`

**Parameters**

|                            |                                                                               |
|----------------------------|-------------------------------------------------------------------------------|
| -> <code>cardNo</code>     | Number of the storage card on which the application or code resource resides. |
| -> <code>dbID</code>       | Local ID of the application or code resource.                                 |
| -> <code>notifyType</code> | The notification for which to unregister. See <a href="#">Notifications</a> . |
| -> <code>priority</code>   | The priority value you passed as part of <a href="#">SysNotifyRegister</a> .  |

**Result** Returns one of the following error codes:

|                                        |                                                                 |
|----------------------------------------|-----------------------------------------------------------------|
| <code>errNone</code>                   | No error.                                                       |
| <code>sysNotifyErrEntryNotFound</code> | The application wasn't registered to receive this notification. |

**Comments** Use this function to remove your code from the list of those that receive notifications about a particular event. This function is particularly necessary if you are writing a shared library or a separately loaded code resource that receives notifications. When the resource is unloaded, it must unregister for all of its notifications, or the system will crash when the notification is broadcast.

**Compatibility** Implemented only if [Notification Feature Set](#) is present.

## Application-Defined Functions

### **SysNotifyProcPtr**

- Purpose** Handle a notification.
- Declared In** `NotifyMgr.h`
- Prototype** `Err (*SysNotifyProcPtr)  
(SysNotifyParamType *notifyParamsP)`
- Parameters** `-> notifyParamsP`  
Pointer to a structure that contains the notification event that occurred and any other information about it. See [SysNotifyParamType](#).
- Result** Always return 0.
- Comments** You pass this function as a parameter to [SysNotifyRegister](#) when registering code that does not have a [PilotMain](#) for a notification. See the description of [SysNotifyRegister](#) for advice on writing a notification handler.

---

**IMPORTANT:** Because the `callbackP` pointer is used to directly call the function, the pointer must remain valid from the time `SysNotifyRegister` is called to the time the notification is broadcast. If the function is in a shared library, you must keep the library open. If the function is in a separately loaded code resource, the resource must remain locked while registered for the notification. When you close a library or unlock a resource, you must first unregister for any notifications. If you don't, the system will crash when the notification is broadcast.

---

# Overlay Manager

---

This chapter describes the overlay manager API as declared in the header file `OverlayMgr.h`. It discusses the following topics:

- [Overlay Manager Data Structures](#)
- [Overlay Manager Constants](#)
- [Overlay Manager Functions](#)

For more information on the overlay manager, see “[Using Overlays to Localize Resources](#)” on page 365 of the *Palm OS Programmer’s Companion*, vol. I.

## Overlay Manager Data Structures

### OmLocaleType

The `OmLocaleType` struct specifies a locale.

```
typedef struct {
    UInt16    language;
    UInt16    country;
} OmLocaleType;
```

#### Field Descriptions

`language` The language spoken in the locale. This value is one of the `LanguageType` constants.

`country` The country or region where the language is spoken. This value is one of the `CountryType` constants.

**Compatibility** If Palm OS® [4.0 New Feature Set](#) is present, the [LmLocaleType](#) replaces `OmLocaleType`. For backward compatibility, `OmLocaleType` is mapped to `LmLocaleType`.

## Overlay Manager

### Overlay Manager Constants

---

## Overlay Manager Constants

| Constant            | Value  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| omOverlayRscType    | 'ovly' | Symbolic name of an overlay resource that is contained in both the base database and the overlay database.                                                                                                                                                                                                                                                                                                                                                          |
| omOverlayRscID      | 1000   | Resource ID of the overlay resource in both the base database and the overlay database.                                                                                                                                                                                                                                                                                                                                                                             |
| omFtrCreator        | 'ovly' | Creator value used for the omFtrShowErrorsFlag feature.                                                                                                                                                                                                                                                                                                                                                                                                             |
| omFtrDefaultLocale  | 1      | Feature that specifies the default locale stored in the ROM. The default locale is used in cases where the system is attempting to open a “stripped” database (one that requires an overlay) and an overlay matching the current locale cannot be found. In this case, the system then looks for an overlay matching the default locale. Use <a href="#">FtrGet</a> and <a href="#">FtrSet</a> to retrieve and set this value.                                      |
| omFtrShowErrorsFlag | 0      | Feature that controls the number of error messages displayed by the overlay manager. If this feature is set to <code>true</code> , the overlay manager may display several more error messages when validating an overlay against its base database. This feature only takes effect when the error checking level is set to full (common on debug ROMs, not on release ROMs). Use <a href="#">FtrGet</a> and <a href="#">FtrSet</a> to retrieve and set this value. |

---

## Overlay Manager Functions

### OmGetCurrentLocale

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the current locale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Comments</b>      | This function returns the current locale. The current locale controls which overlays are used for resource databases. For example, suppose you have one application and two associated overlays installed, one for US English and one for British English. In this case, if the country specified in the locale returned by this function is <code>cUnitedKingdom</code> , the British English overlay is used for the application. If the country returned is <code>cUnitedStates</code> , the US English overlay is used. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>OmGlueGetCurrentLocale</code> . For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                             |
| <b>See Also</b>      | <a href="#">OmGetSystemLocale</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return a system locale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Declared In</b> | OverlayMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Prototype</b>   | <pre>Err OmGetNextSystemLocale (Boolean iNewSearch,<br/>OmSearchStateType *ioStateInfoP,<br/>LmLocaleType *oLocaleP)</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p>-&gt; iNewSearch     true if this function call is starting a new search, or false if this function call is a continuation of a search.</p> <p>&lt;-&gt; ioStateInfoP     If iNewSearch is false, this must point to the same data used for the previous invocation.</p> <p>&lt;- oLocaleP     The found locale.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Result</b>      | Returns <code>errNone</code> if no error or <code>omErrNoNextSystemLocale</code> if no matches were found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Comments</b>    | <p>You can call this function successively to discover how many system overlays are installed for system resources. Each system overlay found determines a separate valid system locale. Any locale returned by this function can be sent to <a href="#">OmSetSystemLocale</a> to change the system locale.</p> <p>To start the search, pass <code>true</code> for <code>iNewSearch</code>. Allocate an <code>OmSearchStateType</code> structure and pass its address as <code>ioStateInfoP</code>. <code>OmGetNextSystemLocale</code> stores private information in <code>ioStateInfoP</code> and uses it if the search is continued.</p> <p>To continue a search where the previous one left off, pass <code>false</code> for <code>iNewSearch</code> and pass the same <code>ioStateInfoP</code> that you used during the previous call to this function.</p> <p>When called successively, this function eventually returns all system overlays that are in ROM or RAM.</p> |

## Overlay Manager

### Overlay Manager Functions

---

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## OmGetRoutineAddress

**Purpose** Return the address of an overlay manager function.

**Declared In** OverlayMgr.h

**Prototype** void \*OmGetRoutineAddress (OmSelector inSelector)

**Parameters** -> inSelector One of the routine selectors defined in OverlayMgr.h.

**Result** Returns the address of the corresponding function. Returns NULL if an invalid routine selector is passed.

**Comments** You typically use this function to determine whether an overlay manager function exists on the device. As future releases of Palm OS add new functions, older devices with earlier versions of the overlay manager will not implement these newer functions. If OmGetRoutineAddress returns NULL, the function is unavailable.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [IntlGetRoutineAddress](#), [SysGetTrapAddress](#)

## OmGetSystemLocale

|                      |                                                                                                                                                                                                                                                                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the system locale.                                                                                                                                                                                                                                                                                                                     |
| <b>Declared In</b>   | OverlayMgr.h                                                                                                                                                                                                                                                                                                                                  |
| <b>Prototype</b>     | <pre>void OmGetSystemLocale<br/>(LmLocaleType *systemLocale)</pre>                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>    | <- systemLocale Points to an <a href="#">LmLocaleType</a> struct that identifies the system locale.                                                                                                                                                                                                                                           |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                              |
| <b>Comments</b>      | <p>You typically don't use this function. Instead, use <a href="#">OmGetCurrentLocale</a>, which returns the locale that determines which overlays are used.</p> <p>The system locale is saved in the storage heap header and persists across soft resets. When the device is reset, the system locale is used to set the current locale.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">3.5 New Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call OmGlueGetSystemLocale. For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                              |
| <b>See Also</b>      | <a href="#">OmGetCurrentLocale</a>                                                                                                                                                                                                                                                                                                            |

## Overlay Manager

### Overlay Manager Functions

---

## OmLocaleToOverlayDBName

- Purpose** Return the overlay database's name given the base database name and the locale.
- Declared In** OverlayMgr.h
- Prototype**
- ```
Err OmLocaleToOverlayDBName
(const Char *baseDBName,
const LmLocaleType *targetLocale,
Char *overlayDBName)
```
- Parameters**
- > baseDBName The name of the base resource database associated with the overlay.
  - > targetLocale The locale to which this overlay applies. See [LmLocaleType](#). Pass NULL to use the current locale.
  - <- overlayDBName The overlay database name given the base database name and the target locale. This buffer must be at least dmDBNameLength bytes.
- Result** Returns errNone upon success, or omErrUnknownLocale if the targetLocale parameter is invalid.
- Comments** The appropriate overlay database name is currently:
- ```
baseDBName_llCC
```
- where:
- baseDBName* The name of the base database as you passed it in.
  - ll* A two-character code identifying the language.
  - CC* A two-character code identifying the country.
- The base database name is truncated if necessary to allow for this suffix.

For example, the base database “MemoPad” might have an overlay for US English named “MemoPad\_enUS”.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [OmOverlayDBNameToLocale](#)

## **OmOverlayDBNameToLocale**

**Purpose** Return an overlay database’s locale given its name.

**Declared In** OverlayMgr.h

**Prototype**  
`Err OmOverlayDBNameToLocale  
(const Char *overlayDBName,  
LmLocaleType *overlayLocale)`

**Parameters**

- > overlayDBName  
The name of the overlay database.
- <- overlayLocale  
Points to an [LmLocaleType](#) structure identifying the overlay’s locale.

**Result** Returns `errNone` upon success, `omErrBadOverlayDBName` if the string `overlayDBName` is not long enough to have a locale suffix, or `omErrUnknownLocale` if the locale cannot be determined.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

**See Also** [OmLocaleToOverlayDBName](#)

## Overlay Manager

### Overlay Manager Functions

---

## OmSetSystemLocale

- Purpose** Set the system locale and reset the device.
- Declared In** `OverlayMgr.h`
- Prototype**  
`Err OmSetSystemLocale  
(const LmLocaleType *systemLocale)`
- Parameters** `-> systemLocale` An [LmLocaleType](#) structure specifying the locale to switch the system to.
- Result** Returns `errNone` upon success, or one of the following if an error occurs:
- `omErrUnknownLocale`  
There is no system overlay for `systemLocale`.
  - `omErrInvalidLocale`  
The system overlay for `systemLocale` has been found but is invalid.
  - `dmErrInvalidParam`  
An error occurred while opening the overlay.
  - `dmErrMemError` A memory error occurred while opening the overlay.
  - `dmErrDatabaseOpen`  
The system overlay was already open.
- Comments** This function changes the system locale to the specified locale if it exists. It first determines that the system overlay exists for the requested locale and that it matches the base system database. If so, it updates the system locale information saved in the storage heap header and resets the device. After the device is reset, the current locale is set to the system locale.
- A Palm Powered™ device has a default locale hard-coded into the ROM. This locale is used to set the system locale after a hard reset or any time that the storage heap header is invalid. The storage heap header is typically only invalid when the device is turned on for the first time.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present.

In Palm OS 3.5, this function would not switch to a system overlay that was located in the RAM. The Palm OS 4.0 version of this function does return system overlays located in the RAM.

### *Overlay Manager Functions*

---

# Password

---

This chapter provides reference material for the password API. The password API is declared in the header file `Password.h`.

## Password Functions

### PwdExists

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <b>Purpose</b>     | Return <code>true</code> if the system password is set.  |
| <b>Declared In</b> | <code>Password.h</code>                                  |
| <b>Prototype</b>   | <code>Boolean PwdExists ()</code>                        |
| <b>Parameters</b>  | None                                                     |
| <b>Result</b>      | Returns <code>true</code> if the system password is set. |

### PwdRemove

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <b>Purpose</b>     | Remove the encrypted password string and recover data hidden in databases. |
| <b>Declared In</b> | <code>Password.h</code>                                                    |
| <b>Prototype</b>   | <code>void PwdRemove (void)</code>                                         |
| <b>Parameters</b>  | None                                                                       |
| <b>Result</b>      | Returns nothing.                                                           |

## Password

### *Password Functions*

---

#### **PwdSet**

- Purpose** Use a passed string as the new password. The password is stored in an encrypted form.
- Declared In** `Password.h`
- Prototype** `void PwdSet (Char* oldPassword, Char* newPassword)`
- Parameters**
- |                          |                                                                                   |
|--------------------------|-----------------------------------------------------------------------------------|
| <code>oldPassword</code> | The old password must be successfully verified or the new password isn't accepted |
| <code>newPassword</code> | Char* to a string to use as the password. NULL means no password.                 |
- Result** Returns nothing.

#### **PwdVerify**

- Purpose** Verify that the string passed matches the system password.
- Declared In** `Password.h`
- Prototype** `Boolean PwdVerify (Char* string)`
- Parameters**
- |                     |                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>string</code> | String to compare to the system password. NULL means no current password.<br>The allocated length of string must be at least <code>pwdLength</code> characters long. |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
- Result** Returns `true` if the string matches the system password.

# Pen Manager

---

This chapter provides reference material for the pen manager. The pen manager API is declared in the header file `PenMgr.h`.

For more information on the pen manager, see “[The Pen Manager](#)” on page 62 of the *Palm OS Programmer’s Companion*, vol. I.

## Pen Manager Functions

### PenCalibrate

|                           |                                                                                                                                                                                                                                                                                                                                                                                                         |                          |                                            |                           |                                                |                          |                                         |                           |                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------|--------------------------------------------|---------------------------|------------------------------------------------|--------------------------|-----------------------------------------|---------------------------|---------------------------------------------|
| <b>Purpose</b>            | Set the calibration of the pen.                                                                                                                                                                                                                                                                                                                                                                         |                          |                                            |                           |                                                |                          |                                         |                           |                                             |
| <b>Declared In</b>        | <code>PenMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                   |                          |                                            |                           |                                                |                          |                                         |                           |                                             |

## **PenResetCalibration**

- Purpose** Reset the calibration in preparation for calibrating the pen again.
- Declared In** PenMgr.h
- Prototype** Err PenResetCalibration (void)
- Parameters** None.
- Result** Always returns 0.
- Comments** Called by Preferences application before capturing points when calibrating the pen.
- See Also** [PenCalibrate](#)

---

**WARNING!** The digitizer is off after calling this routine and must be calibrated again!

---

# Preferences

---

This chapter describes the preferences API as declared in the header file `Preferences.h`. It discusses the following topics:

- [Preferences Data Types](#)
- [Preferences Constants](#)
- [Preferences Functions](#)

For more information on preferences, see the section “[Preferences](#)” on page 320 of the *Palm OS Programmer’s Companion*, vol. I.

## Preferences Data Types

### MeasurementSystemType

The `MeasurementSystemType` enum specifies the preference for units of measure.

```
typedef enum {
    unitsEnglish = 0,
    unitsMetric
} MeasurementSystemType;
```

#### Value Descriptions

|                           |                                                           |
|---------------------------|-----------------------------------------------------------|
| <code>unitsEnglish</code> | The English measurement system (feet, inches, and so on). |
| <code>unitsMetric</code>  | The Metric system (meters, centimeters, and so on).       |

### SecurityAutoLockType

The `SecurityAutoLockType` enum specifies the values for the auto-locking preference. The auto-locking preference specifies when the device will shut down and lock itself.

## Preferences

### Preferences Data Types

---

```
typedef enum {
    never = 0,
    uponPowerOff,
    atPresetTime,
    afterPresetDelay
} SecurityAutoLockType;
```

#### Value Descriptions

|                  |                                                              |
|------------------|--------------------------------------------------------------|
| never            | The auto-lock feature is disabled.                           |
| uponPowerOff     | The device locks itself each time it is powered off.         |
| atPresetTime     | The device locks itself at a certain time every day.         |
| afterPresetDelay | The device locks itself after a certain amount of idle time. |

## SoundLevelTypeV20

The `SoundLevelTypeV20` enum specifies whether certain sounds are enabled or disabled. This enum is used as the values for several of the system sound preferences.

```
typedef enum {
    slOn = 0,
    slOff = 1
} SoundLevelTypeV20;
```

#### Value Descriptions

|       |          |
|-------|----------|
| slOn  | Enabled  |
| slOff | Disabled |

**Compatibility** This enumerated type is obsolete in Palm OS® versions 3.0 and higher. The preferences that use this enum are replaced by preferences that indicate sound volume as well as whether the sound is on or off.

## SystemPreferencesChoice

The `SystemPreferencesChoice` enum defines values that you can pass to [PrefGetPreference](#) and [PrefSetPreference](#) to retrieve or set a system preference value.

`SystemPreferencesChoice` defines one constant for each field in the `SystemPreferencesType` structure, which should be considered a private structure.

[Table 43.1](#) lists and describes the `SystemPreferencesChoice` constants. For each constant, it shows what type of data is returned by [PrefGetPreference](#) for that constant and which version of the system preferences structure contains this preference.

The system preferences structure keeps track of its own version information because it has been updated several times. Each Palm OS release that updates the system preferences structure increments the structure's version number. [Table 43.1](#) on page 830 specifies which version of the system preferences structure introduced that preference. For each preferences version, there is a constant representing that version. See the section "[Preferences Constants](#)" on page 839 for information on which preferences version corresponds with which Palm OS release. You should check the preference's version number before attempting to obtain the value of any preference introduced after version 2. For example:

```
LmLocaleType currentLocale;
if (PrefGetPreference(prefVersion) >=
    preferenceDataVer9) {
    currentLocale = (LmLocaleType)
        PrefGetPreference(prefLocale);
}
```

Most of the system preferences can be set in the Preferences and Security applications. [Table 43.2](#) on page 838 specifies which system preference is set by each user interface field in these two applications.

## Preferences

### Preferences Data Types

---

**Table 43.1 SystemPreferencesChoice Constants**

| Constant            | Type                             | Version | Description                                                                                                                                                     |
|---------------------|----------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prefVersion         | UInt16                           | 2       | The preferences version number.                                                                                                                                 |
| prefCountry         | <a href="#">CountryType</a>      | 2       | The country for which the device was built.                                                                                                                     |
| prefDateFormat      | <a href="#">DateFormatType</a>   | 2       | The short format used to display dates. For example:<br>95/12/31                                                                                                |
| prefLongDateFormat  | <a href="#">DateFormatType</a>   | 2       | The long format used to display dates. For example:<br>31 Dec 1995                                                                                              |
| prefWeekStartDay    | Int8                             | 2       | The first day of the week (Sunday or Monday). Days of the week are numbered from 0 to 6 starting with Sunday = 0.                                               |
| prefTimeFormat      | <a href="#">TimeFormatType</a>   | 2       | The format used to display time values.                                                                                                                         |
| prefNumberFormat    | <a href="#">NumberFormatType</a> | 2       | The format used for numbers, with regards to the thousands separator and the decimal point.                                                                     |
| prefAutoOffDuration | UInt8                            | 2       | Minutes of user idle time before the device powers off. The default value for this preference is specified by the <code>defaultAutoOffDuration</code> constant. |

**Table 43.1 SystemPreferencesChoice Constants (continued)**

| Constant                       | Type                               | Version | Description                                                                                                                  |
|--------------------------------|------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------|
|                                |                                    |         | prefAutoOffDuration is replaced by prefAutoOffDurationSecs in version 8 of the preferences structure.                        |
| prefSysSoundLevelV20           | <a href="#">SoundLevelType V20</a> | 2       | Specifies whether system sounds are enabled or disabled.                                                                     |
| prefGameSoundLevelV20          | <a href="#">SoundLevelType V20</a> | 2       | Specifies whether game sound effects are on or off.                                                                          |
| prefAlarmSoundLevelV20         | <a href="#">SoundLevelType V20</a> | 2       | Specifies whether sound alarms are on or off.                                                                                |
| prefHidePrivateRecordsV33      | Boolean                            | 2       | If true, applications should not display database records that have the secret attribute bit set.                            |
| prefDeviceLocked               | Boolean                            | 2       | If true, the device is locked. When the device is locked, it remains so until the user enters the password.                  |
| prefLocalSyncRequiresPassword  | Boolean                            | 2       | If true, the user must enter a password before a HotSync <sup>®</sup> operation can be performed.                            |
| prefRemoteSyncRequiresPassword | Boolean                            | 2       | If true, the user must enter a password on the desktop computer before a HotSync operation can be performed.                 |
| prefSysBatteryKind             | Sys Battery Kind                   | 2       | The type of batteries installed. Use <a href="#">SysBatteryInfo</a> to retrieve the battery type instead of this preference. |

## Preferences

### Preferences Data Types

---

**Table 43.1 SystemPreferencesChoice Constants (*continued*)**

| Constant                | Type                                 | Version | Description                                                                                                                                                                       |
|-------------------------|--------------------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prefMinutesWestOfGMT    | UInt32                               | 2       | The time zone given as minutes <b>east</b> of Greenwich Mean Time (GMT). For preferences version 9 and higher, use <code>prefTimeZone</code> instead.                             |
| prefDaylightSavings     | <a href="#">DaylightSavingsTypes</a> | 2       | The type of daylight savings correction. For preferences version 9 and higher, use <code>prefDaylightSavingAdjustment</code> instead.                                             |
| prefRonamaticChar       | UInt16                               | 2       | The virtual character generated when the user enters the ronamatic stroke. The ronamatic stroke is dragging the pen from the Graffiti <sup>®</sup> area to the top of the screen. |
| prefHard1CharAppCreator | UInt32                               | 2       | The creator ID of the application to be launched by the left-most hard key (the Date Book button by default).                                                                     |
| prefHard2CharAppCreator | UInt32                               | 2       | The creator ID of the application to be launched by the second hard key from the left (the Address button by default).                                                            |
| prefHard3CharAppCreator | UInt32                               | 2       | The creator ID of the application to be launched by the second hard key from the right (the To Do List button by default).                                                        |

**Table 43.1 SystemPreferencesChoice Constants (*continued*)**

| Constant                      | Type               | Version | Description                                                                                                   |
|-------------------------------|--------------------|---------|---------------------------------------------------------------------------------------------------------------|
| prefHard4CharAppCreator       | UInt32             | 2       | The creator ID of the application to be launched by the right-most hard key (the Memo Pad button by default). |
| prefCalcCharAppCreator        | UInt32             | 2       | The creator ID of the application to be launched by the Calculator silkscreen button.                         |
| prefHardCradleCharAppCreator  | UInt32             | 2       | The creator ID of the application to be launched by the hard key on the HotSync cradle.                       |
| prefLauncherAppCreator        | UInt32             | 2       | The creator ID of the application to be launched by the Applications silkscreen button.                       |
| prefHardCradle2CharAppCreator | UInt32             | 2       | The creator ID of the application to be launched by the HotSync button on the modem.                          |
| prefAnimationLevel            | AnimationLevelType | 2       | Reserved for future use.                                                                                      |
| prefSysSoundVolume            | UInt16             | 3       | The sound level for system sounds, such as taps and beeps. This is a value from 0 to sndMaxAmp.               |
| prefGameSoundVolume           | UInt16             | 3       | The sound level for game sounds. This is a value from 0 to sndMaxAmp.                                         |

## Preferences

### Preferences Data Types

---

**Table 43.1 SystemPreferencesChoice Constants (continued)**

| Constant                      | Type    | Version | Description                                                                                                                                                                                                                                                                                                      |
|-------------------------------|---------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prefAlarmSoundVolume          | UInt16  | 3       | The sound level for alarms. This is a value from 0 to sndMaxAmp.                                                                                                                                                                                                                                                 |
| prefBeamReceive               | Boolean | 3       | If true, the device can receive beams from other devices. If false, the device cannot receive beams but can still send them.<br><br>This preference is not currently used. Instead, use the <a href="#">ExgControl</a> function with one of the constants described in “ <a href="#">IR Control Constants</a> .” |
| prefCalibrateDigitizerAtReset | Boolean | 3       | If true, the user must recalibrate the digitizer after a soft reset. The default is false.                                                                                                                                                                                                                       |
| prefSystemKeyboardID          | UInt16  | 4       | The resource ID of the keyboard panel.                                                                                                                                                                                                                                                                           |
| prefDefSerialPlugIn           | UInt32  | 4       | The creator ID of the default serial plug-in database.                                                                                                                                                                                                                                                           |
| prefStayOnWhenPluggedIn       | Boolean | 5       | If true, the device stays powered on when it is in the cradle.                                                                                                                                                                                                                                                   |
| prefStayLitWhenPluggedIn      | Boolean | 5       | If true and prefStayOnWhenPluggedIn is true, the device stays lit when it is in its cradle.                                                                                                                                                                                                                      |
| prefAntennaCharAppCreator     | UInt32  | 6       | The creator ID of the application to launch when the antenna is raised (used only for devices with built-in antennas).                                                                                                                                                                                           |

**Table 43.1 SystemPreferencesChoice Constants (*continued*)**

| Constant                     | Type                                  | Version | Description                                                                                                                                                                  |
|------------------------------|---------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prefMeasurementSystem        | <a href="#">MeasurementSystemType</a> | 7       | The system of measurement to use.                                                                                                                                            |
| prefShowPrivateRecords       | <a href="#">privateRecordViewEnum</a> | 8       | Specifies whether the private records should be displayed, masked, or completely hidden.                                                                                     |
| prefAutoOffDurationSecs      | UInt16                                | 8       | Seconds of user idle time before the device powers off. The default value for this preference is specified by the defaultAutoOffDurationSecs constant.                       |
| prefTimeZone                 | Int16                                 | 9       | The time zone given as minutes east of Greenwich Mean Time (GMT).<br><br><b>IMPORTANT:</b> Changing the value of this preference does not update the current time.           |
| prefDaylightSavingAdjustment | Int16                                 | 9       | The number of minutes to add to the current time for daylight savings time.<br><br><b>IMPORTANT:</b> Changing the value of this preference does not update the current time. |
| prefTimeZoneCountry          | <a href="#">CountryType</a>           | 9       | The country selected to specify what the time zone is.                                                                                                                       |

## Preferences

### Preferences Data Types

---

**Table 43.1 SystemPreferencesChoice Constants (*continued*)**

| Constant             | Type                                 | Version | Description                                                                                                                                                                                                                                                                                                                                          |
|----------------------|--------------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| prefAutoLockType     | <a href="#">SecurityAutoLockType</a> | 9       | Specifies when the auto-locking feature should take effect. Possibilities are upon power off, at a preset time, or after a certain number of seconds.                                                                                                                                                                                                |
| prefAutoLockTime     | UInt32                               | 9       | The time value for the auto-locking feature if the system should lock itself after a delay or at a preset time. Depending on the value of <code>prefAutoLockType</code> , this value is either an absolute date and time given as the number of seconds since January 1, 1904 or a timeout value given as a number of seconds from the current time. |
| prefAutoLockTimeFlag | Boolean                              | 9       | If <code>true</code> , <code>prefAutoLockTime</code> is given in minutes. If <code>false</code> , the time is given in hours.                                                                                                                                                                                                                        |
| prefLanguage         | <a href="#">LanguageType</a>         | 9       | The language that the device should use.                                                                                                                                                                                                                                                                                                             |
| prefAttentionFlags   | <a href="#">AttnFlagsType</a>        | 9       | The user's preferences for receiving attention signals. The returned value is a bit mask that should be tested (using the <code>&amp;</code> operator) with one of the following values:                                                                                                                                                             |

**Table 43.1 SystemPreferencesChoice Constants (*continued*)**

| Constant                             | Type                         | Version | Description                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------|------------------------------|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                      |                              |         | kAttnFlagsUserWantsLED<br>kAttnFlagsUserWantsSound<br>kAttnFlagsUserWantsVibrate<br>kAttnFlagsUserWantsCustomEffect<br><br>Note that you can override the values in <code>prefAttentionFlags</code> when you make Attention Manager function calls. See the section <a href="#">“Getting the User’s Attention”</a> on page 283 of the <i>Palm OS Programmer’s Companion</i> , vol. I for more information. |
| <code>prefDefaultAppCreator</code>   | <code>UInt32</code>          | 9       | Creator ID of the application that is launched after a reset. If 0, the system default application is launched.                                                                                                                                                                                                                                                                                            |
| <code>prefLocale</code>              | <a href="#">LmLocaleType</a> | 9       | The device’s current locale, which specifies the country and language.                                                                                                                                                                                                                                                                                                                                     |
| <code>prefDefFepPlugInCreator</code> | <code>UInt32</code>          | 10      | Creator ID of the default FEP plug-in.                                                                                                                                                                                                                                                                                                                                                                     |
| <code>prefColorThemeID</code>        | <a href="#">DmResID</a>      | 10      | Resource ID of the color theme.                                                                                                                                                                                                                                                                                                                                                                            |

**Preferences in the User Interface**

[Table 43.2](#) shows the `SystemPreferencesChoice` constants and how they correspond to the values that users can set in the Preferences and Security applications. For further information about each preference, see [Table 43.1](#).

## Preferences

### Preferences Data Types

1. The Alarm Vibrate and Alarm LED preferences only appear on handhelds running Palm OS 4.0 and later that have the appropriate hardware capabilities. If you install Palm OS 4.0 on an older device, these preferences do not display.

## Preferences Constants

The following table describes the constants defined in the Preferences.h header file.

## Preferences

### *Preferences Constants*

---

| <b>Constant</b>                         | <b>Value</b> | <b>Description</b>                                                                                                                                                 |
|-----------------------------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>defaultAutoLockTime</code>        | 0            | Initial setting for the <code>prefAutoLockTime</code> preference.                                                                                                  |
| <code>defaultAutoLockTimeFlag</code>    | 0            | Initial setting for the <code>prefAutoLockTimeFlag</code> preference.                                                                                              |
| <code>defaultAutoLockType</code>        | never        | Initial setting for the <code>prefAutoLockType</code> preference.                                                                                                  |
| <code>defaultAutoOffDuration</code>     | 2            | Initial setting for the <code>prefAutoOffDuration</code> preference, given in minutes.                                                                             |
| <code>defaultAutoOffDurationSecs</code> | 120          | Initial setting for the <code>prefAutoOffDurationSecs</code> preference, given in seconds. The value is 2 times the number of seconds in a minute, or 120 seconds. |
| <code>defaultAlarmSoundLevel</code>     | s1On         | Initial setting for the <code>prefAlarmSoundLevelV20</code> preference.                                                                                            |
| <code>defaultAlarmSoundVolume</code>    | sndMaxAmp    | Initial setting for the <code>prefAlarmSoundVolume</code> preference.                                                                                              |
| <code>defaultGameSoundLevel</code>      | s1On         | Initial setting for the <code>prefGameSoundLevelV20</code> preference.                                                                                             |
| <code>defaultGameSoundVolume</code>     | sndMaxAmp    | Initial setting for the <code>prefGameSoundVolume</code> preference.                                                                                               |
| <code>defaultSysSoundLevel</code>       | s1On         | Initial setting for the <code>prefSysSoundLevelV20</code> preference.                                                                                              |
| <code>defaultSysSoundVolume</code>      | sndMaxAmp    | Initial setting for the <code>prefSysSoundVolume</code> preference.                                                                                                |

| <b>Constant</b>         | <b>Value</b>        | <b>Description</b>                                                                                           |
|-------------------------|---------------------|--------------------------------------------------------------------------------------------------------------|
| noPreferenceFound       | -1                  | The value that <a href="#">PrefGetAppPreferences</a> returns to indicate that preferences couldn't be found. |
| preferenceDataVer2      | 2                   | Version 2 of the system preferences structure, used for Palm OS 2.0.                                         |
| preferenceDataVer3      | 3                   | Version 3 of the system preferences structure, used for Palm OS 3.0.                                         |
| preferenceDataVer4      | 4                   | Version 4 of the system preferences structure, used for Palm OS 3.1.                                         |
| preferenceDataVer5      | 5                   | Version 5 of the system preferences structure, used for Palm OS 3.2.                                         |
| preferenceDataVer6      | 6                   | Version 6 of the system preferences structure, used for Palm OS 3.3.                                         |
| preferenceDataVer8      | 8                   | Version 8 of the system preferences structure, used for Palm OS 3.5.                                         |
| preferenceDataVer9      | 9                   | Version 9 of the system preferences structure, used for Palm OS 4.0.                                         |
| preferenceDataVer10     | 10                  | Version 10 of the system preferences structure, used for Palm OS 5.0.                                        |
| preferenceDataVer11     | 11                  | Version 11 of the system preferences structure, used for Palm OS 5.1.                                        |
| preferenceDataVerLatest | preferenceDataVer11 | The latest version of the system preferences structure.                                                      |

The IDs 0x8000 through 0xFFFF are reserved for system use.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |            |                                                          |       |                                                                                                               |          |                                              |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <- prefs           | Pointer to a buffer to hold the preferences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |            |                                                          |       |                                                                                                               |          |                                              |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <-> prefsSize      | Pointer to the size of the <code>prefs</code> buffer passed in. Upon return, contains the number of bytes actually written or the number of bytes needed for the <code>prefs</code> structure.<br><br>To determine the required size for the <code>prefs</code> structure, set <code>prefsSize</code> to 0 and pass <code>NULL</code> for <code>prefs</code> . Upon return, the <code>prefsSize</code> parameter contains the required size. Never set <code>prefs</code> to <code>NULL</code> without also setting <code>prefsSize</code> to 0.<br><br>Always compare the value returned in this parameter with the value you passed in. If the two values differ, you need to resize the <code>prefs</code> structure and call this function again.                                                                                                                                                                                                                                                                                                                                                                                                   |            |                                                          |       |                                                                                                               |          |                                              |               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

-> saved

If `true`, retrieve the preferences from the “saved” preferences database, which is backed up during a HotSync operation. If `false`, retrieve the preferences from the “unsaved” preferences database, which is usually not backed up during a HotSync operation.

**Result** Returns the version number of the retrieved preferences resource, or returns the constant `noPreferenceFound` if the preferences resource wasn’t found. The returned version number is the same version number that was passed to the [PrefSetAppPreferences](#) function.

**Comments** Use this function to retrieve the preferences that you previously set with the [PrefSetAppPreferences](#) function. You typically call this function in your `StartApplication` function upon a normal launch. The values of the `id` and `saved` parameters should be the same as you specified when calling [PrefSetAppPreferences](#), and the `prefs` parameter should be a structure of the same type as you passed to [PrefSetAppPreferences](#). Most applications store all preferences in a single preferences resource retrieved by a single call to `PrefGetAppPreferences`, but this is not required. You can use multiple preferences resources if you wish.

Applications typically call `PrefGetAppPreferences` twice: once with `prefs` set to `NULL` and `prefsSize` set to `0` to determine how much memory to allocate for the preferences structure, and a second time after allocating the required amount of memory to obtain a copy of the application’s preferences resource.

The version number returned by this function allows you to handle the case where a new version of the application is being run for the first time. You can compare the value returned by this function with the current version number to determine if you need to set default values for any preferences created by the current release. For more information, see the section “[Updating Preferences Upon a New Release](#)” on page 329 of the *Palm OS Programmer’s Companion*, vol. I.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [PrefSetPreferences](#), [PrefGetAppPreferencesV10](#)

## **PrefGetAppPreferencesV10**

- Purpose** Return a copy of an application's preferences.
- Declared In** `Preferences.h`
- Prototype** `Boolean PrefGetAppPreferencesV10 (UInt32 type, UInt16 version, void *prefs, UInt16 prefsSize)`
- Parameters**
- > `type` Creator ID of the application that owns the preferences.
  - > `version` Version number of the application's preferences.
  - <- `prefs` Pointer to a buffer to hold preferences.
  - > `prefsSize` Size of the buffer passed.
- Result** Returns `false` if the preference resource was not found or the preference resource contains the wrong version number.
- Comments** The content and format of an application preference is application-dependent.
- Compatibility** This function corresponds to the 1.0 version of `PrefGetAppPreferences`.
- See Also** [PrefSetPreferences](#), [PrefGetAppPreferences](#)

## PrefGetPreference

|                      |                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return a system preference. Use this function instead of <a href="#">PrefGetPreferences</a> .                                                                                                                                                  |
| <b>Declared In</b>   | <code>Preferences.h</code>                                                                                                                                                                                                                     |
| <b>Prototype</b>     | <code>UInt32 PrefGetPreference<br/>(SystemPreferencesChoice choice)</code>                                                                                                                                                                     |
| <b>Parameters</b>    | <code>-&gt; choice</code> A constant that specifies what preference to retrieve. See <a href="#">SystemPreferencesChoice</a> .                                                                                                                 |
| <b>Result</b>        | Returns the system preference or 0 if the preference could not be found. On debug ROMs, a non-fatal error message is also displayed if the specified preference cannot be found.                                                               |
| <b>Comments</b>      | This function replaces the 1.0 function <a href="#">PrefGetPreferences</a> . While <code>PrefGetPreferences</code> only lets you retrieve the whole system preferences structure, this function lets you specify which preference to retrieve. |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                                                                                                                            |
| <b>See Also</b>      | <a href="#">PrefSetPreference</a> , <a href="#">PrefGetAppPreferences</a> ,<br><a href="#">PrefGetAppPreferencesV10</a>                                                                                                                        |

## PrefGetPreferences

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Purpose</b>     | Return a copy of the system preferences.                           |
| <b>Declared In</b> | <code>Preferences.h</code>                                         |
| <b>Prototype</b>   | <code>void PrefGetPreferences (SystemPreferencesPtr p)</code>      |
| <b>Parameters</b>  | <code>&lt;- p</code> Pointer to system preferences.                |
| <b>Result</b>      | Returns nothing. Stores the system preferences in <code>p</code> . |

## Preferences

### Preferences Functions

---

**Comments** The `p` parameter points to a memory block allocated by the caller that is filled in by this function.

This function is often called in `StartApplication` to get localized settings.

---

**NOTE:** This function can only be used to retrieve preferences that were in the 1.0 version of the preferences structure.

---

**See Also** [PrefSetPreferences](#)

## PrefOpenPreferenceDB

**Purpose** Return a handle to either the saved or unsaved preference database.

**Declared In** `Preferences.h`

**Prototype** `DmOpenRef PrefOpenPreferenceDB (Boolean saved)`

**Parameters** `-> saved` If `true`, open the “saved” preferences database, which is backed up during a `HotSync` operation. If `false`, open the “unsaved” preferences database, which usually is not backed up during a `HotSync` operation.

**Result** Returns the handle, or 0 if an error results.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [PrefGetPreference](#), [PrefSetPreference](#), [PrefOpenPreferenceDBV10](#)

## PrefOpenPreferenceDBV10

- Purpose** Return a handle to the system preference database.
- Declared In** `Preferences.h`
- Prototype** `DmOpenRef PrefOpenPreferenceDBV10 (void)`
- Parameters** None.
- Result** Returns the handle, or 0 if an error results.
- Compatibility** This function corresponds to the 1.0 version of `PrefOpenPreferenceDB`.
- See Also** [PrefGetPreferences](#), [PrefSetPreferences](#)

## PrefSetAppPreferences

- Purpose** Set an application's preferences in the specified preferences database.
- Declared In** `Preferences.h`
- Prototype** `void PrefSetAppPreferences (UInt32 creator, UInt16 id, Int16 version, const void *prefs, UInt16 prefsSize, Boolean saved)`
- Parameters**
- |            |                                                                                                                                              |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| -> creator | Creator ID of the application that owns this preference.                                                                                     |
| -> id      | ID number of the preference to set. An application can have multiple preferences. The IDs 0x8000 through 0xFFFF are reserved for system use. |
| -> version | Version number of the application's preferences.                                                                                             |

## Preferences

### Preferences Functions

---

|              |                                                                                                                                          |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------|
| -> prefs     | Pointer to a buffer that holds the current value of the preferences structure. Pass NULL if you want to delete the preferences.          |
| -> prefsSize | Size of the buffer passed. Pass 0 if you want to delete the preferences structure.                                                       |
| -> saved     | If true, saves the preferences in the "saved" preferences database. If not, saves the preferences in the "unsaved" preferences database. |

**Result** Returns nothing.

**Comments** You typically call this function in your `StopApplication` function to save the current state of the application or if the user has changed an application preference during the current session.

The "saved" preferences database is backed up when a user performs the `HotSync` operation. The "unsaved" preferences database is not backed up by default. (The user can use a third-party tool to set the backup bit in the "unsaved" preferences database, which would cause it to be backed up.) Both the "saved" and the "unsaved" preferences reside in the storage heap and thus persist across soft resets. The only way that preferences are lost is if a hard reset is performed. "[Which Preferences Database to Use](#)" on page 327 of the *Palm OS Programmer's Companion*, vol. I describes how to choose between the "saved" and "unsaved" preferences databases.

The version number that you pass as the `version` parameter is returned when the preferences are retrieved by [PrefGetAppPreferences](#). You can use this version number to determine if a new release of the application is being run for the first time. For more information, see the section "[Updating Preferences Upon a New Release](#)" on page 329 of the *Palm OS Programmer's Companion*, vol. I.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [PrefSetAppPreferencesV10](#)

## **PrefSetAppPreferencesV10**

|                      |                                                                                                                                                                                                                                                                                                                                             |            |                                                          |            |                                    |          |                                          |              |                            |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|----------------------------------------------------------|------------|------------------------------------|----------|------------------------------------------|--------------|----------------------------|
| <b>Purpose</b>       | Save an application's preferences in the preferences database.                                                                                                                                                                                                                                                                              |            |                                                          |            |                                    |          |                                          |              |                            |
| <b>Declared In</b>   | <code>Preferences.h</code>                                                                                                                                                                                                                                                                                                                  |            |                                                          |            |                                    |          |                                          |              |                            |
| <b>Prototype</b>     | <code>void PrefSetAppPreferencesV10 (UInt32 creator, Int16 version, void *prefs, UInt16 prefsSize)</code>                                                                                                                                                                                                                                   |            |                                                          |            |                                    |          |                                          |              |                            |

| -> creator           | Creator ID of the application that owns this preference.                                                                                                                                                                                                                                                                                    |            |                                                          |            |                                    |          |                                          |              |                            |
| -> version           | Version number of the application.                                                                                                                                                                                                                                                                                                          |            |                                                          |            |                                    |          |                                          |              |                            |
| -> prefs             | Pointer to a buffer holding preferences.                                                                                                                                                                                                                                                                                                    |            |                                                          |            |                                    |          |                                          |              |                            |
| -> prefsSize         | Size of the buffer passed.                                                                                                                                                                                                                                                                                                                  |            |                                                          |            |                                    |          |                                          |              |                            |
| <b>Result</b>        | Returns nothing.                                                                                                                                                                                                                                                                                                                            |            |                                                          |            |                                    |          |                                          |              |                            |
| <b>Comments</b>      | The content and format of an application preference is application-dependent.                                                                                                                                                                                                                                                               |            |                                                          |            |                                    |          |                                          |              |                            |
| <b>Compatibility</b> | This function corresponds to the 1.0 version of <code>PrefSetAppPreferences</code> .                                                                                                                                                                                                                                                        |            |                                                          |            |                                    |          |                                          |              |                            |
| <b>See Also</b>      | <a href="#">PrefSetAppPreferences</a> , <a href="#">PrefGetPreferences</a>                                                                                                                                                                                                                                                                  |            |                                                          |            |                                    |          |                                          |              |                            |

## Preferences

### Preferences Functions

---

#### PrefSetPreference

- Purpose** Set a system preference. Using this function instead of `PrefSetPreferences` allows you to set selected preferences without having to access the whole structure.
- Declared In** `Preferences.h`
- Prototype**  
`void PrefSetPreference  
(SystemPreferencesChoice choice, UInt32 value)`
- Parameters**
- > choice      A [SystemPreferencesChoice](#) constant specifying the preference to be set.
  - > value      Value to assign to the preference.
- Result** Returns nothing. If the specified preference cannot be found, displays a non-fatal error message on debug ROMs. On release ROMs, this function fails silently.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

#### PrefSetPreferences

- Purpose** Set the system preferences.
- Declared In** `Preferences.h`
- Prototype**  
`void PrefSetPreferences (SystemPreferencesPtr p)`
- Parameters**
- > p      Pointer to system preferences.
- Result** Returns nothing.
- Comments** Unless there's a reason for you to access the whole preferences structure, call [PrefSetPreference](#) instead.

---

**NOTE:** This function can only be used to set preferences that were in the 1.0 version of the preferences structure.

---

**See Also** [PrefGetPreferences](#)

# Rectangles

---

This chapter provides reference material for the rectangles API, declared in the header file `Rect.h`. It is divided into the following sections:

- [Rectangle Data Structures](#)
- [Rectangle Functions](#)

## Rectangle Data Structures

### PointType

The `PointType` structure defines a point within a window or on the screen.

```
typedef struct PointType {
    Coord x;
    Coord y;
} PointType;
```

### Field Descriptions

|   |                        |
|---|------------------------|
| x | Horizontal coordinate. |
| y | Vertical coordinate.   |

### RectangleType

The `RectangleType` structure defines a rectangular portion of a window or of the screen.

```
typedef struct RectangleType {
    PointType topLeft;
    PointType extent;
} RectangleType;
typedef RectangleType *RectanglePtr;
```

**Field Descriptions**

|                      |                                                                                                                        |
|----------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>topLeft</code> | Coordinates of the upper-left corner of the rectangle relative to the window or screen in which the rectangle resides. |
| <code>extent</code>  | Width ( <code>extent.x</code> ) and height ( <code>extent.y</code> ) of the rectangle.                                 |

## Rectangle Functions

### **RctCopyRectangle**

|                    |                                                                                                   |                                          |
|--------------------|---------------------------------------------------------------------------------------------------|------------------------------------------|
| <b>Purpose</b>     | Copy the source rectangle to the destination rectangle.                                           |                                          |
| <b>Declared In</b> | <code>Rect.h</code>                                                                               |                                          |
| <b>Prototype</b>   | <pre>void RctCopyRectangle<br/>(const RectangleType* srcRectP,<br/>RectangleType* dstRectP)</pre> |                                          |
| <b>Parameters</b>  | <code>srcRectP</code>                                                                             | A pointer to the rectangle to be copied. |
|                    | <code>dstRectP</code>                                                                             | A pointer to the destination rectangle.  |
| <b>See Also</b>    | <a href="#">RctSetRectangle</a>                                                                   |                                          |

### **RctGetIntersection**

|                    |                                                                                                                     |                                  |
|--------------------|---------------------------------------------------------------------------------------------------------------------|----------------------------------|
| <b>Purpose</b>     | Determine the intersection of two rectangles.                                                                       |                                  |
| <b>Declared In</b> | <code>Rect.h</code>                                                                                                 |                                  |
| <b>Prototype</b>   | <pre>void RctGetIntersection<br/>(const RectangleType* r1P,<br/>const RectangleType* r2P, RectangleType* r3P)</pre> |                                  |
| <b>Parameters</b>  | <code>r1P</code>                                                                                                    | A pointer to a source rectangle. |

`r2P` A pointer to the other source rectangle.

`r3P` Upon return, points to a rectangle representing the intersection of `r1` and `r2`.

**Comments** The rectangle type [RectangleType](#), which is pointed to by `RectanglePtr`, stores the coordinates for the top-left corner of the rectangle plus the rectangle's width and height. This function returns in the `r3` parameter a pointer to the rectangle that represents the intersection of the first two rectangles.

If the rectangles `r1` and `r2` do not intersect, `r3` contains a rectangle whose top-left coordinate is the maximum of `r1` and `r2`'s top-left coordinates and whose extent varies based on the location of the two rectangles.

**Compatibility** On releases prior to Palm OS® 3.5, if rectangles `r1` and `r2` don't intersect, `r3` contains a rectangle that begins at coordinates (0,0 and has 0 width and 0 height. On Palm OS 3.5 and later, if the two rectangles don't intersect then `r3` contains a rectangle in which one or both of the extent coordinates is zero.

## RctInsetRectangle

**Purpose** Move all of the boundaries of a rectangle by a specified offset.

**Declared In** `Rect.h`

**Prototype** `void RctInsetRectangle (RectangleType* rP,  
Coord insetAmt)`

**Parameters** `rP` A pointer to the rectangle.

`insetAmt` Number of pixels to move the boundaries. This can be a negative number.

**Comments** The rectangle type [RectangleType](#), which is pointed to by `RectanglePtr`, stores the coordinates for the top-left corner of the rectangle plus the rectangle's width and height. This function adds `insetAmt` to the x and y values of the top-left coordinate and then

adjusts the width and the height accordingly so that all of the sides of the rectangle are contracted or expanded by the same amount.

A positive `insetAmt` creates a smaller rectangle that is contained inside the old rectangle's boundaries. A negative `insetAmt` creates a larger rectangle that surrounds the old rectangle.

**See Also** [RctOffsetRectangle](#)

### RctOffsetRectangle

**Purpose** Move the top and left boundaries of a rectangle by the specified values.

**Declared In** `Rect.h`

**Prototype** `void RctOffsetRectangle (RectangleType* rP, Coord deltaX, Coord deltaY)`

**Parameters**

|                     |                                                                            |
|---------------------|----------------------------------------------------------------------------|
| <code>rP</code>     | A pointer to the rectangle.                                                |
| <code>deltaX</code> | Number of pixels to move the left boundary. This can be a negative number. |
| <code>deltaY</code> | Number of pixels to move the top boundary. This can be a negative number.  |

**Comments** The rectangle type [RectangleType](#), which is pointed to by `RectanglePtr`, stores the coordinates for the top-left corner of the rectangle plus the rectangle's width and height. This function adds `deltaX` to the x value of the top-left coordinate and `deltaY` to the y value. The width and height are unchanged. Thus, this function shifts the position of the rectangle by the `deltaX` and `deltaY` amounts.

**See Also** [RctInsetRectangle](#)

## RctPtInRectangle

|                    |                                                                                                                                                                                                                       |                |                                |                |                                |                 |                |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|--------------------------------|----------------|--------------------------------|-----------------|----------------|
| <b>Purpose</b>     | Determine if a point lies within a rectangle's boundaries.                                                                                                                                                            |                |                                |                |                                |                 |                |
| <b>Declared In</b> | <code>Rect.h</code>                                                                                                                                                                                                   |                |                                |                |                                |                 |                |
| <b>Prototype</b>   | <code>Boolean RctPtInRectangle (Coord x, Coord y, const RectangleType* rP)</code>                                                                                                                                     |                |                                |                |                                |                 |                |
| <b>Parameters</b>  | <table><tr><td><code>x</code></td><td>The x coordinate of the point.</td></tr><tr><td><code>y</code></td><td>The y coordinate of the point.</td></tr><tr><td><code>rP</code></td><td>The rectangle.</td></tr></table> | <code>x</code> | The x coordinate of the point. | <code>y</code> | The y coordinate of the point. | <code>rP</code> | The rectangle. |
| <code>x</code>     | The x coordinate of the point.                                                                                                                                                                                        |                |                                |                |                                |                 |                |
| <code>y</code>     | The y coordinate of the point.                                                                                                                                                                                        |                |                                |                |                                |                 |                |
| <code>rP</code>    | The rectangle.                                                                                                                                                                                                        |                |                                |                |                                |                 |                |
| <b>Result</b>      | Returns <code>true</code> if the point ( <code>x</code> , <code>y</code> ) lies within the boundaries of rectangle <code>r</code> , <code>false</code> otherwise.                                                     |                |                                |                |                                |                 |                |

| <code>left</code>   | The x value for the top-left coordinate of the rectangle.                                                                                                                                                                                                                                                                                                                                                                                       |                 |                                       |                   |                                                           |                  |                                                           |                    |                        |                     |                         |
| <code>top</code>    | The y value for the top-left coordinate of the rectangle.                                                                                                                                                                                                                                                                                                                                                                                       |                 |                                       |                   |                                                           |                  |                                                           |                    |                        |                     |                         |
| <code>width</code>  | The rectangle's width.                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |                                       |                   |                                                           |                  |                                                           |                    |                        |                     |                         |
| <code>height</code> | The rectangle's height.                                                                                                                                                                                                                                                                                                                                                                                                                         |                 |                                       |                   |                                                           |                  |                                                           |                    |                        |                     |                         |
| <b>See Also</b>     | <a href="#">RctCopyRectangle</a>                                                                                                                                                                                                                                                                                                                                                                                                                |                 |                                       |                   |                                                           |                  |                                                           |                    |                        |                     |                         |

# Sound Manager

---

This chapter describes the API that's defined by the Sound Manager. You use this API to make and record sounds.

The Sound Manager controls two independent sound facilities:

- Single voice, monophonic, square-wave sound synthesis, useful for system beeps. This is the traditional (pre-OS 5) PalmSource sound; let's call it "simple sound."
- Stereo, multi-format, sampled data recording and playback (new in Palm OS 5). We'll call it "sampled sound."

The API for these two facilities are entirely separate; the simple sound API is described first...

- [Simple Sound Structures and Constants](#)
- [Simple Sound Functions](#)
- [Simple Sound Application-Defined Functions](#)

...followed by the sampled sound API.

- [Sampled Sound Structures, Constants, and Data Types](#)
- [Sampled Sound Functions](#)
- [Sampled Sound Application-Defined Functions](#)

All elements described here are declared in `SoundMgr.h`.

## Overview

There are three ways to play a simple sound:

- You can play a single tone of a given pitch, amplitude, and duration by calling [SndDoCmd](#).
- You can play a pre-defined system sound through [SndPlaySystemSound](#).
- You can play a tune by passing in a Level 0 Standard MIDI file (SMF) through the [SndPlaySmf](#) function.

## Sound Manager

### *Simple Sound Structures and Constants*

---

There are a handful of other simple sound functions, but they mostly support these three fundamental functions.

Over in the sampled sound facilities, there are two fundamental functions:

- [SndStreamCreate](#) opens a new sampled sound “stream” from/into which you record/playback buffers of “raw” data. The trick is that you first have to configure the stream to tell it how to interpret the data.
- [SndPlayResource](#) is used to playback sound data that’s read from a (formatted) sound file. The function configures the playback stream for you, based on the format information in the sound file header. Currently, only uncompressed WAV and IMA ADPCM WAV formats are recognized (this also known as DVI ADPCM). Note that `SndPlayResource` is *only* used to play back sound; it can’t be used for recording.

The Sound Manager also provides functions that let you set the volume and stereo panning for individual recording and playback streams. See [SndStreamSetVolume](#) and [SndStreamSetPan](#).

For more information on the Sound Manager, see the section “[Sound](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Simple Sound Structures and Constants

### **SndCallbackInfoType**

Structure that encapsulates a callback function and its argument data. `SndCallbackInfoType` is used by the [SndSmfCallbacksType](#) structure, which is used to list the callback functions that are called during SMF playback.

```
typedef struct SndCallbackInfoType {
    MemPtr    funcP;
    UInt32    dwUserData;
} SndCallbackInfoType;
```

The fields are:

---

|            |                                                    |
|------------|----------------------------------------------------|
| funcP      | A pointer to the callback function.                |
| dwUserData | Data that's passed as an argument to the function. |

---

## SndCmdIDTag

The `SndCmdIDTag` enumeration contains constants that represent specific sound operations used in simple sound playback.

```
typedef enum SndCmdIDTag {
    sndCmdFreqDurationAmp = 1,
    sndCmdNoteOn,
    sndCmdFrqOn,
    sndCmdQuiet
};
```

See [SndDoCmd](#) for descriptions of the operations that are represented by these values.

## SndCommandType

The `SndCommandType` structure encapsulates a sound synthesis operation and its associated parameters. Used by the [SndDoCmd](#) function.

```
typedef struct SndCommandType {
    SndCmdIDType cmd;
    UInt8 reserved;
    Int32 param1;
    UInt16 param2;
    UInt16 param3;
} SndCommandType;
```

## Sound Manager

### Simple Sound Structures and Constants

---

The fields are:

---

|                        |                                                                                                                   |
|------------------------|-------------------------------------------------------------------------------------------------------------------|
| cmd                    | Constant that represents a sound operation. The operations are listed and described in <a href="#">SndDoCmd</a> . |
| reserved               | Don't touch this one.                                                                                             |
| param1, param2, param3 | Operation-specific parameters. The parameters' meanings are described in <a href="#">SndDoCmd</a> .               |

---

### sndMaxAmp

Constant that defines the upper limit for simple sound amplitude values. Use this value with the simple sound API only (such as [SndDoCmd](#)). The `sndMaxAmp` value is *not* compatible with the sampled sound amplitude range.

```
#define sndMaxAmp 64
```

### SndMidiListItemType

Structure that locates a MIDI file. The structure is used by the [SndCreateMidiList](#) function.

```
typedef struct SndMidiListItemType{
    Char  name[sndMidiNameLength];
    UInt32  uniqueRecID;
    MemHandle dbH;
} SndMidiListItemType;
```

The fields are:

---

|             |                                                |
|-------------|------------------------------------------------|
| name        | The null-terminated name of the MIDI file.     |
| uniqueRecID | The ID of the record that holds the MIDI file. |
| dbH         | Handle to the database that holds the record.  |

---

## sndMidiNameLength

Constant that defines the maximum string length (including the null terminator) for a MIDI file or MIDI track name.

```
#define sndMidiNameLength 32
```

## SndMidiRecHdrType

Structure that encapsulates the header of a MIDI record.

```
typedef struct SndMidiRecHdrType {  
    UInt32  signature;  
    UInt8   bDataOffset;  
    UInt8   reserved;  
} SndMidiRecHdrType;
```

The fields are:

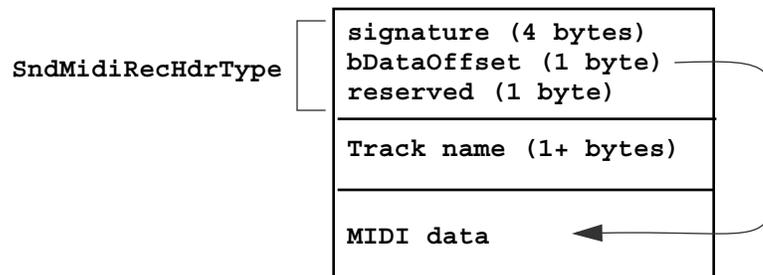

---

|             |                                                                                        |
|-------------|----------------------------------------------------------------------------------------|
| signature   | Always set to <a href="#">sndMidiRecSignature</a> .                                    |
| bDataOffset | Offset, in bytes, from the beginning of the record to the first byte of the MIDI data. |
| reserved    | Always set to 0.                                                                       |

---

[Figure 45.1](#) depicts a complete Palm OS® MIDI record.

**Figure 45.1 Palm OS Midi Record**

To get to the track name, you have to bump the structure pointer yourself. For example:

## Sound Manager

### Simple Sound Structures and Constants

---

---

```
Char *trackName = (Char *)myMidiRecHdr + sizeof(SndMidiRecHdrType);
```

---

The MIDI track name is null-terminated, even if it's empty. It's at least one byte long and at most [sndMidiNameLength](#) bytes long.

### sndMidiRecSignature

Endian-cognizant constant that's used to tag a MIDI record. The constant is used as the value of the signature field of the [SndMidiRecHdrType](#) structure.

```
#if CPU_ENDIAN == CPU_ENDIAN_BIG
#define sndMidiRecSignature 'PMrc'
#else
#define sndMidiRecSignature 'crMP'
```

### SndSmfCallbacksType

Structure that contains a set of application-defined functions that are called during MIDI playback. To register your callback functions, call [SndPlaySmf](#).

```
typedef struct SndSmfCallbacksType {
    SndCallbackInfoType completion;
    SndCallbackInfoType blocking;
    SndCallbackInfoType reserved;
} SndSmfCallbacksType;
```

The fields are:

---

|            |                                                              |
|------------|--------------------------------------------------------------|
| completion | Completion function; see <a href="#">SndComplFuncType</a> .  |
| blocking   | Blocking function; see <a href="#">SndBlockingFuncType</a> . |
| reserved   | Reserved. Set this field to 0.                               |

---

## SndSmfChanRangeType

Structure that defines the range of enabled MIDI channels. Events on MIDI channels outside the enabled range are ignored. By default, no channels are enabled.

```
typedef struct SndSmfChanRangeType {
    UInt8  bFirstChan;
    UInt8  bLastChan;
} SndSmfChanRangeType;
```

The fields are:

---

|            |                                                 |
|------------|-------------------------------------------------|
| bFirstChan | The first enabled channel in the range [0, 15]. |
| bLastChan  | The last enabled channel in the range [0, 15].  |

---

---

**WARNING!** The `SndSmfChanRangeType` structure expects MIDI channels to be in the range [0, 15]; real MIDI channel values are in the range [1, 16]. Thus, PalmSource MIDI channel 0 is real MIDI channel 1, PalmSource MIDI channel 1 is real MIDI channel 2, and so on.

---

## SndSmfCmdEnum

Constants used to tell [SndPlaySmf](#) whether to set or retrieve data.

```
typedef enum SndSmfCmdEnumTag {
    sndSmfCmdPlay = 1,
    sndSmfCmdDuration,
} SndSmfCmdEnum;
```

See [SndPlaySmf](#) for descriptions of these values.

## SndSmfOptionsType

Structure that establishes MIDI performance parameters. This structure is used in the [SndPlaySmf](#) function to establish new parameter settings or to return the currently set values, depending

## Sound Manager

### Simple Sound Structures and Constants

---

on how the function is called. In the case where the structure returns values, only the “performance marker” fields (`dwStartMilliSec` and `dwEndMilliSec`) are valid.

```
typedef struct SndSmfOptionsType {
    UInt32  dwStartMilliSec;
    UInt32  dwEndMilliSec;
    UInt16  amplitude;
    Boolean  interruptible;
    UInt8   reserved1;
    UInt32  reserved;
} SndSmfOptionsType;
```

The fields are

---

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>dwStartMilliSec</code> | The “beginning of performance” marker, measured in milliseconds from the beginning of the track. A value of 0 plays the track from the beginning. The time difference between <code>dwStartMilliSec</code> and the performance time of the first subsequent MIDI event is respected. For example, if <code>dwStartMilliSec</code> is 2000 and the first (subsequent) note-on event is at 3000, there will be a 1000 millisecond “pause” before the note is played. |
| <code>dwEndMilliSec</code>   | The “end of performance” marker, measured in milliseconds from the beginning of the track. To play to the end of the track, set this to <a href="#"><code>sndSmfPlayAllMilliSec</code></a> .                                                                                                                                                                                                                                                                       |

---

|                            |                                                                                                                                                                                                                                                     |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>amplitude</code>     | Specifies the volume of the track, in the range [0, <code>sndMaxAmp</code> ]. The default is <code>sndMaxAmp</code> . If set to 0, the MIDI file isn't played.                                                                                      |
| <code>interruptible</code> | If <code>true</code> (the default), MIDI playback is interrupted if the user interacts with the controls (digitizer, buttons, etc.), even if the interaction doesn't generate a sound command. If <code>false</code> , playback is not interrupted. |
| <code>reserved1</code>     | Reserved.                                                                                                                                                                                                                                           |
| <code>reserved</code>      | Reserved. Set this field to 0.                                                                                                                                                                                                                      |

---

## **sndSmfPlayAllMilliSec**

Represents the (temporal) far end of a MIDI file. You can use this constant as the value of the `dwEndMilliSec` field of the [SndSmfOptionsType](#) structure before passing the structure to [SndPlaySmf](#). This setting tells the function to play the entire file.

```
#define sndSmfPlayAllMilliSec 0xFFFFFFFFFUL
```

## **SndSysBeepTag**

Constants that represent a set of pre-defined system beeps. See [SndPlaySystemSound](#) for more information on the system beeps and their intended uses.

```
typedef enum SndSysBeepTag {  
    sndInfo = 1,  
    sndWarning,  
    sndError,  
    sndStartUp,  
    sndAlarm,  
    sndConfirmation,  
    sndClick  
};
```

## Simple Sound Functions

### **SndCreateMidiList**

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |

Pass 0 to search all databases.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |
| -> multipleDBs       | Pass true to search multiple databases for MIDI records. Pass false to search only in the first database that meets the search criteria.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |
| <- recordCount       | Returns the number of MIDI records that were found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |
| <- recordList        | Returns a pointer to an array of <a href="#">SndMidiListItemType</a> structures, one structure for each record that was found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |
| <b>Result</b>        | Return true if records were found, otherwise returns false.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |
| <b>Compatibility</b> | Implemented in Palm OS 3.0 and later.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |            |                                                                                                          |                |                                                                                                                                          |                |                                                     |               |                                                                                                                                |

## SndDoCmd

**Purpose** Asks the Sound Manager to perform a simple sound synthesis operation.

**Prototype** `Err SndDoCmd (void* channel,  
SndCommandPtr command, Boolean noWait)`

**Parameters**

|                            |                                                                                                                      |
|----------------------------|----------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; channel</code> | A pointer to the sound channel on which you want to perform the operation. Pass NULL for the “shared” sound channel. |
|----------------------------|----------------------------------------------------------------------------------------------------------------------|

---

**IMPORTANT:** The Sound Manager only supports one channel of sound synthesis: You must pass NULL as the value of channel.

---

|                            |                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; command</code> | Pointer to a <a href="#">SndCommandType</a> that describes the operation and associated parameters. See <b>Comments</b> , below, for information on the sound commands. |
| <code>-&gt; noWait</code>  | Sets the function to be asynchronous ( <code>true</code> ) or synchronous ( <code>false</code> ) with respect to the caller.                                            |

---

**IMPORTANT:** `SndDoCmd` is always synchronous: The `noWait` value is currently ignored.

---

|               |                                                        |
|---------------|--------------------------------------------------------|
| <b>Result</b> | <code>errNone</code> Success.                          |
|               | <code>sndErrBadParam</code> Invalid parameter.         |
|               | <code>sndErrBadChannel</code> Invalid channel pointer. |
|               | <code>sndErrQFull</code> The sound queue is full.      |

## Sound Manager

### Simple Sound Functions

---

**Comments** The sound operations that are performed by `SndDoCmd` are encapsulated in the [SndCommandType](#) structure:

```
typedef struct SndCommandType {
    SndCmdIDType cmd;
    UInt8 reserved;
    Int32 param1;
    UInt16 param2;
    UInt16 param3;
} SndCommandType;
```

The `cmd` field represents the operation; the `paramN` fields are data that's passed to the operation. The operations and data that `SndDoCmd` supports are described below:

| <b>cmd Value</b>                                                                                                                                                                | <b>param Values</b>                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>sndCmdFreqDurationAmp</code> plays a tone. The function blocks until the tone has finished.                                                                               | <code>param1</code> is the tone's frequency in Hertz.<br><code>param2</code> is its duration in milliseconds<br><code>param3</code> is its amplitude in the range <code>[0, sndMaxAmp]</code> . If the amplitude is 0, the sound isn't played and the function returns immediately. |
| <code>sndCmdFrqOn</code> initiates a tone. The function returns immediately while the tone plays in the background. Subsequent sound playback requests will interrupt the tone. | Same as the parameters for <code>sndCmdFreqDurationAmp</code> .                                                                                                                                                                                                                     |

| cmd Value                                                                                                                                                                                            | param Values                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><code>sndCmdNoteOn</code> initiates a MIDI-defined tone. The function returns immediately while the tone plays in the background. Subsequent sound playback requests will interrupt the tone.</p> | <p><code>param1</code> is the tone's pitch given as a MIDI key number in the range [0, 127].<br/> <code>param2</code> is the tone's duration in milliseconds<br/> <code>param3</code> is its amplitude given as MIDI velocity [0, 127].</p> |
| <p><code>sndCmdQuiet</code> stops the playback of the currently generated tone.</p>                                                                                                                  | <p>Ignored.</p>                                                                                                                                                                                                                             |

**Compatibility** Commands other than `sndCmdFreqDurationAmp` are implemented in Palm OS 3.0 and later. In OS versions earlier than 3.0, `SndDoCmd` will crash with a fatal error if you pass a command other than `sndCmdFreqDurationAmp`.

**See Also** [SndPlaySmf](#)

## SndGetDefaultVolume

**Purpose** Returns volume levels cached by the Sound Manager.

**Prototype** `void SndGetDefaultVolume (UInt16 *alarmAmp, UInt16 *sysAmp, UInt16 *masterAmp)`

**Parameters**

- <- `alarmAmp` Pointer to the alarm amplitude.
- <- `sysAmp` Pointer to the system sound amplitude.
- <- `masterAmp` Pointer to the master amplitude.

**Comments** Pass NULL for settings that you don't care about.

**Compatibility** Never call this function in Palm OS 5. To retrieve default volume levels, you should ask for the user's preferences settings.

**See Also** [SndSetDefaultVolume](#)

## **SndInterruptSmfIrregardless**

- Purpose** Stops the currently playing MIDI file, even if the performance was declared to be intolerant of interruptions.
- Prototype** `Err SndInterruptSmfIrregardless (void)`
- Result** Always returns `errNone` (success).
- Compatibility** Implemented in Palm OS 4.0 and later. The name is incompatible with the English language.
- See Also** [SndPlaySmf](#), [SndPlaySmfResourceIrregardless](#)

## **SndPlaySmf**

- Purpose** Performs a Standard MIDI File, or returns the duration of the file.
- Prototype** `Err SndPlaySmf (void *channel, SndSmfCmdEnum command, UInt8 *midiData, SndSmfOptionsType *options, SndSmfChanRangeType *channelRange, SndSmfCallbacksType *callbacks, Boolean noWait)`
- Parameters**
- |            |                                                                                                                      |
|------------|----------------------------------------------------------------------------------------------------------------------|
| -> channel | A pointer to the sound channel on which you want to perform the MIDI file. Pass NULL for the “shared” sound channel. |
|------------|----------------------------------------------------------------------------------------------------------------------|

---

**IMPORTANT:** The Sound Manager only supports one channel of sound synthesis: You must pass NULL as the value of channel.

---

- |             |                                                                                                                                        |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
| -> command  | Either <code>SndSmfCmdPlay</code> (play the file) or <code>SndSmfCmdDuration</code> (return the duration of the file in milliseconds). |
| -> midiData | The MIDI data; this can point to an <a href="#">SndMidiRecHdrType</a> struct, or it can point                                          |

|                 |                   |                                                                                                                                                                                                                                                                     |
|-----------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 |                   | directly to the actual MIDI data bytes in memory.                                                                                                                                                                                                                   |
| -> options      |                   | A pointer to a <a href="#">SndSmfOptionsType</a> that defines performance parameters (volume, starting offset, interruption tolerance). For default behavior, pass NULL. For more information (including default settings), see <a href="#">SndSmfOptionsType</a> . |
| -> channelRange |                   | A pointer to a <a href="#">SndSmfChanRangeType</a> that specifies the range of MIDI channels (in the SMF data) to use during playback. To play all channels, pass NULL.                                                                                             |
| -> callbacks    |                   | A pointer to a <a href="#">SndSmfCallbacksType</a> that holds your callback functions. Pass NULL if you don't want any callbacks.                                                                                                                                   |
| noWait          |                   | This value is ignored. This function always finishes playing the SMF selection before returning (but see <b>Comments</b> , below).                                                                                                                                  |
| <b>Result</b>   | errNone           | Success.                                                                                                                                                                                                                                                            |
|                 | sndErrBadParam    | Invalid value passed to this function.                                                                                                                                                                                                                              |
|                 | sndErrBadChannel  | Invalid sound channel.                                                                                                                                                                                                                                              |
|                 | sndErrMemory      | Insufficient memory.                                                                                                                                                                                                                                                |
|                 | sndErrOpen        | Tried to open channel that's already open.                                                                                                                                                                                                                          |
|                 | sndErrQFull       | Can't accept more notes.                                                                                                                                                                                                                                            |
|                 | sndErrFormat      | Unsupported data format.                                                                                                                                                                                                                                            |
|                 | sndErrBadStream   | Invalid data stream.                                                                                                                                                                                                                                                |
|                 | sndErrInterrupted | Play was interrupted.                                                                                                                                                                                                                                               |

## Sound Manager

### Simple Sound Functions

---

**Comments** Although this call is always synchronous, you can register a “blocking” function that’s called periodically as the MIDI file is playing. See [SndBlockingFuncType](#) for more information.

Normally, playback is halted by events generated by user interaction with the screen, digitizer, or hardware-based buttons. You can override this behavior by setting the `interruptible` field of the `options` argument to `false`.

This function waits until any currently playing simple sound has finished before starting playback of the requested MIDI data. A similar function, [SndPlaySmfIrregardless](#), doesn’t wait: It interrupts the current performance and immediately begins playback of the requested data.

**Compatibility** Implemented in Palm OS 3.0 and later.

## SndPlaySmfIrregardless

**Purpose** Like [SndPlaySmf](#), but interrupts any currently playing simple sound, regardless of that sound’s declared interruption tolerance.

**Prototype**

```
Err SndPlaySmfIrregardless (void *channel,  
SndSmfCmdEnum command, UInt8 *midiData,  
SndSmfOptionsType *options,  
SndSmfChanRangeType *channelRange,  
SndSmfCallbacksType *callbacks, Boolean noWait)
```

**Comments** For further information, see [SndPlaySmf](#).

**Compatibility** Implemented in Palm OS 4.0 and later.

## SndPlaySmfResource

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                              |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Plays a MIDI track read out of an open resource database.                                                                                                                                                                                                                                                                                                                                                                                                                     |                                                                                              |
| <b>Prototype</b>     | <code>Err SndPlaySmfResource (UInt32 resType, Int16 resID, SystemPreferencesChoice volume)</code>                                                                                                                                                                                                                                                                                                                                                                             |                                                                                              |

| <b>Comments</b>      | This function plays the entire MIDI file using all MIDI channels. Playback is interrupted by a key down or digitizer event. No callbacks are specified.<br><br>This function waits until any currently playing simple sound has finished before starting playback of the requested MIDI data. A similar function, <a href="#">SndPlaySmfResourceIrregardless</a> , doesn't wait: It interrupts the current performance and immediately begins playback of the requested data. |                                                                                              |
| <b>Compatibility</b> | Implemented in Palm OS 3.2 and later.                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                                                                              |

## **SndPlaySmfResourceIrregardless**

- Purpose** Like [SndPlaySmfResource](#), but interrupts any currently playing simple sound, regardless of that sound's declared tolerance for interruption.
- Prototype** `Err SndPlaySmfResourceIrregardless  
(UInt32 resType, Int16 resID,  
SystemPreferencesChoice volumeSelector)`
- Comments** For further information, see [SndPlaySmfResource](#).
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

## **SndPlaySystemSound**

- Purpose** Plays a pre-defined (simple) system sound.
- Prototype** `void SndPlaySystemSound (SndSysBeepType beepID)`
- Parameters** `-> beepID` One of the system beep sound constants, listed below.
- Comments** The system beep sounds are represented by the `SndSysBeepType` constants:
- `sndInfo`. Heralds non-crucial information.
  - `sndWarning`. Grabs the user's attention
  - `sndError`. Indicates an illegal operation.
  - `sndStartUp`. Played at device start up time.
  - `sndAlarm`. Generic alarm sound; note that this is *not* the Datebook's alarm sound.
  - `sndConfirmation`. Indicates approval or acceptance.
  - `sndClick`. The button click sound.
- If you're playing an alarm (`sndAlarm`), the user's alarm volume preference setting is used. For all other system sounds, the system volume preference is used.

In addition, `sndAlarm` sounds are played synchronously (the function blocks). All other sounds are played asynchronously.

## **SndSetDefaultVolume**

| -> <code>alarmAmp</code>  | Pointer to the alarm amplitude.                                                                                                                                                                                                                                                       |                          |                                 |                        |                                        |                           |                                  |
| -> <code>sysAmp</code>    | Pointer to the system sound amplitude.                                                                                                                                                                                                                                                |                          |                                 |                        |                                        |                           |                                  |
| -> <code>masterAmp</code> | Pointer to the master amplitude.                                                                                                                                                                                                                                                      |                          |                                 |                        |                                        |                           |                                  |
| <b>Result</b>             | Returns nothing.                                                                                                                                                                                                                                                                      |                          |                                 |                        |                                        |                           |                                  |
| <b>Comments</b>           | Any of the arguments may be <code>NULL</code> . In that case, the corresponding setting is not altered.                                                                                                                                                                               |                          |                                 |                        |                                        |                           |                                  |
| <b>Compatibility</b>      | Never call this function in Palm OS 5.                                                                                                                                                                                                                                                |                          |                                 |                        |                                        |                           |                                  |
| <b>See Also</b>           | <a href="#">SndGetDefaultVolume</a>                                                                                                                                                                                                                                                   |                          |                                 |                        |                                        |                           |                                  |

## **Simple Sound Application-Defined Functions**

### **SndBlockingFuncType**

|                          |                                                                                                                                                                                                                                                                                                        |                         |                                                                                                        |                          |                                                                         |
|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|--------------------------------------------------------------------------------------------------------|--------------------------|-------------------------------------------------------------------------|
| <b>Purpose</b>           | Invoked periodically during SMF playback.                                                                                                                                                                                                                                                              |                         |                                                                                                        |                          |                                                                         |
| <b>Prototype</b>         | <code>Boolean SndBlockingFuncType (void* channel, UInt32 userData, Int32 time)</code>                                                                                                                                                                                                                  |                         |                                                                                                        |                          |                                                                         |
| <b>Parameters</b>        | <table><tr><td>-&gt; <code>channel</code></td><td>A pointer to the sound channel on which the file is being played. Currently always <code>NULL</code>.</td></tr><tr><td>-&gt; <code>userData</code></td><td>Arbitrary data that's defined when the callback function is registered.</td></tr></table> | -> <code>channel</code> | A pointer to the sound channel on which the file is being played. Currently always <code>NULL</code> . | -> <code>userData</code> | Arbitrary data that's defined when the callback function is registered. |
| -> <code>channel</code>  | A pointer to the sound channel on which the file is being played. Currently always <code>NULL</code> .                                                                                                                                                                                                 |                         |                                                                                                        |                          |                                                                         |
| -> <code>userData</code> | Arbitrary data that's defined when the callback function is registered.                                                                                                                                                                                                                                |                         |                                                                                                        |                          |                                                                         |

## Sound Manager

### Simple Sound Application-Defined Functions

---

-> `time`            The amount of time, in milliseconds, available for completion of this function.

**Result**            If the function returns `true`, playback continues. If it returns `false`, playback is aborted.

**Comments**        Your `SndBlockingFuncType` function is called whenever the MIDI parser is “between notes.” You can do whatever you want during this period, as long as it doesn’t take more than `time` milliseconds.

**See Also**        [SndComplFuncType](#) for an example of how to register MIDI callback functions.

## SndComplFuncType

**Purpose**            Invoked immediately after a MIDI file (SMF) finishes playing.

**Prototype**        `void SndComplFuncType (void* channel, UInt32 userData)`

**Parameters**      -> `channel`            A pointer to the sound channel on which the file was played; currently always `NULL`.

                     -> `userData`            Caller-defined data that’s copied when the callback is registered.

**Comments**        To register a `SndComplFuncType` function (and the `userData` that’s fed to it), you define a [SndCallbackInfoType](#) structure, load that structure into the `completion` field of a [SndSmfCallbacksType](#) structure, and then pass *that* structure to [SndPlaySmf](#).

The following example shows how to register a completion function as well as an SMF “blocking” function ([SndBlockingFuncType](#)).

---

```
/* First, we create and load two SndCallbackInfoType structs. We assume that
MyCompletionFunc is a valid SndComplFuncType implementation, and that
MyBlockingFunc is a valid SndBlockingFuncType.
*/
```

```

SndCallbackInfoType completionFunc, blockingFunc;
completionFunc.funcP = MyCompletionFunc;
completionFunc.dwUserData = 47;
blockingFunc.funcP = MyBlockingFunc;
blockingFunc.dwUserData = (UInt32)&(char *)"we're done";

/* Next, we create an SndSmfCallbacksType struct and load the previous structs
into it.
*/
SndSmfCallbacksType callbacks;
callbacks.completion = completionFunc;
callbacks.blocking = blockingFunc;

/* Finally, we pass the callbacks into SndPlaySmf.
*/
SndPlaySmf(NULL, sndSmfCmdPlay, smf, NULL, NULL, callbacks, true);

```

---

## Sampled Sound Structures, Constants, and Data Types

### **New** SndPtr

Type used to cast a pointer to the sound data used by [SndPlayResource](#).

```
typedef void *SndPtr;
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

### **New** SndSampleType

Data type that's used for [SndSampleTypeTag](#) values.

```
typedef Enum16 SndSampleType;
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## Sound Manager

Sampled Sound Structures, Constants, and Data Types

---

### **New** SndSampleTypeTag

Constants that represent the sample format (size, data type, endianness) of a sampled sound stream. Used by [SndStreamCreate](#).

The enumeration is defined as:

```
typedef enum SndSampleTypeTag {
    sndInt8 = 0x01,
    sndUInt8 = 0x11,
    sndInt16Big = 0x02,
    sndInt16Little = 0x12,
    sndInt32Big = 0x04,
    sndInt32Little = 0x14,
    sndFloatBig = 0x24,
    sndFloatLittle = 0x34,
#if CPU_ENDIAN == CPU_ENDIAN_BIG
    sndInt16 = sndInt16Big,
    sndInt16Opposite = sndInt16Little,
    sndInt32 = sndInt32Big,
    sndInt32Opposite = sndInt32Little,
    sndFloat = sndFloatBig,
    sndFloatOpposite= sndFloatLittle
#else
    sndInt16 = sndInt16Little,
    sndInt16Opposite = sndInt16Big,
    sndInt32 = sndInt32Little,
    sndInt32Opposite= sndInt32Big,
    sndFloat = sndFloatLittle,
    sndFloatOpposite= sndFloatBig
#endif
};
```

The constants are:

---

|                                 |                                                                                                  |
|---------------------------------|--------------------------------------------------------------------------------------------------|
| sndInt8, sndUInt8               | Signed and unsigned 8-bit data.                                                                  |
| sndInt16, sndInt32,<br>sndFloat | 16-bit integer, 32-bit integer,<br>and floating point data in the<br>device's native endianness. |

|                                                                                                   |                                           |
|---------------------------------------------------------------------------------------------------|-------------------------------------------|
| <code>sndInt16Opposite,</code><br><code>sndInt32Opposite,</code><br><code>sndFloatOpposite</code> | The same as the above, but byte-swapped.  |
| <code>sndInt16Big,</code><br><code>sndInt32Big,</code><br><code>sndFloatBig</code>                | The same as the above, but big-endian.    |
| <code>sndInt16Little,</code><br><code>sndInt32Little,</code><br><code>sndFloatLittle</code>       | The same as the above, but little-endian. |

Note that the lower four bits of these constants gives the size (in bytes) of a single sample, thus:

---

```
UInt8 byteSize = formatConstant & 0x0f
```

---

---

**NOTE:** In Palm OS 5, the 32-bit and floating point formats aren't supported.

---

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

  
**New**

---

### **SndStreamMode**

Data type that's used for [SndStreamModeTag](#) values.

```
typedef Enum8 SndStreamMode;
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

  
**New**

---

### **SndStreamModeTag**

Constants that represent the "direction" (input or output) of a sampled sound stream. Used by the [SndStreamCreate](#) function.

```
typedef enum SndStreamModeTag {
```

## Sound Manager

*Sampled Sound Structures, Constants, and Data Types*

---

```
    sndInput ,  
    sndOutput  
};
```

The constants are:

---

|                        |                                  |
|------------------------|----------------------------------|
| <code>sndInput</code>  | Input stream used for recording. |
| <code>sndOutput</code> | Output stream used for playback. |

---

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**New**

---

### SndStreamRef

Data type that represents a sampled stream. You create an `SndStreamRef` through [SndStreamCreate](#).

```
typedef UInt32 SndStreamRef;
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**New**

---

### SndStreamWidth

Data type that's used for [SndStreamWidthTag](#) values.

```
typedef Enum8 SndStreamWidth;
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**New**

---

### SndStreamWidthTag

Constants that represent mono and stereo sampled data streams. Used by the [SndStreamCreate](#) function.

```
typedef enum SndStreamWidthTag {
    sndMono,
    sndStereo
};
```

The constants are:

---

|           |                              |
|-----------|------------------------------|
| sndMono   | Mono (one channel) stream.   |
| sndStereo | Stereo (two channel) stream. |

---

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**New**

---

## Sound Resource Playback Flags

Flags used by [SndPlayResource](#).

```
#define sndFlagSync 0x00000000
#define sndFlagAsync 0x00000001
#define sndFlagNormal sndFlagSync
```

See [SndPlayResource](#) for information on these flags.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**New**

---

## Stereo Pan Constants

The stereo pan settings can be used in [SndStreamSetPan](#).

```
#define sndPanCenter (0)
#define sndPanFullLeft (-1024)
#define sndPanFullRight (1024)
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

---

## Volume Constants

The volume constants can be used by [SndStreamSetVolume](#) and [SndPlayResource](#). The constants tell the functions to retrieve the named sound volume preference (as set by the user) and apply it as a volume setting.

```
enum
{
    sndSystemVolume = -1,
    sndGameVolume = -2,
    sndAlarmVolume = -3
};
```

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

## Sampled Sound Functions

---

## SndPlayResource

**Purpose** Plays formatted sound data read from a resource or file.

**Prototype** `Err SndPlayResource (SndPtr sound, Int32 ampScale, UInt32 flags)`

**Parameters**

|             |                                                                                                                                                                                                                            |
|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> sound    | A pointer to the beginning of the formatted sound (header and all). Currently, only WAVE data is recognized (see <b>Comments</b> , below); in this case, sound must point to the “RIFF” ID (byte 0 in a simple .wav file). |
| -> ampScale | Amplitude scalar, in the range [0, 32k]. See <a href="#">SndStreamSetVolume</a> for information on how amplitude scalar values are applied.                                                                                |
| -> flags    | Settings flags. Currently, the only setting is function synchronization: Choose between                                                                                                                                    |

`sndFlagSync` and `sndFlagAsync`. The former tells the function to wait until all sound data has been fed to the DAC before returning (i.e. the function will return just a bit before the sound has finished playing). The `sndFlagAsync` flag tells the function to return immediately while playback continues in a separate thread.

As a convenience, the `sndFlagNormal` value is a shorthand for the set of “normal” flag settings. Currently, this is set to `sndFlagSync`.

|               |                             |                                                              |
|---------------|-----------------------------|--------------------------------------------------------------|
| <b>Result</b> | <code>errNone</code>        | Success.                                                     |
|               | <code>sndErrBadParam</code> | sound contains no data.                                      |
|               | <code>sndErrFormat</code>   | The data is in an unsupported format.                        |
|               | <code>sndErrMemory</code>   | The function couldn't allocate sufficient memory.            |
|               | <i>other errors</i>         | The device couldn't allocate system resources for the sound. |

**Comments** Supported WAVE parameters are:

- uncompressed (PCM) or IMA 4-bit adaptive differential (IMA ADPCM). The ADPCM type is also known as DVI ADPCM; in a WAVE file, it's known as format 0x11.
- One or two-channels
- All normal sampling rates (8k, 11k, 22.05k, 44.1k, 48, 96k).

You can't interrupt or abort a resource playback once it's been initiated. The resource always play to the end of the data.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

  
**New**

---

**SndStreamCreate**

**Purpose** Creates a new audio data stream that can be used to record or playback uncompressed, sampled audio data.

**Prototype** `Err SndStreamCreate (SndStreamRef *stream, SndStreamMode mode, UInt32 sampleRate, SndSampleType type, SndStreamWidth width, SndStreamBufferCallback callback, void *callbackArg, UInt32 bufferSize, Boolean callbackIsARM)`

**Parameters**

|                                |                                                                                                                                                                      |
|--------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&lt;- stream</code>      | Token that represents the newly created stream.                                                                                                                      |
| <code>-&gt; mode</code>        | Constant that represents the “direction” of the data. Either <code>sndInput</code> (for recording), or <code>sndOutput</code> (for playback).                        |
| <code>-&gt; sampleRate</code>  | Sampling rate, in frames-per-second. The value passed here is the native rate of the data, given as a number (22050, 44100, 48000, etc.). The maximum rate is 96000. |
| <code>-&gt; type</code>        | Sample quantization and endianness (but see the section on “ <a href="#">Data Formats</a> ,” below).                                                                 |
| <code>-&gt; width</code>       | A constant that represents the number of channels of data in the stream; either <code>sndMono</code> or <code>sndStereo</code> .                                     |
| <code>-&gt; callback</code>    | A callback function that gets called when another buffer of data is needed.                                                                                          |
| <code>-&gt; callbackArg</code> | Caller-defined data that gets passed to <code>callback</code> .                                                                                                      |
| <code>-&gt; bufferSize</code>  | Preferred size (in frames) for the buffers that are passed to <code>callback</code> . Note that the actual size may be different.                                    |

-> `callbackIsARM`

(68k only) Pass `true` if the callback function is written in ARM-native code; if it's 68k, pass `false`.

**Result**

`errNone`

Success.

`sndErrBadParam`

stream is invalid, `bufferFunc` is `NULL`, the `sampleRate` is too high (greater than 96000), or the device doesn't like some other sound parameter value.

`sndErrorMemory`

All streams are being used (there is a maximum of 16), or memory for this stream couldn't otherwise be allocated.

*other errors*

The device couldn't allocate system resources for the stream.

**Comments**

This function creates a new audio stream into which you can write (playback) or from which you can read (record) buffers of uncompressed, sampled audio data. The stream's "direction"—whether it will be used for recording or playback—is described by the `mode` argument.

You can create one input stream and as many as 15 output streams. The "active" end of a stream is hardwired to read from or write to the device's sound driver. This means you can't "redirect" an input stream to read from a file (for example), nor can you connect one output stream to another output stream in an attempt to create a filter chain. You can, however, collect data from the input stream, manipulate it, and then write it to an output stream.

**Data Formats**

The format of the data that flows through the stream is described by the `sampleRate`, `type`, and `width` arguments:

- The data format that you specify for an input stream must match the data that's produced by the audio hardware.

## Sound Manager

### Sampled Sound Functions

---

- For an output stream, you can specify any of the formats that the Sound Manager supports; the data is automatically converted to the output hardware's native audio format. Whether your stream's format setting actually affects the hardware is undefined. For example, if you set an output stream to use a 48k sampling rate, that doesn't mean that the DAC will be set to 48k.

If you look at the [SndSampleTypeTag](#) constants, you'll see three flavors for each quantization type: There's a big-endian version, a little-endian version, and a native-endian version (defined as one of the other two). In general, you should use the native-endian version when choosing a value for the `type` parameter. The one exception to this (in Palm OS 5) is if your application is written for 68k, but uses an ARM `callback` function (i.e. `callbackIsARM == true`). In this case you should use one of the little-endian formats as the `type` value when you create your stream.

### Running the Stream

The new stream starts running when you pass the `stream` token returned by this function to the [SndStreamStart](#) function. This initiates a series of calls to your `callback` function, which is where the action is: Each `callback` invocation is passed a buffer into which you write or from which you read a chunk of audio data. The `callback` function is also passed the `callbackArg` that you supply here. See [SndStreamBufferCallback](#) for more information on the `callback` function.

### Buffering and Latency

Currently, audio streams are double-buffered. With regard to playback, this means that while one buffer (buffer A) is being played, your `callback` function is placing data in the other buffer (B). When A is "empty," the Sound Manager seamlessly starts playing buffer B, and passes buffer A back to your `callback`; when B is empty, the Manager start playing A, and passes back B, and so on. It's important that your `callback` function fills the data buffers as quickly as possible—certainly no longer than it takes to play a buffer of data. This same double-buffer scheme is also applied to sound recording although, of course, for recording you're emptying each buffer (and doing something with the data) in your `callback` function.

Regarding latency, you can use the `bufferSize` argument to suggest a buffer size and thereby increase or decrease latency, but you can't change the number of buffers. Keep in mind that the actual buffer size that's used may not be the same as the size you suggest; hardware and memory limitations may enforce a maximum or minimum buffer size. Also keep in mind that the `bufferSize` is measured in frames (not bytes).

[SndStreamStart](#), [SndStreamDelete](#),  
[SndStreamBufferCallback](#)

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

---

## **New** **SndStreamDelete**

**Purpose** Stops the stream and destroys it.

**Prototype** `Err SndStreamDelete (SndStreamRef stream)`

**Parameters** `-> stream` Stream token, as returned through [SndStreamCreate](#).

**Result** `errNone` Success.  
`sndErrBadParam` stream is invalid.

**Comments** [SndStreamStop](#) is called before the stream is destroyed. You should never call this function as part of the implementation of a callback function.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

---

## **New** **SndStreamGetPan**

**Purpose** Retrieves a stream's stereo balance.

**Prototype** `Err SndStreamGetPan (SndStreamRef stream,  
Int32 *pan)`

**Parameters**

|           |                                                                                     |
|-----------|-------------------------------------------------------------------------------------|
| -> stream | Stream token, as returned through <code>SndCreateRawStream</code> .                 |
| <- pan    | Pan value in the range [-1024 (hard left), 1024 (hard right)]. Center balance is 0. |

**Result**

|                |                                 |
|----------------|---------------------------------|
| errNone        | Success.                        |
| sndErrBadParam | Invalid stream, or pan is NULL. |

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**See Also** [SndStreamSetPan](#)

---

## **New** **SndStreamGetVolume**

**Purpose** Retrieves the amplitude scalar for a sound stream.

**Prototype** `Err SndStreamGetVolume (SndStreamRef stream,  
Int32 *ampScale)`

**Parameters**

|             |                                                                                                       |
|-------------|-------------------------------------------------------------------------------------------------------|
| -> stream   | Stream token, as returned through <code>SndCreateRawStream</code> .                                   |
| <- ampScale | Amplitude scalar, in the range [0, 32k]. See <a href="#">SndStreamSetVolume</a> for more information. |

**Result**

|         |          |
|---------|----------|
| errNone | Success. |
|---------|----------|

`sndErrBadParam`  
Invalid stream, or volume is NULL.

**See Also** [SndStreamSetVolume](#)

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

---

## **New** **SndStreamPause**

**Purpose** Pauses and resumes a sample stream.

**Prototype** `Err SndStreamPause (SndStreamRef stream,  
Boolean pause)`

**Parameters**

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <code>-&gt; stream</code> | Stream token, as returned by <a href="#">SndStreamCreate</a> .                |
| <code>-&gt; pause</code>  | If true, the function pauses the stream; if it's false, it resumes the stream |

**Result**

|                             |                                                                                                           |
|-----------------------------|-----------------------------------------------------------------------------------------------------------|
| <code>errNone</code>        | Success. Note that <code>errNone</code> is returned even if the stream is already in the requested state. |
| <code>sndErrBadParam</code> | Invalid stream.                                                                                           |

**Comments** Currently, `SndStreamPause` is implemented through calls to [SndStreamStop](#) and [SndStreamResume](#) (the former if `pause==true`; the latter if `pause==false`). See those functions for details about “pausing” and “resuming” a sound stream.  
You can't nest pauses; a single resume request is effective, regardless of the number of times the stream has been told to pause.

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

---

**New SndStreamSetPan**

**Purpose** Sets a stream's stereo balance.

**Prototype** `Err SndStreamSetPan (SndStreamRef stream, Int32 pan);`

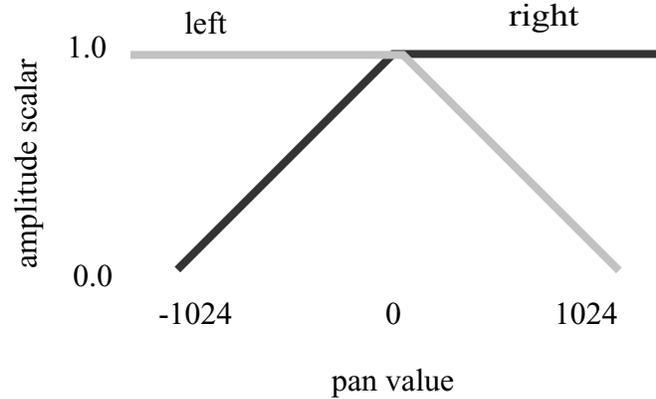

**Parameters**

|           |                                                                                                                                                                                                                                                                                             |
|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> stream | Stream token, as returned through SndCreateRawStream.                                                                                                                                                                                                                                       |
| -> pan    | Pan value in the range [-1024 (full left), 1024 (full right)]. Center balance is 0. As a convenience, you can use the values described in " <a href="#">Stereo Pan Constants</a> ." Note that values outside of the valid range may yield unexpected results (but don't generate an error). |

**Result**

|                |                 |
|----------------|-----------------|
| errNone        | Success.        |
| sndErrBadParam | Invalid stream. |

**Comments** The pan value is used as a scalar on a channel's volume such that a channel increases from 0 (inaudible) to full volume as the pan value moves from an extreme to 0. Graphically, it looks like this:

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

**See Also** [SndStreamGetPan](#)

---

## **New** SndStreamSetVolume

**Purpose** Sets the amplitude scalar for a sound stream.

**Prototype** `Err SndStreamSetVolume (SndStreamRef stream, Int32 ampScale);`

**Parameters**

- > stream      Stream token, as returned through SndCreateRawStream.
- > ampScale    Amplitude scalar in the range [0, 32k]. Values less than 0 are converted to 1024 (unity gain).

**Result**

- errNone            Success.
- sndErrBadParam    Invalid stream.

**Comments** The ampScale value is applied as an amplitude scalar on the samples that this stream's callback function produces. The scalar is

## Sound Manager

### Sampled Sound Functions

---

in the range [0, 32k], where 1024 is unity gain (i.e. the samples are multiplied by 1.0). The mapping of `ampScale` to scalar is linear; thus a volume of 512 scales the samples by  $\sim.5$ , 2048 scales by  $\sim 2.0$ , and so on.

To specify a user preference volume setting, use one of `sndSystemVolume`, `sndGameVolume`, or `sndAlarmVolume`. These values are guaranteed to be less than unity gain.

If the stream is stereo, both channels are scaled by the same amplitude scalar. To adjust the balance between the channels, use [SndStreamSetPan](#).

**Compatibility** Implemented if [Sound Stream Feature Set](#) is present.

---

## **New** SndStreamStart

**Purpose** Starts a sample stream running.

**Prototype** `Err SndStreamStart (SndStreamRef stream);`

**Parameters** `-> stream` Stream token, as returned by [SndStreamCreate](#).

**Result** `errNone` Success. Note that `errNone` is returned even if the stream is already running.

`sndErrBadParam`  
stream is invalid.

**Comments** If the stream is already running, the function returns immediately (with `errNone`). If it isn't running, the function starts the stream by initiating invocations of its callback function. If it's paused (through [SndStreamPause](#)), the stream is resumed.

You can call this function from some other stream's callback function. In other words, a stream can tell another stream to start playing.

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

  
**New**

---

## **SndStreamStop**

**Purpose**            Stops a sample stream running.

**Prototype**        `Err SndStreamStop (SndStreamRef stream);`

**Parameters**      `-> stream`            Stream token, as returned by [SndStreamCreate](#).

**Result**            `errNone`                Success. Note that `errNone` is returned even if the stream has already been stopped.  
  
                      `sndErrBadParam`        `stream` is invalid.

**Comments**        Stops a running sound stream by neglecting to call its callback function. The stream remains in this suspended state until you call [SndStreamStart](#).  
  
                      You can call this function from the stream's own callback function. In other words, a stream can stop itself.

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

## Sampled Sound Application-Defined Functions

---

### **New** SndStreamBufferCallback

**Purpose** Used to deliver a data buffer from/into which you read/write sound data.

**Prototype** `Err SndStreamBufferCallback (void *userData, SndStreamRef stream, void *buffer, UInt32 frameCount);`

**Parameters**

- > `userData` Caller-defined data, as provided by the `callbackArg` parameter to [SndStreamCreate](#).
- > `stream` Token that represents the stream that this buffer belongs to.
- > `buffer` The data buffer.
- > `frameCount` Number of sample frames the buffer contains.

**Result** Currently, the return value is ignored.

**Comments** If this is an input (recording) stream, you read the data in `buffer`. If this is an output (playback) stream, you write data into `buffer`. In either case, you want to do this as quickly as possible to avoid data underflow.

Note that the function doesn't tell you anything about the format of the data. You can use the `userData` argument to pass this information into the function.

The callback function is executed in a task that's created and managed by the Sound Manager. Because of this, the function doesn't have access to the symbols that you create in your application. Again, use the `userData` argument if you need to pass pointers to your symbols.

**Compatibility**    Implemented if [Sound Stream Feature Set](#) is present.

**See Also**        [SndStreamCreate](#)

## **Sound Manager**

*Sampled Sound Application-Defined Functions*

---

# Standard IO

---

This chapter provides reference material for the standard IO API:

- [Standard IO Functions](#)
- [Standard IO Provider Functions](#)
- [Application-Defined Function](#)

The header files `StdIOPalm.h` and `StdIOProvider.h` declare the standard IO API. For more information on using the standard IO API, see the chapter “[Standard IO Applications](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## Standard IO Functions

The macros and functions in this section enable standard IO.

### fgetc

|                    |                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Macro that calls <a href="#">siofgetc</a> to return the next character from the input stream.                                                                                                       |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                                                                            |
| <b>Prototype</b>   | <code>fgetc (fs)</code>                                                                                                                                                                             |
| <b>Parameters</b>  | <code>-&gt; fs</code> An input stream from which to read the next character. You can specify only the value <code>stdin</code> for this parameter; alternate streams are not currently implemented. |
| <b>Result</b>      | The next character from the input stream. The return value <code>EOF</code> indicates an error occurred.                                                                                            |

## **fgets**

- Purpose** Macro that calls [Siofgets](#) to return a string from the input stream.
- Declared In** StdIOPalm.h
- Prototype** fgets (strP, maxChars, fs)
- Parameters**
- |             |                                                                                                                                                                               |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <- strP     | A pointer to the returned string.                                                                                                                                             |
| -> maxChars | The number of characters to read from the input stream, plus one for the null terminator.                                                                                     |
| -> fs       | An input stream from which to read the next character. You can specify only the value <code>stdin</code> for this parameter; alternate streams are not currently implemented. |
- Result** A pointer to the string read from the input stream. If an error or EOF occurs before any characters are read, returns `NULL`.
- Comments** The returned string is always terminated by a null character.

## **fprintf**

- Purpose** Macro that calls [Siofprintf](#) to write formatted output to an output stream.
- Declared In** StdIOPalm.h
- Prototype** fprintf (fs, formatP, ...)
- Parameters**
- |            |                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> fs      | An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented. |
| -> formatP | A pointer to a format string that controls how subsequent arguments are converted for output.                                                                                    |

-> ... Zero or more parameters to be formatted as specified by the `formatP` string.

**Result** Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported.

## **fputc**

**Purpose** Macro that calls [Siofputc](#) to write a character to the output stream.

**Declared In** StdIOPalm.h

**Prototype** `fputc (c, fs)`

**Parameters**

- > `c` A character to write to the output stream.
- > `fs` An output stream to which to write the character. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.

**Result** The character that was written. If an error occurs, the value `EOF` is returned.

## **fputs**

- Purpose** Macro that calls [Siofputs](#) to write a string to the output stream.
- Declared In** StdIOPalm.h
- Prototype** fputs (strP, fs)
- Parameters**
- |         |                                                                                                                                                           |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> strP | A pointer to the string to write.                                                                                                                         |
| -> fs   | An output stream to which to write the string. You can specify only the value stdout for this parameter; alternate streams are not currently implemented. |
- Result** Returns 0 on success and the value EOF on error.

## **getchar**

- Purpose** Macro that calls [Siofgetc](#) to read the next character from the stdin input stream.
- Declared In** StdIOPalm.h
- Prototype** getchar ()
- Result** The next character from the input stream. The return value EOF indicates an error occurred.

## **gets**

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Macro that calls <a href="#">Siogets</a> to read a string from the <code>stdin</code> input stream.                                              |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                         |
| <b>Prototype</b>   | <code>gets (strP)</code>                                                                                                                         |
| <b>Parameters</b>  | <code>&lt;- strP</code> A pointer to the returned string.                                                                                        |
| <b>Result</b>      | A pointer to the string read from the input stream. If an error or EOF occurs before any characters are read, returns <code>NULL</code> .        |
| <b>Comments</b>    | The returned string does not include a null terminator. You must ensure that the input line, if any, is sufficiently short to fit in the string. |

## **printf**

|                    |                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Macro that calls <a href="#">Sioprintf</a> to write formatted output to the <code>stdout</code> output stream.                                                                                                                                  |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <code>printf (formatP, ...)</code>                                                                                                                                                                                                              |
| <b>Parameters</b>  | <code>-&gt; formatP</code> A pointer to a format string that controls how subsequent arguments are converted for output.<br><br><code>-&gt; ...</code> Zero or more parameters to be formatted as specified by the <code>formatP</code> string. |
| <b>Result</b>      | Returns the number of characters written out (not including the null terminator used to end output strings).                                                                                                                                    |

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported. Returns a negative number if there is an error.

## **putc**

**Purpose** Macro that calls [Siofputc](#) to write a character to the output stream.

**Declared In** StdIOPalm.h

**Prototype** `putc (c, fs)`

**Parameters**

|       |                                                                                                                                                                           |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> c  | A character to write to the output stream.                                                                                                                                |
| -> fs | An output stream to which to write the character. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented. |

**Result** The character that was written. If an error occurs, the value EOF is returned.

## **putchar**

**Purpose** Macro that calls [Siofputc](#) to write a character to the `stdout` output stream.

**Declared In** StdIOPalm.h

**Prototype** `putchar (c)`

**Parameters**

|      |                                                                |
|------|----------------------------------------------------------------|
| -> c | A character to write to the <code>stdout</code> output stream. |
|------|----------------------------------------------------------------|

**Result** The character that was written. If an error occurs, the value EOF is returned.

## puts

- Purpose** Macro that calls [Sioputs](#) to write a string to the output stream stdout.
- Declared In** StdIOPalm.h
- Prototype** puts (strP)
- Parameters** -> strP                    A pointer to the string to write to stdout.
- Result** Returns a nonnegative value on success and the value EOF on error.

## SioAddCommand

- Purpose** Adds a built-in command that is supplied by the standard IO provider application.
- Declared In** StdIOPalm.h
- Prototype** void SioAddCommand (const Char \*cmdStr, SioMainProcPtr cmdProcP)
- Parameters** -> cmdStr                    Pointer to a string that is the command name.  
              -> cmdProcP                Pointer to the command entry point function (the [SioMain](#) function).
- Result** Returns nothing.
- Comments** This routine is useful for registering a command that is inside the standard IO provider application instead of in its own database. This routine must be used to test commands under the Simulator since it can't launch application databases.

## **Siofgetc**

Return the next character from the input stream.

**Declared In** StdIOPalm.h

**Prototype** Int16 Siofgetc (FILE \*fs)

**Parameters** -> fs An input stream from which to read the next character. You can specify only the value `stdin` for this parameter; alternate streams are not currently implemented.

**Result** The next character from the input stream. The return value `EOF` indicates an error occurred.

**See Also** [fgetc](#)

## **Siofgets**

**Purpose** Return a string from the input stream.

**Declared In** StdIOPalm.h

**Prototype** Char \*Siofgets (Char \*strP, UInt16 maxChars, FILE \*fs)

**Parameters** <- strP A pointer to the returned string.  
-> maxChars The number of characters to read from the input stream, plus one for the null terminator.  
-> fs An input stream from which to read the next character. You can specify only the value `stdin` for this parameter; alternate streams are not currently implemented.

**Result** A pointer to the string read from the input stream. If an error or `EOF` occurs before any characters are read, returns `NULL`.

**Comments** The returned string is always terminated by a null character.

**See Also** [fgets](#)

## Siofprintf

**Purpose** Write formatted output to an output stream.

**Declared In** StdIOPalm.h

**Prototype** `Int16 Siofprintf (FILE *fs, const Char *formatP, ...)`

**Parameters**

|            |                                                                                                                                                                                  |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> fs      | An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented. |
| -> formatP | A pointer to a format string that controls how subsequent arguments are converted for output.                                                                                    |
| -> ...     | Zero or more parameters to be formatted as specified by the <code>formatP</code> string.                                                                                         |

**Result** Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported.

**See Also** [fprintf](#)

## **Siofputc**

- Purpose** Write a character to the output stream.
- Declared In** StdIOPalm.h
- Prototype** `Int16 Siofputc (Int16 c, FILE *fs)`
- Parameters**
- > `c` A character to write to the output stream.
  - > `fs` An output stream to which to write the character. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.
- Result** The character that was written. If an error occurs, the value `EOF` is returned.
- See Also** [fputc](#)

## **Siofputs**

- Purpose** Write a string to the output stream.
- Declared In** StdIOPalm.h
- Prototype** `Int16 Siofputs (const Char *strP, FILE *fs)`
- Parameters**
- > `strP` A pointer to the string to write.
  - > `fs` An output stream to which to write the string. You can specify only the value `stdout` for this parameter; alternate streams are not currently implemented.
- Result** Returns 0 on success and the value `EOF` on error.
- See Also** [fputs](#)

## Siogets

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Read a string from the <code>stdin</code> input stream.                                                                                          |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                         |
| <b>Prototype</b>   | <code>Char *Siogets (Char *strP)</code>                                                                                                          |
| <b>Parameters</b>  | <code>&lt;- strP</code> A pointer to the returned string.                                                                                        |
| <b>Result</b>      | A pointer to the string read from the input stream. If an error or EOF occurs before any characters are read, returns <code>NULL</code> .        |
| <b>Comments</b>    | The returned string does not include a null terminator. You must ensure that the input line, if any, is sufficiently short to fit in the string. |
| <b>See Also</b>    | <a href="#">gets</a>                                                                                                                             |

## Sioprintf

|                    |                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Write formatted output to the <code>stdout</code> output stream.                                                                                                                                                                                |
| <b>Declared In</b> | <code>StdIOPalm.h</code>                                                                                                                                                                                                                        |
| <b>Prototype</b>   | <code>Int16 Sioprintf (const Char *formatP, ...)</code>                                                                                                                                                                                         |
| <b>Parameters</b>  | <code>-&gt; formatP</code> A pointer to a format string that controls how subsequent arguments are converted for output.<br><br><code>-&gt; ...</code> Zero or more parameters to be formatted as specified by the <code>formatP</code> string. |
| <b>Result</b>      | Returns the number of characters written out (not including the null terminator used to end output strings).                                                                                                                                    |

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported. Returns a negative number if there is an error.

**See Also** [printf](#)

## **Sioputs**

**Purpose** Write a string to the output stream stdout.

**Declared In** StdIOPalm.h

**Prototype** Int16 Sioputs (const Char \*strP)

**Parameters** -> strP A pointer to the string to write to stdout.

**Result** Returns a nonnegative value on success and the value EOF on error.

**See Also** [puts](#)

## **Siosystem**

**Purpose** Execute another Stdio command.

**Declared In** StdIOPalm.h

**Prototype** Int16 Siosystem (const Char \*cmdStrP)

**Parameters** -> cmdStrP A pointer to a string containing the command line to execute.

**Result** Returns a value  $\geq 0$  on success or  $< 0$  on failure.

**Comments** This function first looks for a built-in command with the specified name. If none is found, it looks for a Stdio application database with

the name "Cmd-*cmdname*" where *cmdname* is the first word in the command string `cmdStrP`.

**See Also** [SioExecCommand](#), [system](#)

## Siovfprintf

**Purpose** Write formatted output to the `stdout` output stream.

**Declared In** `StdIOPalm.h`

**Prototype** `Int16 Siovfprintf (FILE *fs, const Char *formatP, _Palm_va_list args)`

**Parameters**

|                         |                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>fs</code>      | An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented. |
| -> <code>formatP</code> | A pointer to a format string that controls how subsequent arguments are converted for output.                                                                                    |
| -> <code>args</code>    | A pointer to a list of zero or more parameters to be formatted as specified by the <code>formatP</code> string.                                                                  |

**Result** Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported.

**See Also** [vfprintf](#)

## **sprintf**

- Purpose** Macro that calls [StrPrintF](#) to write formatted output to the stdout output stream.
- Declared In** StdIOPalm.h
- Prototype** `sprintf (formatP, ...)`
- Parameters**
- |            |                                                                                               |
|------------|-----------------------------------------------------------------------------------------------|
| -> formatP | A pointer to a format string that controls how subsequent arguments are converted for output. |
| -> ...     | Zero or more parameters to be formatted as specified by the formatP string.                   |
- Result** Returns the number of characters written out (not including the null terminator used to end output strings).
- Comments** See [StrVPrintF](#) for details on which format specifications are supported. Returns a negative number if there is an error.

## **system**

- Purpose** Macro that calls [Siosystem](#) to execute another Stdio command.
- Declared In** StdIOPalm.h
- Prototype** `system (cmdStrP)`
- Parameters**
- |            |                                                               |
|------------|---------------------------------------------------------------|
| -> cmdStrP | A pointer to a string containing the command line to execute. |
|------------|---------------------------------------------------------------|
- Result** Returns a value  $\geq 0$  on success or  $< 0$  on failure.
- Comments** This function first looks for a built-in command with the specified name. If none is found, it looks for a Stdio application database with

the name "Cmd-*cmdname*" where *cmdname* is the first word in the command string `cmdStrP`.

**See Also** [SioExecCommand](#)

## **vfprintf**

**Purpose** Macro that calls [Siovfprintf](#) to write formatted output to the `stdout` output stream.

**Declared In** `StdIOPalm.h`

**Prototype** `vfprintf (fs, formatP, args)`

**Parameters**

|                         |                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>fs</code>      | An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented. |
| -> <code>formatP</code> | A pointer to a format string that controls how subsequent arguments are converted for output.                                                                                    |
| -> <code>args</code>    | A pointer to a list of zero or more parameters to be formatted as specified by the <code>formatP</code> string.                                                                  |

**Result** Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported.

| -> fs              | An output stream to which to write the formatted output. You can specify only the value <code>stdout</code> for this parameter; alternate streams are not currently implemented.                                                                                                                                                                                                                                                                                                                         |       |                                                                                                                                                                                  |            |                                                                                               |         |                                                                                              |
| -> formatP         | A pointer to a format string that controls how subsequent arguments are converted for output.                                                                                                                                                                                                                                                                                                                                                                                                            |       |                                                                                                                                                                                  |            |                                                                                               |         |                                                                                              |
| -> args            | A pointer to a list of zero or more parameters to be formatted as specified by the y string.                                                                                                                                                                                                                                                                                                                                                                                                             |       |                                                                                                                                                                                  |            |                                                                                               |         |                                                                                              |
| <b>Result</b>      | Returns the number of characters written out (not including the null terminator used to end output strings). Returns a negative number if there is an error.                                                                                                                                                                                                                                                                                                                                             |       |                                                                                                                                                                                  |            |                                                                                               |         |                                                                                              |
| <b>Comments</b>    | See <a href="#">StrVPrintf</a> for details on which format specifications are supported.                                                                                                                                                                                                                                                                                                                                                                                                                 |       |                                                                                                                                                                                  |            |                                                                                               |         |                                                                                              |

## Standard IO Provider Functions

These functions are used by a standard IO provider application.

## SioClearScreen

|                    |                                             |
|--------------------|---------------------------------------------|
| <b>Purpose</b>     | Clears the entire standard IO output field. |
| <b>Declared In</b> | <code>StdIOProvider.h</code>                |
| <b>Prototype</b>   | <code>void SioClearScreen (void)</code>     |
| <b>Parameters</b>  | None.                                       |
| <b>Result</b>      | Returns nothing.                            |

## SioExecCommand

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Executes a command line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Prototype</b>   | <code>Int16 SioExecCommand (const Char *cmd)</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | -> <code>cmd</code> A pointer to a string containing the command line to execute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Result</b>      | Returns a value $\geq 0$ on success or $< 0$ on failure.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Comments</b>    | <p>This function first looks for a built-in command with the specified name. If none is found, it looks for a Stdio application database with the name "Cmd-<i>cmdname</i>" where <i>cmdname</i> is the first word in the command string <code>cmd</code>.</p> <p>If you pass the string "help" or "?" for the <code>cmd</code> parameter, <code>SioExecCommand</code> causes a help string to be printed for each built-in command. It actually executes each built-in command, passing the string "?" as <code>argv[1]</code>. Each command should handle this argument by printing a help line.</p> <p>The <code>SioExecCommand</code> function is faster than calling <a href="#">system</a> to execute a command. However, <code>SioExecCommand</code> can be called</p> |

## Standard IO

### Standard IO Provider Functions

---

only by the standard IO provider application, not the standard IO application.

## SioFree

- Purpose** Closes down the standard IO manager.
- Declared In** StdIOProvider.h
- Prototype** Err SioFree (void)
- Parameters** None.
- Result** Returns 0 on success.

## SioHandleEvent

- Purpose** Handles an event in the form that contains the standard IO output field and scroll arrows if the event belongs to the text field or scroll arrows.
- Declared In** StdIOProvider.h
- Prototype** Boolean SioHandleEvent (SysEventType \*event)
- Parameters** -> event            Pointer to an EventType structure.
- Result** Returns true if the event was handled and should not be processed by the application's own form event handler; returns false otherwise.
- Comments** This function must be called from the form event handler before it does its own processing with any of the objects unrelated to standard IO in the form.

## **SioInit**

|                    |                                                                |                                                               |
|--------------------|----------------------------------------------------------------|---------------------------------------------------------------|
| <b>Purpose</b>     | Initializes the standard IO manager.                           |                                                               |
| <b>Declared In</b> | StdIOProvider.h                                                |                                                               |
| <b>Prototype</b>   | Err SioInit (UInt16 formID, UInt16 fieldID, UInt16 scrollerID) |                                                               |
| <b>Parameters</b>  | -> formID                                                      | The ID of the form that contains the input/output field.      |
|                    | -> fieldID                                                     | The ID of the field to be used for input/output.              |
|                    | -> scrollerID                                                  | The ID of the scroller associated with the input/output form. |
| <b>Result</b>      | Returns 0 on success.                                          |                                                               |

## Application-Defined Function

You must supply this function in your stdio application.

### **SioMain**

**Purpose** The main entry point for the stdio application.

**Declared In** StdIOPalm.h

**Prototype** `Int16 SioMain (UInt16 argc, const Char *argv[])`

**Parameters**

|         |                                                                                    |
|---------|------------------------------------------------------------------------------------|
| -> argc | The number of parameters passed on the command line.                               |
| -> argv | An array of character pointers, one for each parameter passed on the command line. |

**Result** The return value from this routine is passed back to the system call that invoked it. Return 0 for no error.

# String Manager

---

This chapter provides reference material for the string manager. The string manager API is declared in the header file `StringMgr.h`.

For more information, see [Chapter 8, “Text,”](#) on page 251 of the *Palm OS Programmer’s Companion*, vol. I.

## String Manager Functions

### StrAToI

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Purpose</b>     | Convert a string to an integer.                                      |
| <b>Declared In</b> | <code>StringMgr.h</code>                                             |
| <b>Prototype</b>   | <code>Int32 StrAToI (const Char *str)</code>                         |
| <b>Parameters</b>  | -> <code>str</code> Pointer to a string to convert.                  |
| <b>Result</b>      | Returns the integer.                                                 |
| <b>Comments</b>    | Use this function instead of the standard <code>atoi</code> routine. |

## StrCaselessCompare

- Purpose** Compare two strings with case and accent insensitivity.
- Declared In** `StringMgr.h`
- Prototype** `Int16 StrCaselessCompare (const Char *s1, const Char *s2)`
- Parameters**
- > `s1` Pointer to a string.
  - > `s2` Pointer to a string.
- Result**
- Returns 0 if the strings match.
  - Returns a positive number if `s1 > s2`.
  - Returns a negative number if `s1 < s2`.
- Comments** Use this function instead of the standard `stricmp` routine. To support systems that use multi-byte character encodings, consider using [TxtCaselessCompare](#) instead of this function (or [TxtCompare](#) for a case-sensitive comparison). Both functions can match single-byte characters with their multi-byte equivalents, but `TxtCaselessCompare` can also return the length of the matching text.
- See Also** [StrNCaselessCompare](#), [TxtCaselessCompare](#), [StrCompare](#), [StrNCompare](#)

## StrCat

- Purpose** Concatenate one null-terminated string to another.
- Declared In** `StringMgr.h`
- Prototype** `Char *StrCat (Char *dst, const Char *src)`
- Parameters**
- |                     |                                                    |
|---------------------|----------------------------------------------------|
| -> <code>dst</code> | Pointer to the null-terminated destination string. |
| -> <code>src</code> | Pointer to the null-terminated source string.      |
- Result** Returns a pointer to the destination string.
- Comments** Use this function instead of the standard `strcat` routine.

## StrChr

- Purpose** Look for a character within a string.
- Declared In** `StringMgr.h`
- Prototype** `Char *StrChr (const Char *str, WChar chr)`
- Parameters**
- |                     |                                       |
|---------------------|---------------------------------------|
| -> <code>str</code> | Pointer to the string to be searched. |
| -> <code>chr</code> | Character to search for.              |
- Result** Returns a pointer to the first occurrence of character in `str`. Returns `NULL` if the character is not found.
- Comments** Use this function instead of the standard `strchr` routine.
- This function can handle both single-byte characters and multi-byte characters correctly. However, you should make sure that you pass a `WChar` variable to `StrChr` instead of a `Char`. If you pass a `Char` variable, the function sign-extends the variable to a `WChar`, which causes problems if the value is `0x80` or higher.

## String Manager

### String Manager Functions

---

**Compatibility** This routine does not correctly find a '\0' character on Palm OS® version 1.0.

**See Also** [StrStr](#)

## StrCompare

**Purpose** Compare two strings.

**Declared In** `StringMgr.h`

**Prototype** `Int16 StrCompare (const Char *s1, const Char *s2)`

**Parameters**

- > s1                    Pointer to a string.
- > s2                    Pointer to a string.

**Result**

- Returns 0 if the strings match.
- Returns a positive number if s1 sorts after s2 alphabetically.
- Returns a negative number if s1 sorts before s2 alphabetically.

**Comments** Use this function or [StrCompareAscii](#) instead of the standard `strcmp` routine. This function is case sensitive.

To support systems that use multi-byte character encodings, consider using [TxtCompare](#) instead of this function. Both functions can match single-byte characters with their multi-byte equivalents, but `TxtCompare` can also return the length of the matching text.

**Compatibility** Prior to Palm OS 4.0, `StrCompare` and [TxtCompare](#) only performed one level of comparison and returned as soon as they found two unequal characters. For example, if you compared the string "celery" with the string "Cauliflower," both functions returned a value indicating that "celery" should appear before "Cauliflower" because they sorted "c" before "C."

In Palm OS 4.0, `StrCompare` calls `TxtCompare`, and `TxtCompare` performs a comparison using up to six comparison tables for sorting

with increasing precision. As a result, in Palm OS 4.0 and higher, `StrCompare` sorts “Cauliflower” before “celery.”

**See Also** [StrNCompare](#), [StrNCaselessCompare](#), [TxtCaselessCompare](#)

## **StrCompareAscii**

**Purpose** Compare two ASCII strings.

**Declared In** `StringMgr.h`

**Prototype** `Int16 StrCompareAscii (const Char *s1,  
const Char *s2)`

**Parameters**

|       |                      |
|-------|----------------------|
| -> s1 | Pointer to a string. |
| -> s2 | Pointer to a string. |

**Result** Returns 0 if the strings match.  
Returns a positive number if s1 sorts after s2 alphabetically.  
Returns a negative number if s1 sorts before s2 alphabetically.

**Comments** Use this function instead of the standard `strcmp` routine. Use it to do case-sensitive comparisons on strings that are guaranteed to be 7-bit ASCII strings. This function performs a fast, simple byte-to-byte comparison that is guaranteed never to change.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [StrCompare](#), [StrNCompare](#), [TxtCompare](#),  
[StrCaselessCompare](#), [StrNCaselessCompare](#),  
[TxtCaselessCompare](#), [StrNCompareAscii](#)

## String Manager

### String Manager Functions

---

## StrCopy

- Purpose** Copy one string to another.
- Declared In** `StringMgr.h`
- Prototype** `Char *StrCopy (Char *dst, const Char *src)`
- Parameters**
- > `dst` Pointer to the destination string.
  - > `src` Pointer to the source string.
- Result** Returns a pointer to the destination string.
- Comments** Use this function instead of the standard `strcpy` routine. This function does not work properly with overlapping strings.

## StrDelocalizeNumber

- Purpose** Delocalize a number passed in as a string. Convert the number from any localized notation to US notation (decimal point and thousandth comma). The current thousand and decimal separators have to be passed in.
- Declared In** `StringMgr.h`
- Prototype** `Char *StrDelocalizeNumber (Char *s, Char thousandSeparator, Char decimalSeparator)`
- Parameters**
- <-> `s` Pointer to the number as an ASCII string.
  - > `thousandSeparator` Current thousand separator.
  - > `decimalSeparator` Current decimal separator.
- Result** Returns a pointer to the changed number and modifies the string in `s`.

**Comments** The current thousandSeparator and decimalSeparator can be determined by obtaining the value of the prefNumberFormat preference using [PrefGetPreference](#) and then passing the returned [NumberFormatType](#) to [LocGetNumberSeparators](#). For example:

```
Char *localizedNum;  
NumberFormatType numFormat;  
Char thousandsSeparator, decimalSeparator;  
  
numFormat = (NumberFormatType)  
    PrefGetPreference(prefNumberFormat);  
LocGetNumberSeparators(numFormat,  
    &thousandsSeparator, &decimalSeparator);  
StrDelocalizeNumber(localizedNum,  
    thousandsSeparator, decimalSeparator);
```

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [StrLocalizeNumber](#), [LocGetNumberSeparators](#)

## StrIToA

**Purpose** Convert an integer to ASCII.

**Declared In** StringMgr.h

**Prototype** Char \*StrIToA (Char \*s, Int32 i)

**Parameters**

|      |                                                                          |
|------|--------------------------------------------------------------------------|
| <- s | Pointer to a string of size maxStrIToALen in which to store the results. |
| -> i | Integer to convert.                                                      |

**Result** Returns a pointer to the result string.

**See Also** [StrAToI](#), [StrIToH](#)

## String Manager

### String Manager Functions

---

#### StrItoH

- Purpose** Convert an integer to hexadecimal ASCII.
- Declared In** `StringMgr.h`
- Prototype** `Char *StrItoH (Char *s, UInt32 i)`
- Parameters**
- `<- s` Pointer to a string in which to store the results.
  - `-> i` Integer to convert.
- Result** Returns the string pointer `s`.
- See Also** [StrItoA](#)

#### StrLen

- Purpose** Compute the length of a string.
- Declared In** `StringMgr.h`
- Prototype** `UInt16 StrLen (const Char *src)`
- Parameters**
- `-> src` Pointer to a string.
- Result** Returns the length of the string in bytes.
- Comments** Use this function instead of the standard `strlen` routine. This function returns the length of the string in bytes. On systems that support multi-byte characters, the number returned does not always equal the number of characters.
- Compatibility** In Palm OS 3.5 and Palm OS 4.x this function was declared to return an `Int16`. In Palm OS 5, and prior to Palm OS 3.5, this function returns a `UInt16`.

## **StrLocalizeNumber**

**Purpose** Convert a number (passed in as a string) to localized format, using a specified thousands separator and decimal separator.

**Declared In** `StringMgr.h`

**Prototype** `Char *StrLocalizeNumber (Char *s,  
Char thousandSeparator, Char decimalSeparator)`

## String Manager

### String Manager Functions

---

**Parameters** <-> s                    Numeric ASCII string to localize.  
-> thousandSeparator  
                                         Localized thousand separator.  
-> decimalSeparator  
                                         Localized decimal separator.

**Result** Returns a pointer to the changed number. Converts the number string in s by replacing all occurrences of “,” with thousandSeparator and all occurrences of “.” with decimalSeparator.

**Comments** The current thousandSeparator and decimalSeparator can be determined by obtaining the value of the prefNumberFormat preference using [PrefGetPreference](#) and then passing the returned [NumberFormatType](#) to [LocGetNumberSeparators](#). For example:

```
Char *localizedNum;  
NumberFormatType numFormat;  
Char thousandsSeparator, decimalSeparator;  
  
numFormat = (NumberFormatType)  
    PrefGetPreference(prefNumberFormat);  
LocGetNumberSeparators(numFormat,  
    &thousandsSeparator, &decimalSeparator);  
StrLocalizeNumber(localizedNum,  
    thousandsSeparator, decimalSeparator);
```

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [StrDelocalizeNumber](#)

## StrNCaselessCompare

|                      |                                                                                                                                                                                                                                                                                                                                                                                    |       |                              |       |                               |      |                                         |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------------------------------|-------|-------------------------------|------|-----------------------------------------|
| <b>Purpose</b>       | Compares two strings out to <i>n</i> characters with case and accent insensitivity.                                                                                                                                                                                                                                                                                                |       |                              |       |                               |      |                                         |
| <b>Declared In</b>   | StringMgr.h                                                                                                                                                                                                                                                                                                                                                                        |       |                              |       |                               |      |                                         |
| <b>Prototype</b>     | <code>Int16 StrNCaselessCompare (const Char *s1, const Char *s2, Int32 n)</code>                                                                                                                                                                                                                                                                                                   |       |                              |       |                               |      |                                         |
| <b>Parameters</b>    | <table><tr><td>-&gt; s1</td><td>Pointer to the first string.</td></tr><tr><td>-&gt; s2</td><td>Pointer to the second string.</td></tr><tr><td>-&gt; n</td><td>Length in bytes of the text to compare.</td></tr></table>                                                                                                                                                            | -> s1 | Pointer to the first string. | -> s2 | Pointer to the second string. | -> n | Length in bytes of the text to compare. |
| -> s1                | Pointer to the first string.                                                                                                                                                                                                                                                                                                                                                       |       |                              |       |                               |      |                                         |
| -> s2                | Pointer to the second string.                                                                                                                                                                                                                                                                                                                                                      |       |                              |       |                               |      |                                         |
| -> n                 | Length in bytes of the text to compare.                                                                                                                                                                                                                                                                                                                                            |       |                              |       |                               |      |                                         |
| <b>Result</b>        | Returns 0 if the strings match.<br>Returns a positive number if <i>s1</i> > <i>s2</i> .<br>Returns a negative number if <i>s1</i> < <i>s2</i> .                                                                                                                                                                                                                                    |       |                              |       |                               |      |                                         |
| <b>Comments</b>      | To support systems that use multi-byte character encodings, consider using <a href="#">TxtCaselessCompare</a> instead of this function (or <a href="#">TxtCompare</a> for a case-sensitive comparison). Both functions can match single-byte characters with their multi-byte equivalents, but <a href="#">TxtCaselessCompare</a> can also return the length of the matching text. |       |                              |       |                               |      |                                         |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present. As of Palm OS 4.0, both <i>s1</i> and <i>s2</i> must be null-terminated strings.                                                                                                                                                                                                                               |       |                              |       |                               |      |                                         |
| <b>See Also</b>      | <a href="#">StrNCompare</a> , <a href="#">StrCaselessCompare</a> , <a href="#">TxtCaselessCompare</a> , <a href="#">StrCompare</a>                                                                                                                                                                                                                                                 |       |                              |       |                               |      |                                         |

## String Manager

### String Manager Functions

---

## StrNCat

**Purpose** Concatenates one string to another clipping the destination string to a maximum of *n* bytes (including the null character at the end).

---

**IMPORTANT:** The Palm OS implementation of `StrNCat` differs from the implementation in the standard C library. See the Comments section for details.

---

**Declared In** `StringMgr.h`

**Prototype** `Char *StrNCat (Char *dst, const Char *src, Int16 n)`

**Parameters**

|                     |                                                                                          |
|---------------------|------------------------------------------------------------------------------------------|
| -> <code>dst</code> | Pointer to the null-terminated destination string.                                       |
| -> <code>src</code> | Pointer to the source string.                                                            |
| -> <code>n</code>   | Maximum length in bytes for <code>dst</code> , including the terminating null character. |

**Result** Returns a pointer to the destination string.

**Comment** This function differs from the standard C `strncat` function in these ways:

- `StrNCat` treats the parameter `n` as the maximum length in bytes for `dst`. That means it will copy at most `n - StrLen(dst) - 1` bytes from `src`. The standard C function always copies `n` bytes from `src` into `dst`. (It copies the entire `src` into `dst` if the length of `src` is less than `n`).
- If the length of the destination string reaches `n - 1`, `StrNCat` stops copying bytes from `src` and appends the terminating null character to `dst`. If the length of the destination string is already greater than or equal to `n - 1` before the copying begins, `StrNCat` does not copy any data from `src`.
- In the standard C function, if `src` is less than `n`, the entire `src` string is copied into `dst` and then the remaining space is filled with null characters. `StrNCat` does not fill the

remaining space with null characters in released ROMs. In debug ROMs, `StrNCat` fills the remaining bytes with the value `0xFE`.

On systems with multi-byte character encodings, this function makes sure that it does not copy part of a multi-byte character. If the last byte copied from `src` contains the high-order or middle byte of a multi-byte character, `StrNCat` backs up in `dst` until the byte after the end of the previous character, and replaces that byte with a null character.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## StrNCompare

**Purpose** Compare two strings out to  $n$  bytes. This function is case and accent sensitive.

**Declared In** `StringMgr.h`

**Prototype** `Int16 StrNCompare (const Char *s1,  
const Char *s2, Int32 n)`

**Parameters**

|                    |                                     |
|--------------------|-------------------------------------|
| -> <code>s1</code> | Pointer to a string.                |
| -> <code>s2</code> | Pointer to a string.                |
| -> <code>n</code>  | Length in bytes of text to compare. |

**Result**

Returns 0 if the strings match.

Returns a positive number if  $s1 > s2$ .

Returns a negative number if  $s1 < s2$ .

**Comments** To support systems that use multi-byte character encodings, consider using [TxtCompare](#) instead of this function. Both functions can match single-byte characters with their multi-byte equivalents, but `TxtCompare` can also return the length of the matching text.

## String Manager

### String Manager Functions

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present. As of Palm OS 4.0, both `s1` and `s2` must be null-terminated strings.

**See Also** [StrCompare](#), [StrNCaselessCompare](#), [StrCaselessCompare](#), [TxtCaselessCompare](#), [StrNCompareAscii](#)

## StrNCompareAscii

**Purpose** Compare two ASCII strings out to  $n$  bytes.

**Declared In** `StringMgr.h`

**Prototype** `Int16 StrNCompareAscii (const Char *s1, const Char *s2, Int32 n)`

**Parameters**

- > `s1` Pointer to a string.
- > `s2` Pointer to a string.
- > `n` Length in bytes of text to compare.

**Result** Returns 0 if the strings match.  
Returns a positive number if `s1` sorts after `s2` alphabetically.  
Returns a negative number if `s1` sorts before `s2` alphabetically.

**Comments** Use this function instead of the standard `strncmp` routine. Use it to do case-sensitive comparisons on strings that are guaranteed to be 7-bit ASCII strings. This function performs a fast, simple byte-to-byte comparison that is guaranteed never to change.

**Compatibility** Implemented only if [4.0 New Feature Set](#) is present.

**See Also** [StrCompare](#), [StrNCompare](#), [TxtCompare](#), [StrCaselessCompare](#), [StrNCaselessCompare](#), [TxtCaselessCompare](#), [StrCompareAscii](#)

## StrNCopy

- Purpose** Copies up to  $n$  bytes from a source string to the destination string. Terminates `dst` string at index  $n-1$  if the source string length was  $n-1$  or less.
- Declared In** `StringMgr.h`
- Prototype** `Char *StrNCopy (Char *dst, const Char *src, Int16 n)`
- Parameters**
- > `dst` Pointer to the destination string.
  - > `src` Pointer to the source string.
  - > `n` Maximum number of bytes to copy from `src` string.
- Result** Returns nothing.
- Comments** On systems with multi-byte character encodings, this function makes sure that it does not copy part of a multi-byte character. If the  $n$ th byte of `src` contains the high-order or middle byte of a multi-byte character, `StrNCopy` backs up in `dst` until the byte after the end of the previous character, and replaces the remaining bytes (up to  $n-1$ ) with nulls.
- Be aware that the  $n$ th byte of `dst` upon return may contain the last byte of a multi-byte character. If you plan to terminate the string by setting its last character to `NULL`, you must not pass the entire length of the string to `StrNCopy`. If you do, your code may overwrite the final byte of the last character.
- ```
// WRONG! You may overwrite part of multi-byte
// character.
Char dst[n];
StrNCopy(dst, src, n);
dst[n-1] = chrNull;
```
- Instead, if you write to the last byte of the destination string, pass one less than the size of the string to `StrNCopy`.

## String Manager

### String Manager Functions

---

```
// RIGHT. Instead pass n-1 to StrNCopy.  
Char dst[n];  
StrNCopy(dst, src, n-1);  
dst[n-1] = chrNull;
```

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## StrPrintF

**Purpose** Implements a subset of the ANSI C `sprintf` call, which writes formatted output to a string.

**Declared In** `StringMgr.h`

**Prototype** `Int16 StrPrintF (Char *s,  
const Char *formatStr, ...)`

**Parameters**

-> s	Pointer to a string into which the results are written.
-> formatStr	Pointer to the format specification string.
...	Zero or more arguments to be formatted as specified by <code>formatStr</code> .

**Result** Number of characters written to destination string. Returns a negative number if there is an error.

**Comments** This function internally calls [StrVPrintF](#) to do the formatting. See that function for details on which format specifications are supported.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

**See Also** [StrVPrintF](#)

## StrStr

<b>Purpose</b>	Look for a substring within a string.
<b>Declared In</b>	StringMgr.h
<b>Prototype</b>	Char *StrStr (const Char *str, const Char *token)
<b>Parameters</b>	-> str                    Pointer to the string to be searched. -> token                  Pointer to the string to search for.
<b>Result</b>	Returns a pointer to the first occurrence of token in str or NULL if not found.
<b>Comments</b>	Use this function instead of the standard strstr routine.  On systems with multi-byte character encodings, this function makes sure that it does not match only part of a multi-byte character. If the matching strings begins at an inter-character boundary, then this function returns NULL.  <hr/> <b>NOTE:</b> If the value of the token parameter is the empty string, this function returns NULL. This is different than the standard strstr function, which returns str when token is the empty string. <hr/>
<b>See Also</b>	<a href="#">StrChr</a>

## StrToLower

<b>Purpose</b>	Convert all the characters in a string to lowercase.
<b>Declared In</b>	StringMgr.h
<b>Prototype</b>	Char *StrToLower (Char *dst, const Char *src)
<b>Parameters</b>	-> dst                    Pointer to a string.

## String Manager

### String Manager Functions

---

-> `src`                      Pointer to a null-terminated string.

**Result**                      Returns a pointer to the destination string.

**Compatibility**              Prior to Palm OS version 3.5, this function only converted accented characters on Japanese devices. On Palm OS version 3.5 and higher, all characters are appropriately lowercased, including accented characters on Latin devices.

## StrVPrintF

**Purpose**                      Implements a subset of the ANSI C `vsprintf` call, which writes formatted output to a string.

**Declared In**                 `StringMgr.h`

**Prototype**                 `Int16 StrVPrintF (Char *s, const Char *formatStr, va_list arg)`

**Parameters**                <- `s`                              Pointer to a string into which the results are written. This string is always terminated by a null terminator.

-> `formatStr`                 Pointer to the format specification string.

-> `arg`                         Pointer to a list of zero or more parameters to be formatted as specified by the `formatStr` string.

**Result**                      Number of characters written to destination string, not including the null terminator. Returns a negative number if there is an error.

**Comments**                 Like the C `vsprintf` function, this function is designed to be called by your own function that takes a variable number of arguments and passes them to this function. For details on how to use it, see [“Using the StrVPrintF Function”](#) on page 267 of the *Palm OS Programmer’s Companion*, vol. I, or refer to `vsprintf` in a standard C reference book.

Currently, only the conversion specifications %d, %i, %u, %x, %s, and %c are implemented by `StrVPrintf` (and related functions). Optional modifiers that are supported include: +, -, <space>, \*, <digits>, h and l (long). Following is a brief description of how these format specifications work (see a C book for more details).

Each conversion specification begins with the % character. Following the % character, there may be one or more of the characters list in [Table 47.1](#), in sequence.

**Table 47.1 StrVPrintf Format Specification**

Character	Description
+	Specifies that a sign always be placed before a number produced by a signed conversion. A + overrides a space if both are used. Example: <code>StrPrintf(s, "%+d %+d", 4, -5);</code> Output to s: +4 -5
-	Specifies that the printed value is left justified within the field width allowed for it. Example: <code>StrPrintf(s, "%5d%-5d%d", 6, 9, 8);</code> Output to s: 69 8
<space>	Specifies that a minus sign always be placed before a negative number and a space before a positive number. Example: <code>StrPrintf(s, "% d % d", 4, -5);</code> Output to s: 4 -5

## String Manager

### String Manager Functions

---

**Table 47.1 StrVPrintf Format Specification (*continued*)**

Character	Description
*	Indicates that the next argument (must be an integer) in the list specifies the field width. In this case, the argument following that one is used for the value of this field. Example: <code>StrPrintf(s, "%*d%d", 4, 8, 5);</code> Output to s: 8 5
<number>	Specifies a minimum field width. If the converted value has fewer characters than the field width, it will be padded with spaces on the left (or right, if the left justified flag is also specified) to fill out the field width. Example: <code>StrPrintf(s, "%d%5d", 4, 3);</code> Output to s: 4 3
h	Specifies that the following d, i, u, or x conversion corresponds to a short or unsigned short argument. Example: <code>StrPrintf(s, "%hd", 401);</code> Output to s: 401
l or L	Specifies that the following d, i, u, x, or c conversion corresponds to a long or unsigned long <code>StrPrintf(s, "%ld", 999999999);</code> Output to s: 999999999
<character>	A character that indicates the type of conversion to be performed. The supported conversion characters include:

**Table 47.1 StrVPrintf Format Specification (continued)**

Character	Description
d or i	A signed integer argument is converted to decimal notation. Example: <code>StrPrintf(s, "%d %d", 4, -4);</code> Output to s: 4     -4
u	An unsigned integer argument is converted to decimal notation. Example: <code>StrPrintf(s, "%u %u", 4, -4);</code> Output to s: 4     65532
x	An integer argument is converted to hexadecimal notation. Example: <code>StrPrintf(s, "%x", 125);</code> Output to s: 0000007D
s	A string ( <code>char *</code> ) argument is copied to the destination string. Example: <code>StrPrintf(s, "ABC%s", "DEF");</code> Output to s: ABCDEF
c or C	A single character argument is copied to the destination string. If C is used or if the l modifier is used, the argument must be a <code>WChar</code> . Example: <code>StrPrintf(s, "Telephone%c", 's');</code> Output to s: Telephones
%	A % character is copied to the destination string. Example: <code>StrPrintf(s, "%%");</code> Output to s: %

**Example** Here's an example of how to use this call:

## String Manager

### *String Manager Functions*

---

```
#include <unix_stdarg.h>
void MyPrintf(Char *s, Char *formatStr, ...)
{
    va_list args;
    Char text[0x100];
    va_start(args, formatStr);
    StrVPrintf(text, formatStr, args);
    va_end(args);
    MyPutS(text);
}
```

**Compatibility**    Implemented only if [2.0 New Feature Set](#) is present.

**See Also**        [StrPrintf](#)

# System Event Manager

---

This chapter describes functions available in the system event manager. The system event manager API is declared in the header files `Event.h` and `SysEvtMgr.h`.

For more information on the system event manager, see the chapter “[Event Loop](#)” in the *Palm OS Programmer’s Companion*, vol. I. The reference for specific events sent by the system are documented in “[Palm OS Events](#).”

## System Event Manager Data Structures

The following system event manager data structures are documented in the “Palm OS Events” chapter:

- [eventsEnum](#)
- [EventType](#)
- [EventPtr](#)

## System Event Manager Functions

### **EvtAddEventToQueue**

- Purpose** Add an event to the event queue.
- Declared In** `Event.h`
- Prototype** `void EvtAddEventToQueue (const EventType *event)`
- Parameters** `-> event` Pointer to the structure that contains the event.
- Result** Returns nothing.
- Comments** This function makes a copy of the structure that you pass in and adds it to the event queue.

### **EvtAddUniqueEventToQueue**

- Purpose** Add an event to the event queue, replacing one of the same type if it is found.
- Declared In** `Event.h`
- Prototype** `void EvtAddUniqueEventToQueue (const EventType *eventP, UInt32 id, Boolean inplace)`
- Parameters** `-> eventP` Pointer to the structure that contains the event.
- `-> id` ID of the event. 0 means match only on the type.
- `-> inplace` If true, any existing event is replaced. If false, the existing event is deleted and a new event is added to end of queue.
- Result** Returns nothing.

**Comments** This function looks for an event in the event queue of the same event type and ID (if specified). The routine replaces it with the new event, if found.

If no existing event is found, the new event is copied to the queue.

If an existing event is found, the routine proceeds as follows:

- If `inPlace` is `true`, the existing event is replaced with a copy of the new event.
- If `inPlace` is `false`, the existing event is removed and the new event is added to the end of the queue.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## **EvtCopyEvent**

<b>Purpose</b>	Copy an event.				
<b>Declared In</b>	Event.h				
<b>Prototype</b>	<code>void EvtCopyEvent (const EventType *source, EventType *dest)</code>				
<b>Parameters</b>	<table><tr><td>-&gt; source</td><td>Pointer to the structure containing the event to copy.</td></tr><tr><td>&lt;- dest</td><td>Pointer to the structure to copy the event to.</td></tr></table>	-> source	Pointer to the structure containing the event to copy.	<- dest	Pointer to the structure to copy the event to.
-> source	Pointer to the structure containing the event to copy.				
<- dest	Pointer to the structure to copy the event to.				
<b>Result</b>	Returns nothing.				
<b>Comments</b>	<p>Use this function only if you want to create an event that has the same type as the source event. The data field in an <a href="#">EventType</a> structure is specific to events of a given type. If you were to use this function to copy a <a href="#">keyDownEvent</a> and then change it to a <a href="#">frmLoadEvent</a>, the resulting frmLoadEvent would not have the proper data field.</p> <p>If you want to create an event of a different type, do not use EvtCopyEvent. First clear the EventType structure using <a href="#">MemSet</a> and then change the event type:</p> <pre>MemSet (&amp;event, sizeof (EventType), 0); event.eType = frmLoadEvent; event.data.frmLoad.formID = formID; EvtAddEventToQueue (&amp;event);</pre>				

## **EvtDequeuePenPoint**

<b>Purpose</b>	Get the next pen point out of the pen queue. This function is called by recognizers.
<b>Declared In</b>	<code>SysEvtMgr.h</code>
<b>Prototype</b>	<code>Err EvtDequeuePenPoint (PointType *retP)</code>
<b>Parameters</b>	<code>&lt;- retP</code> Return point.
<b>Result</b>	Always returns 0.
<b>Comments</b>	Called by a recognizer that wishes to extract the points of a stroke. Returns the point (-1, -1) at the end of a stroke.  Before calling this routine, you must call <a href="#">EvtDequeuePenStrokeInfo</a> .

## **EvtDequeuePenStrokeInfo**

<b>Purpose</b>	Initiate the extraction of a stroke from the pen queue.
<b>Declared In</b>	<code>SysEvtMgr.h</code>
<b>Prototype</b>	<code>Err EvtDequeuePenStrokeInfo (PointType *startPtP, PointType *endPtP)</code>
<b>Parameters</b>	<code>&lt;- startPtP</code> Start point returned here. <code>&lt;- endPtP</code> End point returned here.
<b>Result</b>	Always returns 0.
<b>Comments</b>	Called by the system function <code>EvtGetSysEvent</code> when a <a href="#">penUpEvent</a> is being generated. This routine must be called before <a href="#">EvtDequeuePenPoint</a> is called.  Subsequent calls to <code>EvtDequeuePenPoint</code> return points at the starting point in the stroke and including the end point. After the

## System Event Manager

### System Event Manager Functions

---

end point is returned, the next call to [EvtDequeuePenPoint](#) returns the point -1, -1.

**See Also** [EvtDequeuePenPoint](#)

## EvtEnableGraffiti

**Purpose** Set Graffiti® enabled or disabled.

**Declared In** SysEvtMgr.h

**Prototype** void EvtEnableGraffiti (Boolean enable)

**Parameters** -> enable true to enable Graffiti, false to disable Graffiti.

**Result** Returns nothing.

## EvtEnqueueKey

**Purpose** Place keys into the key queue.

**Declared In** SysEvtMgr.h

**Prototype** Err EvtEnqueueKey (WChar ascii, UInt16 keycode, UInt16 modifiers)

**Parameters**

- > ascii Character code for the key.
- > keycode Virtual key code of key. This is the keyCode field of the [keyDownEvent](#) and is currently unused.
- > modifiers Modifiers for keyDownEvent.

**Result** Returns 0 if successful, or evtErrParamErr if an error occurs.

**Comments** This function disables interrupts while the queue header is being modified because both interrupt- and non-interrupt-level code can post keys into the queue.

Entries in the key queue only take 1 byte if the `ascii` parameter has a value less than 256 and the `keycode` and `modifiers` parameters are both zero. Otherwise an entry can take up to 7 bytes.

---

**IMPORTANT:** Make sure you pass a `wChar` as the `ascii` parameter, not a `Char`. If you pass a high-ASCII `Char`, the compiler sign-extends it to be a 16-bit value, resulting in the wrong character being added to the key queue.

---

## **EvtEventAvail**

**Purpose** Return `true` if an event is available.

**Declared In** `Event.h`

**Prototype** `Boolean EvtEventAvail (void)`

**Parameters** None.

**Result** Returns `true` if an event is available, `false` otherwise.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## **EvtFlushKeyQueue**

- Purpose** Flush all keys out of the key queue.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtFlushKeyQueue (void)`
- Parameters** None.
- Result** Always returns 0.
- Comments** Called by the system function `EvtSetPenQueuePtr`.

## **EvtFlushNextPenStroke**

- Purpose** Flush the next stroke out of the pen queue.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtFlushNextPenStroke ()`
- Parameters** None.
- Result** Always returns 0.
- Comments** Called by recognizers that need only the start and end points of a stroke. If a stroke has already been partially dequeued (by [EvtDequeuePenStrokeInfo](#)) this routine finishes the stroke dequeuing. Otherwise, this routine flushes the next stroke in the queue.
- See Also** [EvtDequeuePenPoint](#)

## EvtFlushPenQueue

<b>Purpose</b>	Flush all points out of the pen queue.
<b>Declared In</b>	<code>SysEvtMgr.h</code>
<b>Prototype</b>	<code>Err EvtFlushPenQueue (void)</code>
<b>Parameters</b>	None
<b>Result</b>	Always returns 0.
<b>Comments</b>	Called by the system function <code>EvtSetKeyQueuePtr</code> .
<b>See Also</b>	<a href="#">EvtPenQueueSize</a>

## EvtGetEvent

<b>Purpose</b>	Return the next available event.				
<b>Declared In</b>	<code>Event.h</code>				
<b>Prototype</b>	<code>void EvtGetEvent (EventType *event, Int32 timeout)</code>				
<b>Parameters</b>	<table><tr><td><code>&lt;- event</code></td><td>Pointer to the structure to hold the event returned.</td></tr><tr><td><code>-&gt; timeout</code></td><td>Maximum number of ticks to wait before an event is returned (<code>evtWaitForever</code> means wait indefinitely).</td></tr></table>	<code>&lt;- event</code>	Pointer to the structure to hold the event returned.	<code>-&gt; timeout</code>	Maximum number of ticks to wait before an event is returned ( <code>evtWaitForever</code> means wait indefinitely).
<code>&lt;- event</code>	Pointer to the structure to hold the event returned.				
<code>-&gt; timeout</code>	Maximum number of ticks to wait before an event is returned ( <code>evtWaitForever</code> means wait indefinitely).				
<b>Comments</b>	<p>Pass <code>evtWaitForever</code> as the timeout in most instances. When running on the device, this makes the CPU go into doze mode until the user provides input. For applications that do animation, pass a timeout value greater than or equal to zero.</p> <p>Note that a timeout value greater than or equal to zero is simply the <i>maximum</i> number of ticks which can elapse before <code>EvtGetEvent</code> returns an event. If any other event—including a <code>nilEvent</code>—</p>				

## System Event Manager

### System Event Manager Functions

---

occurs before this time has elapsed, `EvtGetEvent` will return that event. Otherwise, once the specified time has elapsed `EvtGetEvent` generates and returns a `nilEvent`. If you supply a value of zero for the timeout parameter, `EvtGetEvent` returns the event currently in the queue, or, if there aren't any events in the queue, it immediately generates and returns a `nilEvent`.

**Result** Returns nothing.

## EvtGetPen

**Purpose** Return the current status of the pen.

**Declared In** `Event.h`

**Prototype** `void EvtGetPen (Int16 *pScreenX, Int16 *pScreenY, Boolean *pPenDown)`

**Parameters**

<- pScreenX	x location relative to display.
<- pScreenY	y location relative to display.
<- pPenDown	true or false.

**Result** Returns nothing.

**Comments** Called by various UI routines.

**See Also** [EvtGetPenNative](#), [KeyCurrentState](#)

## EvtGetPenBtnList

- Purpose** Return a pointer to the silk-screen button array.
- Declared In** SysEvtMgr.h
- Prototype** `const PenBtnInfoType *EvtGetPenBtnList  
(UInt16 *numButtons)`
- Parameters** <- numButtons The number of elements in the returned array.
- Result** Returns a pointer to an array of the silk-screen buttons.
- Comments** This function returns an array of PenBtnInfoType structures:

```
typedef struct PenBtnInfoType {  
    RectangleType boundsR;  
    WChar          asciiCode;  
    UInt16         keyCode;  
    UInt16         modifiers;  
} PenBtnInfoType;
```

The fields in the PenBtnInfoType contain the following information:

- boundsR The button's bounding rectangle.
- asciiCode The character code generated when the button is tapped. This is typically a virtual character.
- keyCode Currently unused.
- modifiers Modifiers for the key down event. (See the description of the modifiers field for [keyDownEvent](#).)

The number of buttons is device-dependent. Even devices with the same Palm OS® version may have differing numbers of silk-screen buttons. For example, Japanese devices typically have four extra

## System Event Manager

### System Event Manager Functions

---

silk-screen buttons used to transliterate characters into different alphabets.

**See Also** [EvtProcessSoftKeyStroke](#)

---

## **New** EvtGetPenNative

**Purpose** Get the current status of the pen using a window's active coordinate system.

**Declared In** Window.h

**Prototype** void EvtGetPenNative (WinHandle winH,  
Int16 \*pScreenX, Int16 \*pScreenY,  
Boolean \*pPenDown)

**Parameters**

-> winH	Handle to a valid window.
<- pScreenX	x location relative to the window.
<- pScreenY	y location relative to the window.
<- pPenDown	true if the pen is down, false otherwise.

**Result** Returns nothing.

**Comments** This function is a variation on [EvtGetPen](#). EvtGetPen returns a pen sample using the standard coordinate system, relative to the draw window, whereas EvtGetPenNative returns a pen sample using the active coordinate system of winH, relative to the window origin. If the active coordinate system is high density, the returned pen sample uses high-density coordinates.

On a debug ROM this function displays an error if winH doesn't reference a valid window object.

**Compatibility** Implemented only if the [High-Density Display Feature Set](#) is present.

## **EvtGetSilkscreenAreaList**

- Purpose** Returns a pointer to the silk-screen area array. This array contains the bounds of each silk-screen area.
- Declared In** `SysEvtMgr.h`
- Prototype** `const SilkscreenAreaType  
*EvtGetSilkscreenAreaList (UInt16 *numAreas)`
- Parameters** `<- numAreas` The number of elements in the returned array.
- Result** Returns a pointer to an array containing the bounds of each silk-screen area.
- Comments** This function returns an array of the `SilkscreenAreaType` structures:
- ```
typedef struct SilkscreenAreaType {  
    RectangleType bounds;  
    UInt32      areaType;  
    UInt16      index;  
} SilkscreenAreaType;
```
- The fields in this structure provide the following information.
- `bounds` The area's bounds.

## System Event Manager

### System Event Manager Functions

---

**areaType** The area type, can be one of the following:

- `silkscreenRectGraffiti`  
The Graffiti area.
- `silkscreenRectScreen`  
The entire silkscreen area.

Depending on the handheld manufacturer, Palm Powered™ devices may have other area types.

**index** If the area type is `silkscreenRectGraffiti`, this field is either `alphaGraffitiSilkscreenArea` to represent the portion where letters are entered or `numericGraffitiSilkscreenArea` to represent the portion where numbers are entered.

**Compatibility** Implemented only if [3.5 New Feature Set](#) is present. If [5.0 New Feature Set](#) is present, this function should be considered “System Use Only”; applications should do what they can to avoid using it.

## EvtKeyDownIsVirtual

**Purpose** Macro that indicates if `eventP` is a pointer to a virtual character key down event.

**Declared In** `Event.h`

**Prototype** `EvtKeyDownIsVirtual (eventP)`

**Parameters** `-> eventP` Pointer to an [EventType](#) structure.

**Result** Returns `true` if the character is a letter in an alphabet or a numeric digit, `false` otherwise.

**Comments** The macro assumes that the caller has already determined the event is a `keyDownEvent`.

This macro is intended for use by the system. Applications should use [TxtGlueCharIsVirtual](#), contained in the [PalmOSGlue Library](#).

**Compatibility**    Implemented in the Palm OS 3.5 SDK.

**See Also**        [TxtGlueCharIsVirtual](#)

## **EvtKeyQueueEmpty**

**Purpose**            Return `true` if the key queue is currently empty.

**Declared In**      `SysEvtMgr.h`

**Prototype**        `Boolean EvtKeyQueueEmpty (void)`

**Parameters**      None.

**Result**            Returns `true` if the key queue is currently empty, otherwise returns `false`.

**Comments**        Usually called by the key manager to determine if it should enqueue auto-repeat keys.

## **EvtKeyQueueSize**

**Purpose**            Return the size of the current key queue in bytes.

**Declared In**      `SysEvtMgr.h`

**Prototype**        `UInt32 EvtKeyQueueSize (void)`

**Parameters**      None.

**Result**            Returns size of queue in bytes.

**Comments**        Called by applications that wish to see how large the current key queue is.

## **EvtPenQueueSize**

- Purpose** Return the size of the current pen queue in bytes.
- Declared In** `SysEvtMgr.h`
- Prototype** `UInt32 EvtPenQueueSize (void)`
- Parameters** None.
- Result** Returns size of queue in bytes.
- Comments** Call this function to see how large the current pen queue is.

## **EvtProcessSoftKeyStroke**

- Purpose** Translate a stroke in the system area of the digitizer and enqueue the appropriate key events in to the key queue.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtProcessSoftKeyStroke (PointType *startPtP, PointType *endPtP)`
- Parameters**
- > `startPtP` Start point of stroke.
  - > `endPtP` End point of stroke.
- Result** Returns 0 if recognized, -1 if not recognized.
- See Also** [EvtGetPenBtnList](#), [GrfProcessStroke](#)

## **EvtResetAutoOffTimer**

- Purpose** Reset the auto-off timer.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtResetAutoOffTimer (void)`
- Parameters** None.
- Result** Always returns 0.
- Comments** Called by the serial link manager; can be called periodically by other managers.
- `EvtResetAutoOffTimer` resets the auto-off timer so that the device does not turn off until at least the default amount of idle time has passed. You can use this function to ensure that the device doesn't automatically power off during a long operation without user input (for example, when there is a lot of serial port activity).
- If you need more control over the auto-off timer and the [3.5 New Feature Set](#) is present, consider using [EvtSetAutoOffTimer](#) instead of this function.
- See Also** [SysSetAutoOffTime](#)

## **EvtSetAutoOffTimer**

- Purpose** Set the auto-off timer.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtSetAutoOffTimer (EvtSetAutoOffCmd cmd, UInt16 timeout)`
- Parameters** `-> cmd` One of the defined commands.

## System Event Manager

### System Event Manager Functions

---

-> `timeout`      A new timeout value in seconds. If `cmd` is `ResetTimer`, this parameter is ignored.

**Result**      Always returns `errNone`.

**Comments**      Use `EvtSetAutoOffTimer` to ensure that the device doesn't automatically power off during a long operation that has no user input (for example, when there is a lot of serial port activity).

The `cmd` parameter specifies the operation you want to perform. It takes one of the following `EvtSetAutoOffCmd` constants:

`SetAtLeast`      Make sure that the device won't turn off until `timeout` seconds of idle time has passed. (This operation only changes the current value if it's less than the value you specify.)

`SetExactly`      Set the timer to turn off in `timeout` seconds

`SetAtMost`      Make sure the device will turn before `timeout` seconds has passed. (This operation only changes the current value if it's greater than the value you specify.)

`SetDefault`      Change the default auto-off timeout to `timeout` seconds.

`ResetTimer`      Reset the auto-off timer so that the device does not turn off until at least the default seconds of idle time has passed.

**Compatibility**      Implemented only if [3.5 New Feature Set](#) is present.

**See Also**      [EvtResetAutoOffTimer](#), [SysSetAutoOffTime](#)

## EvtSetNullEventTick

|                      |                                                                                                                                 |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Make sure a <a href="#">nilEvent</a> occurs in at least the specified number of ticks.                                          |
| <b>Declared In</b>   | <code>SysEvtMgr.h</code>                                                                                                        |
| <b>Prototype</b>     | <code>Boolean EvtSetNullEventTick(UInt32 tick)</code>                                                                           |
| <b>Parameters</b>    | <code>-&gt; tick</code> Maximum number of system ticks that should elapse before a <code>nilEvent</code> is added to the queue. |
| <b>Result</b>        | Returns <code>true</code> if timeout value changed, or <code>false</code> if it did not change.                                 |
| <b>Compatibility</b> | In versions prior to Palm OS 3.5, this function was implemented as a macro.                                                     |

## EvtSysEventAvail

|                      |                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return <code>true</code> if a low-level system event (such as a pen or key event) is available.                                                |
| <b>Declared In</b>   | <code>SysEvtMgr.h</code>                                                                                                                       |
| <b>Prototype</b>     | <code>Boolean EvtSysEventAvail (Boolean ignorePenUps)</code>                                                                                   |
| <b>Parameters</b>    | <code>ignorePenUps</code> If <code>true</code> , this routine ignores pen-up events when determining if there are any system events available. |
| <b>Result</b>        | Returns <code>true</code> if a system event is available.                                                                                      |
| <b>Comment</b>       | Call <a href="#">EvtEventAvail</a> to determine whether high-level software events are available.                                              |
| <b>Compatibility</b> | Implemented only if <a href="#">2.0 New Feature Set</a> is present.                                                                            |

## System Event Manager

### System Event Manager Functions

---

#### EvtWakeup

- Purpose** Force the event manager to wake up and send a [nilEvent](#) to the current application.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtWakeup (void)`
- Parameters** None.
- Result** Always returns 0.
- Comments** Called by interrupt routines, like the sound manager and alarm manager.
- See Also** [EvtWakeupWithoutNilEvent](#)

#### EvtWakeupWithoutNilEvent

- Purpose** Force the event manager to wake up without sending a `nilEvent` to the current application.
- Declared In** `SysEvtMgr.h`
- Prototype** `Err EvtWakeupWithoutNilEvent ()`
- Parameters** None.
- Result** Always returns 0.
- Comments** Called by interrupt routines.
- Compatibility** Implemented only if [4.0 New Feature Set](#) is present.
- See Also** [EvtWakeup](#)

# System Manager

---

This chapter provides reference material for the system manager. The system manager API is declared in the header files `SystemMgr.h` and `SysUtils.h`.

For more information on the system manager, see the chapters “[Application Startup and Stop](#)” and “[Palm System Support](#)” in the *Palm OS Programmer’s Companion*, vol. I.

## System Manager Data Structures

### SysDBListItemType

The `SysDBListItemType` structure describes a single database or panel. The [SysCreateDataBaseList](#) and [SysCreatePanelList](#) functions each create and return an array of `SysDBListItemType` structures.

```
typedef struct {
    Char          name [dmDBNameLength] ;
    UInt32        creator;
    UInt32        type;
    UInt16        version;
    LocalID       dbID;
    UInt16        cardNo;
    BitmapPtr     iconP;
} SysDBListItemType;
```

## System Functions

### SysAppLaunch

- Purpose** Launch a specified application as a subroutine of the caller.
- Declared In** `SystemMgr.h`
- Prototype** `Err SysAppLaunch (UInt16 cardNo, LocalID dbID, UInt16 launchFlags, UInt16 cmd, MemPtr cmdPBP, UInt32 *resultP)`
- Parameters**
- > `cardNo, dbID` The card number and ID of the resource database of the application to launch.
  - > `launchFlags` Set to 0.
  - > `cmd` Launch code.
  - > `cmdPBP` Launch code parameter block.
  - <- `resultP` The value returned from the application's [PilotMain](#) routine.
- Result** Returns 0 if no error, or one of `sysErrParamErr`, `memErrNotEnoughSpace`, or `sysErrOutOfOwnerIDs`.
- Comments** Applications can use `SysAppLaunch` to send a specific launch code to another application and have control return to the calling application when finished. This function in effect makes the specified application a subroutine of the caller. If you want to actually close your application and call another application, use [SysUIAppSwitch](#) instead of this function. `SysUIAppSwitch` sends the current application an `appStopEvent` and then starts the specified application.
- Do not use this function to open the system-supplied Application Launcher application. If another application has replaced the default launcher with one of its own, this function will open the custom launcher instead of the system-supplied one. To open the system-supplied launcher reliably, enqueue a `keyDownEvent` that

contains a `launchChr`, as shown in the section “[Application Launcher](#)” of the user interface chapter in the *Palm OS Programmer’s Companion*, vol. I.

---

**NOTE:** For important information regarding the correct use of this function, see the “[Application Startup and Stop](#)” chapter in the *Palm OS Programmer’s Companion*, vol. I.

---

**See Also** [SysBroadcastActionCode](#), [SysUIAppSwitch](#), [SysCurAppDatabase](#)

## SysBatteryInfo

**Purpose** Retrieve settings for the batteries. Set `set` to `false` to retrieve battery settings. (Applications should **not** change any of the settings).

---

**WARNING!** Use this function only to **retrieve** settings!

---

**Declared In** `SystemMgr.h`

**Prototype** `UInt16 SysBatteryInfo (Boolean set, UInt16 *warnThresholdP, UInt16 *criticalThresholdP, Int16 *maxTicksP, SysBatteryKind *kindP, Boolean *pluggedIn, UInt8 *percentP)`

**Parameters**

|                                 |                                                                                                                          |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>set</code>                | If <code>false</code> , parameters with non-NULL pointers are retrieved. Never set this parameter to <code>true</code> . |
| <code>warnThresholdP</code>     | Pointer to battery voltage warning threshold in volts*100, or NULL.                                                      |
| <code>criticalThresholdP</code> | Pointer to the battery voltage critical threshold in volts*100, or NULL.                                                 |
| <code>maxTicksP</code>          | Pointer to the battery timeout, or NULL.                                                                                 |

## System Manager

### System Functions

---

|                        |                                                          |
|------------------------|----------------------------------------------------------|
| <code>kindP</code>     | Pointer to the battery kind, or NULL.                    |
| <code>pluggedIn</code> | Pointer to <code>pluggedIn</code> return value, or NULL. |
| <code>percentP</code>  | Percentage of power remaining in the battery.            |

**Result** Returns the current battery voltage in volts\*100.

**Comments** Call this function to make sure an upcoming activity won't be interrupted by a low battery warning.

`warnThresholdP` and `maxTicksP` are the battery-warning voltage threshold and time out. If the battery voltage falls below the threshold, or the timeout expires, a `lowBatteryChr` key event is put on the queue. Normally, applications call [SysHandleEvent](#) which calls `SysBatteryDialog` in response to this event.

`criticalThresholdP` is the battery voltage threshold. If battery voltage falls below this level, the system turns itself off without warning and doesn't turn on until battery voltage is above it again.

**Compatibility** This function was revised for Palm OS® 3.0. In Palm OS 3.0, the `percentP` parameter was added. This enhancement is implemented only if [3.0 New Feature Set](#) is present.

**See Also** [SysBatteryInfoV20](#)

## SysBatteryInfoV20

**Purpose** Retrieve settings for the batteries. Set to `false` to retrieve battery settings. (Applications should **not** change any of the settings).

---

**WARNING!** Use this function only to **retrieve** settings!

---

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |     |                                                                                              |                |                                                                     |                    |                                                                          |           |                                          |       |                                       |           |                                             |

| <b>Result</b>        | Returns the current battery voltage in volts*100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |     |                                                                                              |                |                                                                     |                    |                                                                          |           |                                          |       |                                       |           |                                             |
| <b>Comments</b>      | <p>Call this function to make sure an upcoming activity won't be interrupted by a low battery warning.</p> <p>warnThresholdP and maxTicksP are the battery-warning voltage threshold and time out. If the battery voltage falls below the threshold, or the timeout expires, a lowBatteryChr key event is put on the queue. Normally, applications call <a href="#">SysHandleEvent</a> which calls SysBatteryDialog in response to this event.</p> <p>criticalThresholdP is the battery voltage threshold. If battery voltage falls below this level, the system turns itself off without warning and doesn't turn on until battery voltage is above it again.</p> |     |                                                                                              |                |                                                                     |                    |                                                                          |           |                                          |       |                                       |           |                                             |
| <b>Compatibility</b> | This function corresponds to the Palm OS 2.0 version of SysBatteryInfo. Implemented only if <a href="#">3.0 New Feature Set</a> is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |     |                                                                                              |                |                                                                     |                    |                                                                          |           |                                          |       |                                       |           |                                             |
| <b>See Also</b>      | <a href="#">SysBatteryInfo</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |     |                                                                                              |                |                                                                     |                    |                                                                          |           |                                          |       |                                       |           |                                             |

### **SysBinarySearch**

**Purpose** Search elements in a sorted array for the specified data according to the specified comparison function.

**Declared In** `SysUtils.h`

**Prototype** `Boolean SysBinarySearch (void const *baseP,  
Int16 numOfElements, Int16 width,  
SearchFuncPtr searchF, void const *searchData,  
Int32 other, Int32 *position, Boolean findFirst)`

|                   |                            |                                                                                                                                                                                                |
|-------------------|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <code>baseP</code>         | Base pointer to an array of elements                                                                                                                                                           |
|                   | <code>numOfElements</code> | Number of elements to search. Must be greater than 0.                                                                                                                                          |
|                   | <code>width</code>         | Width of each array element.                                                                                                                                                                   |
|                   | <code>searchF</code>       | Search function.                                                                                                                                                                               |
|                   | <code>searchData</code>    | Data to search for. This data is passed to the <code>searchF</code> function.                                                                                                                  |
|                   | <code>other</code>         | Data to be passed as the third parameter (the <code>other</code> parameter) to the comparison function.                                                                                        |
|                   | <code>position</code>      | Pointer to the position result.                                                                                                                                                                |
|                   | <code>findFirst</code>     | If set to <code>true</code> , the first matching element is returned. Use this parameter if the array contains duplicate entries to ensure that the first such entry will be the one returned. |

**Result** Returns `true` if an exact match was found. In this case, `position` points to the element number where the data was found.

Returns `false` if an exact match was not found. If `false` is returned, `position` points to the element number where the data should be inserted if it was to be added to the array in sorted order.

**Comments** The array must be sorted in ascending order prior to the search. Use [SysInsertionSort](#) or [SysQSort](#) to sort the array.

The search starts at element 0 and ends at element (`numOfElements - 1`).

The search function's (`searchF`) prototype is:

```
Int16 _searchF (void const *searchData,  
               void const *arrayData, Int32 other);
```

The first parameter is the data for which to search, the second parameter is a pointer to an element in the array, and the third parameter is any other necessary data.

## System Manager

### System Functions

---

The function returns:

- > 0 if the search data is greater than the element
- < 0 if the search data is less than the element
- 0 if the search data is the same as the element

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysBroadcastActionCode

**Purpose** Send the specified action code (launch code) and parameter block to the latest version of every UI application.

**Declared In** `SystemMgr.h`

**Prototype** `Err SysBroadcastActionCode (UInt16 cmd, MemPtr cmdPBP)`

**Parameters**

|                     |                                      |
|---------------------|--------------------------------------|
| <code>cmd</code>    | Action code to send.                 |
| <code>cmdPBP</code> | Action code parameter block to send. |

**Result** Returns 0 if no error, or one of the following errors: `sysErrParamErr`, `memErrNotEnoughSpace`, or `sysErrOutOfOwnerIDs`.

**See Also** [SysAppLaunch, Chapter 2, "Application Startup and Stop."](#) of the *Palm OS Programmer's Companion*, vol. I

## **SysCopyStringResource**

- Purpose** Copy a resource string to a passed string.
- Declared In** `SysUtils.h`
- Prototype** `void SysCopyStringResource (Char *string,  
Int16 theID)`
- Parameters**
- |                     |                                        |
|---------------------|----------------------------------------|
| <code>string</code> | String to copy the resource string to. |
| <code>theID</code>  | Resource string ID.                    |
- Result** Stores a copy of the resource string in `string`.

## **SysCreateDataBaseList**

**Purpose** Generate a list of databases found on the memory cards matching a specific type and return the result. If `lookupName` is `true` then a name in a `tAIN` resource is used instead of the database's name and the list is sorted. Only the last version of a database is returned. Databases with multiple versions are listed only once.

**Declared In** `SystemMgr.h`

**Prototype** `Boolean SysCreateDataBaseList (UInt32 type, UInt32 creator, UInt16 *dbCount, MemHandle *dbIDs, Boolean lookupName)`

**Parameters**

|                         |                                                                                                                                                                                                                     |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>type</code>       | The type of database to find. Use 0 to find all databases.                                                                                                                                                          |
| <code>creator</code>    | The creator ID of the database to find. Use 0 to find any creator ID.                                                                                                                                               |
| <code>dbCount</code>    | A pointer to an integer value that is updated by this function to the number of matching databases.                                                                                                                 |
| <code>dbIDs</code>      | A pointer to a handle that gets allocated to contain the database list. Upon return, this references an array of <a href="#">SysDBListItemType</a> structures. See the Comments section below for more information. |
| <code>lookupName</code> | If <code>true</code> , <code>SysCreateDatabaseList</code> uses <code>tAIN</code> names and sorts the list.                                                                                                          |

**Result** Returns `false` if no databases were found, and `true` if any databases were found. The value of `dbCount` is updated to reflect the number of databases that were found. If at least one database is found, `dbIDs` is updated to reference a array of [SysDBListItemType](#) structures; this array contains `dbCount` items.

**Comments** This function creates a list of unique databases, where unique is defined as having a different type and creator ID. Two or more databases with the same type and creator ID are counted as one. Thus, you cannot use `SysCreateDatabaseList` to build a list of databases that share a common type and creator. There are two exceptions to this rule, however. If `type` is 0 or if `creator` is not 0, the code that removes “non-unique” databases isn’t run. It also isn’t run if the type is `sysFileTpqa`, since web-clipping databases all have the same type and creator ID.

If this function returns `true` and the value of `dbCount` is greater than 0, than you can iterate through the list of database items, as shown in [Listing 49.1](#)

#### **Listing 49.1 Using the `SysCreateDatabaseList` function**

---

```
SysDBListItemType      *dbListIDsP;
MemHandle              dbListIDsH;
UInt16                 dbCount = 0;
Boolean                status;
UInt16                 counter;
SysDBListItemType      theItem;

status = SysCreateDatabaseList (sysFileTpqa, 0,
                                &dbCount, &dbListIDsH, false);

if (status == true && dbCount > 0)
{
    dbListIDsP = MemHandleLock (dbListIDsH);
    for (counter = 0; counter < dbCount; counter++)
        if StrCompare (dbListIDsP[counter].name,
                        "MINE") == 0
            // we found my database
            ...
    ...
    MemPtrFree (dbListIDsP);
}
```

---

**NOTE:** It is your responsibility to free the memory allocated by this function for the list of databases.

---

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysCreatePanelList

- Purpose** Generate a list of panels found on the memory cards and return the result. Multiple versions of a panel are listed once.
- Declared In** `SystemMgr.h`
- Prototype** `Boolean SysCreatePanelList (UInt16 *panelCount, MemHandle *panelIDs)`
- Parameters**
- |                         |                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>panelCount</code> | Pointer to set to the number of panels.                                                                                                                     |
| <code>panelIDs</code>   | A pointer to a handle that gets allocated to contain the panel list. Upon return, this references an array of <a href="#">SysDBListItemType</a> structures. |
- Result** Returns `false` if no panels were found, and `true` if any panels were found. The value of `panelCount` is updated to reflect the number of panels that were found. If at least one panel is found, `panelIDs` is updated to reference a array of [SysDBListItemType](#) structures; this array contains `panelCount` items.
- Comments** If this function returns `true` and the value of `panelCount` is greater than 0, then you can iterate through the list of panel items, as shown in [Listing 49.1](#). It is your responsibility to free the memory allocated for the panel list.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysCurAppDatabase

- Purpose** Return the card number and database ID of the current application's resource database.
- Declared In** `SystemMgr.h`
- Prototype** `Err SysCurAppDatabase (UInt16 *cardNoP, LocalID *dbIDP)`
- Parameters**
- |                      |                                     |
|----------------------|-------------------------------------|
| <code>cardNoP</code> | Pointer to the card number; 0 or 1. |
| <code>dbIDP</code>   | Pointer to the database ID.         |
- Result** Returns 0 if no error, or `SysErrParamErr` if an error occurs.
- See Also** [SysAppLaunch](#), [SysUIAppSwitch](#)

## SysErrString

- Purpose** Returns text to describe an error number. This routine looks up the textual description of a system error number in the appropriate List resource and creates a string that can be used to display that error.
- The actual string will be of the form: "<error message> (XXXX)" where XXXX is the hexadecimal error number.
- This routine looks for a resource of type 'tstl' and resource ID of (`err>>8`). It then grabs the string at index (`err & 0x00FF`) out of that resource.
- The first string in the resource is called index #1 by Constructor, NOT #0. For example, an error code of 0x0101 will fetch the first string in the resource.
- Declared In** `SysUtils.h`
- Prototype** `Char *SysErrString (Err err, Char *strP, UInt16 maxLen)`
- Parameters**
- |                  |              |
|------------------|--------------|
| <code>err</code> | Error number |
|------------------|--------------|

## System Manager

### System Functions

---

`strP` Pointer to space to form the string  
`maxLen` Size of `strP` buffer.

**Result** Stores the error number string.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## SysFormPointerArrayToStrings

**Purpose** Form an array of pointers to strings in a block. Useful for setting the items of a list.

**Declared In** `SysUtils.h`

**Prototype** `MemHandle SysFormPointerArrayToStrings (Char *c, Int16 stringCount)`

**Parameters** `c` Pointer to packed block of strings, each terminated by a null character.  
`stringCount` Count of strings in block.

**Result** Unlocked handle to allocated array of pointers to the strings in the passed block. The returned array points to the strings in the passed packed block. Note that you'll need to free the returned handle when you no longer need it.

**See Also** [LstSetListChoices](#)

  
**New**

## **sysFtrNumProcessorIs68K**

**Purpose** Macro that determines whether or not the underlying processor is part of the 68K family.

**Declared In** SystemMgr.h

**Prototype**

```
#define sysFtrNumProcessorIs68K(x)
((x&sysFtrNumProcessor68KIfZero)==0)? true :
false)
```

**Parameters** -> x Processor type obtained from a call to [FtrGet](#).

**Result** Returns true if the underlying processor is a 68K, false otherwise.

**Comments** This macro is typically used in conjunction with [PceNativeCall](#).

---

**Example**

```
UInt32 processorType;

FtrGet(sysFileCSystem, sysFtrNumProcessorID, &processorType);
if (sysFtrNumProcessorIs68K(processorType)) {
    // processor is 68K
} else {
    // processor is not 68K
}
```

---

---

## **New** sysFtrNumProcessorIsARM

- Purpose** Macro that determines whether or not the underlying processor is part of the ARM family.
- Declared In** SystemMgr.h
- Prototype**  

```
#define sysFtrNumProcessorIsARM(x)
(((x&sysFtrNumProcessorARMIIfNotZero)!=0)? true :
false)
```
- Parameters** -> x Processor type obtained from a call to [FtrGet](#).
- Result** Returns true if the underlying processor is an ARM core, false otherwise.
- Comments** This macro is typically used in conjunction with [PceNativeCall](#).

---

### **Example**

```
UInt32 processorType;

FtrGet(sysFileCSystem, sysFtrNumProcessorID, &processorType);
if (sysFtrNumProcessorIsARM(processorType)) {
    // processor is ARM
} else {
    // processor is not ARM
}
```

---

## SysGetOSVersionString

|                      |                                                                                  |
|----------------------|----------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the version number of the Palm™ operating system.                         |
| <b>Declared In</b>   | SystemMgr.h                                                                      |
| <b>Prototype</b>     | Char *SysGetOSVersionString()                                                    |
| <b>Parameters</b>    | None.                                                                            |
| <b>Result</b>        | Returns a string such as “v. 3.0.”                                               |
| <b>Comments</b>      | You must free the returned string using the <a href="#">MemPtrFree</a> function. |
| <b>Compatibility</b> | Implemented only if <a href="#">3.0 New Feature Set</a> is present.              |

## SysGetROMToken

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |           |                                                                                                                                |          |                                                                                                                                                                                 |          |                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|--------------------------------------------------------------------------------------------------------------------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Return from ROM a value specified by token.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |           |                                                                                                                                |          |                                                                                                                                                                                 |          |                                                                                    |

## System Manager

### System Functions

---

`<- sizeP`                      The number of bytes in the `dataP` buffer.

**Result**                      Returns the requested value if no error, or an error code if an error occurs. If this function returns an error, or if the returned pointer to the buffer is `NULL`, or if the first byte of the text buffer is `0xFF`, then no serial number is available.

**Comments**                      The serial number is shown to the user in the Application Launcher, along with a checksum digit you can use to validate input when your users read the ID from their device and type it in or tell it to someone else.

**Compatibility**                      Implemented only if [3.0 New Feature Set](#) is present. Serial numbers are available only on flash ROM-based units.

**See Also**                      “[Retrieving the ROM Serial Number](#)” section in the *Palm OS Programmer’s Companion*, vol. I shows how to retrieve the ROM serial number and calculate its associated checksum.

## SysGetStackInfo

**Purpose**                      Return the start and end of the current thread’s stack.

**Declared In**                      `SystemMgr.h`

**Prototype**                      `Boolean SysGetStackInfo (MemPtr *startPP,  
MemPtr *endPP)`

**Parameters**                      `startPP`                      Upon return, points to the start of the stack.  
`endPP`                      Upon return, points to the end of the stack.

**Result**                      Returns `true` if the stack has not overflowed, that is, the value of the stack overflow address has not been changed. Returns `false` if the stack overflow value has been overwritten, meaning that a stack overflow has occurred.

**Compatibility**                      Implemented only if [3.0 New Feature Set](#) is present.

## SysGetTrapAddress

- Purpose** Return the address of a function given its system trap.
- Declared In** `SystemMgr.h`
- Prototype** `void *SysGetTrapAddress (UInt16 trapNum)`
- Parameters** `-> trapNum` One of the routine selectors defined in `SysTraps.h` (`sysTrap...`) or `CoreTraps.h` on Palm OS version 3.5 and higher.
- Result** Returns the address of the corresponding function. Returns the address of the `sysTrapSysUnimplemented` routine if an invalid routine selector is passed; compare the results of this function to `SysGetTrapAddress(sysTrapSysUnimplemented)` if you need to check for an invalid routine selector.
- Comments** Use this function for performance reasons. You can then use the address it returns to call the function without having to go through the trap dispatch table. This function is mostly useful for optimizing the performance of functions called in a tight loop.
- The Palm OS trap dispatch mechanism allows the trap table entries to be modified at any time, either as the result of a system update or a hack. For this reason, it's important to call this function **immediately before** entering the tight loop. If the trap address changes in between when you call `SysGetTrapAddress` and you use the address, the wrong function will be called.
- Compatibility** On Palm OS 3.0 and earlier, this function contains a bug that causes it to return a garbage value if an invalid routine selector is passed. To prevent this bug from affecting your application, use `SysGlueGetTrapAddress` in the PalmOSGlue library instead of calling this function directly. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

### SysGremlins

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                       |                                                  |                     |                                                                                                           |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|--------------------------------------------------|---------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>        | Query the Gremlins facility. You pass a selector for a function and parameters for that function. Gremlins performs the function call and returns the result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                       |                                                  |                     |                                                                                                           |
| <b>Declared In</b>    | <code>SysUtils.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                       |                                                  |                     |                                                                                                           |

## SysInsertionSort

|                    |                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | Sort elements in an array according to the passed comparison function.                                                                                                                                                                             |
| <b>Declared In</b> | <code>SysUtils.h</code>                                                                                                                                                                                                                            |
| <b>Prototype</b>   | <code>void SysInsertionSort (void *baseP,<br/>Int16 numElements, Int16 width,<br/>CmpFuncPtr comparF, Int32 other)</code>                                                                                                                          |
| <b>Parameters</b>  | <code>baseP</code> Base pointer to an array of elements.<br><code>numElements</code> Number of elements to sort (must be at least 2).<br><code>width</code> Width of an element.<br><code>comparF</code> Comparison function. See Comments, below. |

## System Manager

### *System Functions*

---

other

Other data passed to the comparison function.

**Result** Returns nothing.

**Comments** Only elements which are out of order move. Moved elements are moved to the end of the range of equal elements. If a large amount of elements are being sorted, try to use the quick sort (see [SysQSort](#)).

This is the insertion sort algorithm: Starting with the second element, each element is compared to the preceding element. Each element not greater than the last is inserted into sorted position within those already sorted. A binary search for the insertion point is performed. A moved element is inserted after any other equal elements.

In order to use `SysInsertionSort` you must write a comparison function with the following prototype:

```
Int16 comparF (void *p1, void *p2, Int32 other)
```

Your comparison function must return zero if `p1` equals `p2`, a positive integer value if `p1` is greater than `p2`, and a negative integer value if `p1` is less than `p2`. Note that the value of the parameter named `other` is passed through from the `SysInsertionSort` call and can be used to control the behavior of the `comparF` function if appropriate for your application.

**Compatibility** The Palm OS 2.0 comparison function (`comparF`) has this prototype:

```
Int comparF (VoidPtr, VoidPtr, Long other);
```

The Palm OS 1.0 comparison function (`comparF`) has this prototype:

```
Int comparF (BytePtr A, BytePtr B, Long other);
```

**See Also** [SysQSort](#)

### SysKeyboardDialog

- Purpose** Pop up the system keyboard if there is a field object with the focus. The field object's text chunk is edited directly.
- Declared In** `Keyboard.h`
- Prototype** `void SysKeyboardDialog (KeyboardType kbd)`
- Parameters** `kbd` The keyboard type. See `Keyboard.h`.
- Result** Returns nothing. Changes the field's text chunk.
- Compatibility** Implemented only if [2.0 New Feature Set](#) is present.
- See Also** [SysKeyboardDialogV10](#), [FrmSetFocus](#)

### SysKeyboardDialogV10

- Purpose** Pop up the system keyboard if there is a field object with the focus. The field object's text chunk is edited directly.
- Declared In** `Keyboard.h`
- Prototype** `void SysKeyboardDialogV10 ()`
- Parameters** None.
- Result** Returns nothing. The field's text chunk is changed.
- Compatibility** Corresponds to the 1.0 implementation of `SysKeyboardDialog`.
- See Also** [SysKeyboardDialog](#), [FrmSetFocus](#)

## SysLibFind

|                      |                                                                                                                                                                                                                                                                                                                                                                                                 |                    |                                          |                      |                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|------------------------------------------|----------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return a reference number for a library that is already loaded, given its name.                                                                                                                                                                                                                                                                                                                 |                    |                                          |                      |                                                                                                           |
| <b>Declared In</b>   | <code>SystemMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                        |                    |                                          |                      |                                                                                                           |

| <code>refNumP</code> | Pointer to a variable for returning the library reference number (on failure, this variable is undefined)                                                                                                                                                                                                                                                                                       |                    |                                          |                      |                                                                                                           |
| <b>Result</b>        | 0 if no error; otherwise: <code>sysErrLibNotFound</code> (if the library is not yet loaded), or another error returned from the library's install entry point.                                                                                                                                                                                                                                  |                    |                                          |                      |                                                                                                           |
| <b>Comments</b>      | Most built-in libraries (NetLib, serial, IR) are preloaded automatically when the system is reset. Third-party libraries must be loaded before this call can succeed (use <a href="#">SysLibLoad</a> ). You can check if a library is already loaded by calling <code>SysLibFind</code> and checking for a 0 error return value (it will return a non-zero value if the library is not loaded). |                    |                                          |                      |                                                                                                           |

## SysLibInstall

|                             |                                                                                                              |                             |                                         |
|-----------------------------|--------------------------------------------------------------------------------------------------------------|-----------------------------|-----------------------------------------|
| <b>Purpose</b>              | Installs a library into the Library table and calls the library's install entry point.                       |                             |                                         |
| <b>Declared In</b>          | <code>SystemMgr.h</code>                                                                                     |                             |                                         |
| <b>Prototype</b>            | <code>Err SysLibInstall (SysLibEntryProcPtr libraryP,<br/>UInt16 *refNumP)</code>                            |                             |                                         |
| <b>Parameters</b>           | <table><tr><td><code>-&gt; libraryP</code></td><td>Pointer to the library being installed.</td></tr></table> | <code>-&gt; libraryP</code> | Pointer to the library being installed. |
| <code>-&gt; libraryP</code> | Pointer to the library being installed.                                                                      |                             |                                         |

## System Manager

### System Functions

---

<- refNumP            Pointer to the variable in which the installed library reference number is stored upon return.

**Result**            Returns 0 if no error, memErrNotEnoughSpace if an error occurs while allocating memory in the library table, or, if an error is returned by the call to the library's install entry point, that error is returned and the reference number is set to sysInvalidRefNum.

**Comments**        This routine is largely used by the Palm OS, but can also be called by applications that need to install their own libraries.

**Compatibility**    Implemented only if [2.0 New Feature Set](#) is present.

## SysLibLoad

**Purpose**            Load a library given its database creator and type.

**Declared In**      SystemMgr.h

**Prototype**        Err SysLibLoad (UInt32 libType,  
                  UInt32 libCreator, UInt16 \*refNumP)

**Parameters**      libType            Type of library database.  
                  libCreator        Creator of library database.  
                  refNumP            Pointer to variable for returning the library reference number (on failure, sysInvalidRefNum is returned in this variable)

**Result**            0 if no error; otherwise: sysErrLibNotFound, sysErrNoFreeRAM, sysErrNoFreeLibSlots, or other error returned from the library's install entry point.

**Comments**        Presently, the "load" functionality is **not** supported when you use the Palm OS Simulator.

When an application no longer needs a library that it **successfully** loaded via SysLibLoad, it is responsible for unloading the library

by calling [SysLibRemove](#) and passing it the library reference number returned by [SysLibLoad](#). More information is available in the white paper on shared libraries, which you can find on the Palm developer support web site.

**Compatibility**    Implemented only if [2.0 New Feature Set](#) is present.

## **SysLibRemove**

**Purpose**            Unload a library previously loaded with [SysLibLoad](#).

**Declared In**      `SystemMgr.h`

**Prototype**        `Err SysLibRemove (UInt16 refNum)`

**Parameters**       `-> refNum`            The library reference number.

**Result**            0 if no error; otherwise `sysErrParamErr` if the `refNum` is not a valid library reference number.

**Comments**        `SysLibRemove` releases the dynamic memory allocated to the shared library's dispatch table, resources, and global variables.

## **SysQSort**

**Purpose**            Sort elements in an array according to the supplied comparison function.

**Declared In**      `SysUtils.h`

**Prototype**        `void SysQSort (void *baseP, Int16 numOfElements, Int16 width, CmpFuncPtr comparF, Int32 other)`

**Parameters**       `baseP`                    Base pointer to an array of elements.  
`numOfElements`        Number of elements to sort (must be at least 2).  
`width`                    Width of an element.

## System Manager

### System Functions

---

|                      |                                               |
|----------------------|-----------------------------------------------|
| <code>comparF</code> | Comparison function. See Comments, below.     |
| <code>other</code>   | Other data passed to the comparison function. |

**Result** Returns nothing.

**Comments** Equal records can be in any position relative to each other because a quick sort tends to scramble the ordering of records. As a result, calling `SysQSort` multiple times can result in a different order if the records are not completely unique. If you don't want this behavior, use the insertion sort instead (see [SysInsertionSort](#)).

To pick the pivot point, the quick sort algorithm picks the middle of three records picked from around the middle of all records. That way, the algorithm can take advantage of partially sorted data.

These optimizations are built in:

- The routine contains its own stack to limit uncontrolled recursion. When the stack is full, an insertion sort is used because it doesn't require more stack space.
- An insertion sort is also used when the number of records is low. This avoids the overhead of a quick sort which is noticeable for small numbers of records.
- If the records seem mostly sorted, an insertion sort is performed to move only those few records that need to be moved.

In order to use `SysQSort` you must write a comparison function with the following prototype:

```
Int16 comparF (void *p1, void *p2, Int32 other)
```

Your comparison function must return zero if `p1` equals `p2`, a positive integer value if `p1` is greater than `p2`, and a negative integer value if `p1` is less than `p2`. Note that the value of the parameter named `other` is passed through from the `SysQSort` call and can be used to control the behavior of the `comparF` function if appropriate for your application.

**Compatibility** The Palm OS 2.0 comparison function (`comparF`) has this prototype:

```
Int comparF (VoidPtr, VoidPtr, Long other);
```

The Palm OS 1.0 comparison function (`comparF`) has this prototype:

```
Int comparF (BytePtr A, BytePtr B, Long other);
```

**See Also** [SysInsertionSort](#)

## **SysRandom**

**Purpose** Return a random number anywhere from 0 to `sysRandomMax`.

**Declared In** `SysUtils.h`

**Prototype** `Int16 SysRandom (Int32 newSeed)`

**Parameters** `newSeed` New seed value, or 0 to use existing seed.

**Result** Returns a random number.

## **SysReset**

**Purpose** Perform a soft reset and reinitialize the globals and the dynamic memory heap.

**Declared In** `SystemMgr.h`

**Prototype** `void SysReset (void)`

**Parameters** None.

**Result** No return value.

**Comments** This routine resets the system, reinitializes the globals area and all system managers, and reinitializes the dynamic heap. All database information is preserved. This routine is called when the user presses the hidden reset switch on the device.

## System Manager

### System Functions

---

When running an application using the simulator, this routine looks for two data files that represent the memory of card 0 and card 1. If these are found, the Palm OS memory image is created using them. If they are not found, they are created.

When running an application on the device, this routine simply looks for the memory cards at fixed locations.

### SysSetAutoOffTime

- Purpose** Set the time out value in seconds for auto-power-off. Zero means never power off.
- Declared In** `SystemMgr.h`
- Prototype** `UInt16 SysSetAutoOffTime (UInt16 seconds)`
- Parameters** `seconds` Time out in seconds, or 0 for no time out.
- Result** Returns previous value of time out in seconds.

### SysSetTrapAddress

- Purpose** Set the address of the function corresponding to a system trap.
- Declared In** `SystemMgr.h`
- Prototype** `Err SysSetTrapAddress (UInt16 trapNum, void *procP)`
- Parameters**
- |                            |                                                                                                                                                            |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-&gt; trapNum</code> | One of the routine selectors defined in <code>SysTraps.h</code> ( <code>sysTrap...</code> ) or <code>CoreTraps.h</code> on Palm OS version 3.5 and higher. |
| <code>-&gt; procP</code>   | Pointer to a function that the trap identified by <code>trapNum</code> is to point to.                                                                     |
- Result** Returns 0 if no error, or `SysErrParamErr` if `trapNum` is greater than the number of traps in the trap table.

**Comments** This function is useful for patching a system trap, in combination with [SysGetTrapAddress](#). To patch a system trap in your application, first call `SysGetTrapAddress` to get the trap address and then save this value somewhere. Next use `SysSetTrapAddress` to set the trap address to point to your function. Before your application exits, remove the patch by calling `SysSetTrapAddress` and passing in the original trap address you saved.

---

**WARNING!** If your application patches a system trap using this function, you **must** remove the patch before your application exits. Do **not** use this mechanism to permanently patch system traps as it may cause unpredictable results for the system and other applications.

---

**Compatibility** If [5.0 New Feature Set](#) is present this function is unimplemented.

## SysStringByIndex

**Purpose** Copy a string out of a string list resource by index. String list resources are of type 'tSTL' and contain a list of strings and a prefix string.

ResEdit always displays the items in the list as starting at 1, not 0. Consider this when creating your string list.

**Declared In** `SysUtils.h`

**Prototype** `Char *SysStringByIndex (UInt16 resID, UInt16 index, Char *strP, UInt16 maxLen)`

**Parameters**

|                    |                                      |
|--------------------|--------------------------------------|
| <code>resID</code> | Resource ID of the string list.      |
| <code>index</code> | String to get out of the list.       |
| <code>strP</code>  | Pointer to space to form the string. |

## System Manager

### System Functions

---

maxLen                      Size of strP buffer.

**Result**                      Returns a pointer to the copied string. The string returned from this call will be the prefix string appended with the designated index string. Indices are 0-based; index 0 is the first string in the resource.

**Compatibility**              Implemented only if [2.0 New Feature Set](#) is present.

## SysTaskDelay

**Purpose**                        Put the processor into doze mode for the specified number of ticks.

**Declared In**                 SystemMgr.h

**Prototype**                    Err SysTaskDelay (Int32 delay)

**Parameters**                 delay                          Number of ticks to wait (see [SysTicksPerSecond](#))

**Result**                        Returns 0 if no error.

**See Also**                     [EvtGetEvent](#)

## SysTicksPerSecond

**Purpose**                        Return the number of ticks per second. This routine allows applications to be tolerant of changes to the ticks per second rate in the system.

**Declared In**                 SystemMgr.h

**Prototype**                    UInt16 SysTicksPerSecond (void)

**Parameters**                 None

**Result**                        Returns the number of ticks per second.

**Compatibility** Implemented only if [2.0 New Feature Set](#) is present.

## **SysUIAppSwitch**

**Purpose** Try to make the current UI application quit and then launch the UI application specified by card number and database ID.

**Declared In** SystemMgr.h

**Prototype** Err SysUIAppSwitch (UInt16 cardNo, LocalID dbID, UInt16 cmd, MemPtr cmdPBP)

## System Manager

### System Functions

---

|                   |           |                                                                      |
|-------------------|-----------|----------------------------------------------------------------------|
| <b>Parameters</b> | -> cardNo | Card number for the new application; currently only card 0 is valid. |
|                   | -> dbID   | ID of the new application's resource database.                       |
|                   | -> cmd    | Action code (launch code).                                           |
|                   | -> cmdPBP | Action code (launch code) parameter block.                           |

**Result** Returns 0 if no error.

May display a fatal error message if the `cardNo` parameter is invalid. On debug ROMs, displays a fatal error message if there is no currently running application.

**Comments** Do not use this function to open the system-supplied Application Launcher application. If a third-party launch is installed, you'll likely want to launch that one instead. To do this, enqueue a `keyDownEvent` that contains a `launchChr`, as shown in the section "[Application Launcher](#)" of the user interface chapter in the *Palm OS Programmer's Companion*, vol. I. This will run whatever is run whenever you tap on the Applications icon.

If you are passing a parameter block (the `cmdPBP` parameter), you must set the owner of the parameter block chunk to the operating system. To do this, and for more information, see [MemPtrSetOwner](#). If the parameter block structure contains references by pointer or handle to any other chunks, you also must set the owner of those chunks by using [MemHandleSetOwner](#) or [MemPtrSetOwner](#). If you set the owner of this parameter block properly, the system maintains the parameter block and frees it when the second application quits. If you don't set the owner of the parameter block, the system frees the parameter block as soon as the calling application quits, causing unpredictable results.

**See Also** [SysAppLaunch](#), Chapter 2, "[Application Startup and Stop](#)," in the *Palm OS Programmer's Companion*, vol. I.

## Application-Defined Functions

### PilotMain

|                    |                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>     | The entry point for all Palm OS applications, this function's sole purpose is to receive and respond to launch codes.                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                     |
| <b>Declared In</b> | <code>SystemMgr.h</code>                                                                                                                                                                                                                                                  |                                                                                                                                                                                                                                                                                                                                     |
| <b>Prototype</b>   | <code>UInt32 PilotMain(UInt16 cmd, void *cmdPBP, UInt16 launchFlags)</code>                                                                                                                                                                                               |                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <code>-&gt; cmd</code>                                                                                                                                                                                                                                                    | The launch code to which your application is to respond. See <a href="#">Chapter 1, "Application Launch Codes,"</a> on page 3 for a list of predefined launch codes. You may create additional launch codes; see <a href="#">"Creating Your Own Launch Codes"</a> on page 28 of the <i>Palm OS Programmer's Companion</i> , vol. I. |
|                    | <code>-&gt; cmdPBP</code>                                                                                                                                                                                                                                                 | A pointer to a structure containing any launch-command-specific parameters, or <code>NULL</code> if the launch code has none. See the description of each launch code for a description of the parameter structure that accompanies it, if any.                                                                                     |
|                    | <code>-&gt; launchFlags</code>                                                                                                                                                                                                                                            | Flags that indicate whether your application's global variables are available, whether your application is now the active application, whether it already was the active application, and so on. See <a href="#">"Launch Flags"</a> on page 36 for a list of launch flags.                                                          |
| <b>Result</b>      | Return <code>errNone</code> if your application processed the launch code successfully, or an appropriate error code if there was a problem. When another application invokes your application using <a href="#">SysAppLaunch</a> , this value is returned to the caller. |                                                                                                                                                                                                                                                                                                                                     |

## System Manager

### *Application-Defined Functions*

---

**Comments** See [Chapter 2, “Application Startup and Stop,”](#) on page 19 of the *Palm OS Programmer’s Companion*, vol. I for a discussion on how applications receive and handle launch codes, with examples.

# Text Manager

---

This chapter provides information about the text manager API declared in `TextMgr.h` by discussing these topics:

- [Text Manager Data Structures](#)
- [Text Manager Functions](#)

For more information on the text manager, see the chapter “[Localized Applications](#)” on page 363 in the *Palm OS Programmer’s Companion*, vol. I.

## Text Manager Data Structures

### CharEncodingType

The `CharEncodingType` enum specifies possible character encodings. The [Character Encoding Constants](#) define the possible values for `CharEncodingType` variables.

```
UInt8 CharEncodingType;
```

A given device supports a single character encoding. The currently available devices support either the Palm™ version of Windows code page 1252 (an extension of ISO Latin 1) or the Palm version of Windows code page 932 (an extension of Shift JIS). These encodings are identical to their Windows counterparts with some additional characters added in the control range.

#### Compatibility

Prior to version 4.0, `CharEncodingType` was an enum that defined only eight character encodings. The Palm OS® 4.0 definition of `CharEncodingType` is compatible with the previous definition.

## Text Manager Functions

### **TxtByteAttr**

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                            |                                     |                           |                                    |                             |                                      |                             |                        |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|-------------------------------------|---------------------------|------------------------------------|-----------------------------|--------------------------------------|-----------------------------|------------------------|
| <b>Purpose</b>              | Return the possible locations of a given byte within a multi-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <b>Declared In</b>          | <code>TextMgr.h</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                            |                                     |                           |                                    |                             |                                      |                             |                        |

| <b>Parameters</b>           | <code>-&gt; inByte</code> A byte representing all or part of a valid character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <b>Result</b>               | Returns a byte with one or more of the following bits set:<br><table><tr><td><code>byteAttrFirst</code></td><td>First byte of multi-byte character.</td></tr><tr><td><code>byteAttrLast</code></td><td>Last byte of multi-byte character.</td></tr><tr><td><code>byteAttrMiddle</code></td><td>Middle byte of multi-byte character.</td></tr><tr><td><code>byteAttrSingle</code></td><td>Single-byte character.</td></tr></table>                                                                                                                                                                                           | <code>byteAttrFirst</code> | First byte of multi-byte character. | <code>byteAttrLast</code> | Last byte of multi-byte character. | <code>byteAttrMiddle</code> | Middle byte of multi-byte character. | <code>byteAttrSingle</code> | Single-byte character. |
| <code>byteAttrFirst</code>  | First byte of multi-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <code>byteAttrLast</code>   | Last byte of multi-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <code>byteAttrMiddle</code> | Middle byte of multi-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <code>byteAttrSingle</code> | Single-byte character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <b>Comments</b>             | <p>If <code>inByte</code> is valid in more than one location of a character, multiple return bits are set. For example, <code>0x40</code> in the Shift JIS character encoding is valid as a single-byte character and as the low-order byte of a double-byte character. Thus, the return value for <code>TxtByteAttr(0x40)</code> on a Shift JIS system has both the <code>byteAttrSingle</code> and <code>byteAttrLast</code> bits set.</p> <p>Text manager functions that need to determine the byte positioning of a character use <code>TxtByteAttr</code> to do so. You rarely need to use this function yourself.</p> |                            |                                     |                           |                                    |                             |                                      |                             |                        |
| <b>Compatibility</b>        | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueByteAttr</code> . For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                                                                                                                              |                            |                                     |                           |                                    |                             |                                      |                             |                        |

## TxtCaselessCompare

- Purpose** Perform a case-insensitive comparison of two text buffers.
- Declared In** `TextMgr.h`
- Prototype** `Int16 TxtCaselessCompare (const Char* s1, UInt16 s1Len, UInt16* s1MatchLen, const Char* s2, UInt16 s2Len, UInt16* s2MatchLen)`
- Parameters**
- > `s1` Pointer to the first text buffer to compare.
  - > `s1Len` Length in bytes of the text pointed to by `s1`.
  - <- `s1MatchLen` Points to the offset of the first character in `s1` that determines the sort order. Pass `NULL` for this parameter if you don't need to know this number.
  - > `s2` Pointer to the second text buffer to compare.
  - > `s2Len` Length in bytes of the text pointed to by `s2`.
  - <- `s2MatchLen` Points to the offset of the first character in `s2` that determines the sort order. Pass `NULL` for this parameter if you don't need to know this number.
- Result** Returns one of the following values:
- < 0 If `s1` occurs before `s2` in alphabetical order.
  - > 0 If `s1` occurs after `s2` in alphabetical order.
  - 0 If the two substrings that were compared are equal.
- Comments** In certain character encodings (such as Shift JIS), one character may be accurately represented as either a single-byte character or a multi-byte character. `TxtCaselessCompare` accurately matches a single-byte character with its multi-byte equivalent. For this reason, the values returned in `s1MatchLen` and `s2MatchLen` are not always equal.

## Text Manager

### Text Manager Functions

---

You must make sure that the parameters `s1` and `s2` point to a the start of a valid character. That is, they must point to the first byte of a multi-byte character or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCaselessCompare`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

In Palm OS 4.0, the `TxtCaselessCompare` function terminates when it finds a null byte in the string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameters.

**See Also** [StrCaselessCompare](#), [TxtCompare](#), [StrCompare](#)

## TxtCharAttr

**Purpose** Return a character's attributes.

**Declared In** `TextMgr.h`

**Prototype** `UInt16 TxtCharAttr (WChar inChar)`

**Parameters** `-> inChar` Any valid character.

**Result** Returns a 16-bit unsigned value with any of the following bits set:

|                            |                              |
|----------------------------|------------------------------|
| <code>charAttrPrint</code> | Printable                    |
| <code>charAttrSpace</code> | Blank space, tab, or newline |
| <code>charAttrAlNum</code> | Alphanumeric                 |
| <code>charAttrAlpha</code> | Alphabetic                   |
| <code>charAttrCntrl</code> | Control character            |

|               |                                                                                                                |
|---------------|----------------------------------------------------------------------------------------------------------------|
| charAttrGraph | Character that appears on the screen; that is, is not whitespace, a control character, or a virtual character. |
| charAttrDelim | Word delimiter (whitespace or punctuation).                                                                    |

**Comments** The character passed to this function must be a valid character given the system encoding.

This function is used in the text manager's character attribute macros ([TxtCharIsAlNum](#), [TxtCharIsCntrl](#), and so on). The macros perform operations analogous to the standard C functions `isPunct`, `isPrintable`, and so on. Usually, you'd use one of these macros instead of calling `TxtCharAttr` directly.

To obtain attributes specific to a given character encoding, use [TxtCharXAttr](#).

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharAttr`. For more information, see [Chapter 75](#), "[PalmOSGlue Library](#)."

**See Also** [TxtCharIsValid](#)

## TxtCharBounds

**Purpose** Return the boundaries of a character containing the byte at a specified offset in a string.

**Declared In** `TextMgr.h`

**Prototype** `WChar TxtCharBounds (const Char* inText, UInt32 inOffset, UInt32* outStart, UInt32* outEnd)`

**Parameters**

|             |                                                                                                                                            |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| -> inText   | Pointer to the text buffer to search.                                                                                                      |
| -> inOffset | A valid offset into the buffer inText. This location may contain a byte in any position (start, middle, or end) of a multi-byte character. |

## Text Manager

### Text Manager Functions

---

`<- outStart`      Points to the starting offset of the character containing the byte at `inOffset`.

`<- outEnd`        Points to the ending offset of the character containing the byte at `inOffset`.

**Result**        Returns the character located between the offsets `outStart` and `outEnd`.

**Comments**     Use this function to determine the boundaries of a character in a string or text buffer.

If the byte at `inOffset` is valid in more than one location of a character, the function must search back toward the beginning of the text buffer until it finds an unambiguous byte to determine the appropriate boundaries. For this reason, `TxtCharBounds` is often slow and should be used only where needed.

You must make sure that the parameter `inText` points to the beginning of the string. That is, if the string begins with a multi-byte character, `inText` must point to the first byte of that character; if it doesn't, results are unpredictable.

**Compatibility**    Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharBounds`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## TxtCharEncoding

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Return the minimum encoding required to represent a character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Declared In</b>   | TextMgr.h                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | CharEncodingType TxtCharEncoding (WChar inChar)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>    | -> inChar      A valid character.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Result</b>        | A <a href="#">CharEncodingType</a> value that indicates the minimum encoding required to represent inChar. If the character isn't recognizable, charEncodingUnknown is returned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Comments</b>      | <p>The minimum encoding is the encoding that takes the lowest number of bytes to represent the character. For example, if the character is a blank or a tab character, the minimum encoding is charEncodingAscii because these characters can be represented in single-byte ASCII. If the character is a ü, the minimum encoding is charEncodingISO8859_1.</p> <p>Because Palm OS only supports a single character encoding at a time, the result of this function is always logically equal to or less than the encoding used on the current system. That is, you'll only receive a return value of charEncodingISO8859_1 if you're running on a US or European system and you pass a non-ASCII character.</p> <p>Use this function for informational purposes only. Your code should not assume that the character encoding returned by this function is the Palm OS system character encoding. (Instead use FtrGet as shown in the <a href="#">TxtCharXAttr</a> function description.)</p> <p>Use <a href="#">TxtMaxEncoding</a> to determine the order of encodings.</p> |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Text Manager

### Text Manager Functions

---

`TxtGlueCharEncoding`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtStrEncoding](#), [TxtMaxEncoding](#)

## TxtCharIsAlNum

**Purpose** Macro that indicates if the character is alphanumeric.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsAlNum (ch)`

**Parameters** `-> ch` A valid character.

**Result** Returns `true` if the character is a letter in an alphabet or a numeric digit, `false` otherwise.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsAlNum`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtCharIsDigit](#), [TxtCharIsAlpha](#)

## TxtCharIsAlpha

**Purpose** Macro that indicates if a character is a letter in an alphabet.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsAlpha (ch)`

**Parameters** `-> ch` A valid character.

**Result** Returns `true` if the character is a letter in an alphabet, `false` otherwise.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsAlpha`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtCharIsAlNum](#), [TxtCharIsLower](#), [TxtCharIsUpper](#)

## **TxtCharIsCntrl**

**Purpose** Macro that indicates if a character is a control character.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsCntrl (ch)`

**Parameters** `-> ch` A valid character.

**Result** Returns `true` if the character is a non-printable character, such as the bell character or a carriage return; `false` otherwise.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsCntrl`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

## **TxtCharIsDelim**

**Purpose** Macro that indicates if a character is a delimiter.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsDelim (ch)`

**Parameters** `-> ch` A valid character.

**Result** Returns `true` if the character is a word delimiter (whitespace or punctuation), `false` otherwise.

## Text Manager

### Text Manager Functions

---

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsDelim`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## TxtCharIsDigit

**Purpose** Macro that indicates if the character is a decimal digit.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsDigit (ch)`

**Parameters** `-> ch` A valid character.

**Result** Returns `true` if the character is 0 through 9, `false` otherwise.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsDigit`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtCharIsAlNum](#), [TxtCharIsHex](#)

## TxtCharIsGraph

**Purpose** Macro that indicates if a character is a graphic character.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsGraph (ch)`

**Parameters** `-> ch` A valid character.

**Result** Returns `true` if the character is a graphic character, `false` otherwise.

**Comments** A graphic character is any character visible on the screen, in other words, letters, digits, and punctuation marks. A blank space is not a graphic character because it is not visible.

This macro differs from [TxtCharIsPrint](#) in that it returns `false` if the character is whitespace. `TxtCharIsPrint` returns `true` if the character is whitespace.

**Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsGraph`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## **TxtCharIsHardKey**

**Purpose** Macro that returns `true` if the character is one of the hard keys on the device.

**Declared In** `TxtMgr.h`

**Prototype** `TxtCharIsHardKey (m, ch)`

**Parameters**

- > m The modifier keys from the [keyDownEvent](#).
- > ch The character from the `keyDownEvent`.

**Result** `true` if the character is one of the built-in hard keys on the device, `false` otherwise.

**Compatibility** Valid only if [International Feature Set](#) is present.

**See Also** [ChrIsHardKey](#)

## **TxtCharIsHex**

## **TxtCharIsPunct**

- Purpose** Macro that indicates if a character is a punctuation mark.
- Declared In** `TxtMgr.h`
- Prototype** `TxtCharIsPunct (ch)`
- Parameters** `-> ch` A valid character.
- Result** Returns `true` if the character is a punctuation mark, `false` otherwise.
- Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsPunct`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## **TxtCharIsSpace**

- Purpose** Macro that indicates if a character is a whitespace character.
- Declared In** `TxtMgr.h`
- Prototype** `TxtCharIsSpace (ch)`
- Parameters** `-> ch` A valid character.
- Result** Returns `true` if the character is whitespace such as a blank space, tab, or newline; `false` otherwise.
- Compatibility** Valid only if [International Feature Set](#) is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharIsSpace`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## TxtCharIsUpper

|                      |                                                                                                                                                                                                                                                                                                          |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Macro that indicates if a character is an uppercase letter.                                                                                                                                                                                                                                              |
| <b>Declared In</b>   | <code>TxtMgr.h</code>                                                                                                                                                                                                                                                                                    |
| <b>Prototype</b>     | <code>TxtCharIsUpper (ch)</code>                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>    | -> <code>ch</code> A valid character.                                                                                                                                                                                                                                                                    |
| <b>Result</b>        | Returns <code>true</code> if the character is an uppercase letter, <code>false</code> otherwise.                                                                                                                                                                                                         |
| <b>Compatibility</b> | Valid only if <a href="#">International Feature Set</a> is present. To use this macro in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call <code>TxtGlueCharIsUpper</code> . For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a> |
| <b>See Also</b>      | <a href="#">TxtCharIsAlpha</a> , <a href="#">TxtCharIsLower</a>                                                                                                                                                                                                                                          |

## TxtCharIsValid

|                      |                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Purpose</b>       | Determine whether a character is valid character given the Palm OS character encoding.                                                                    |
| <b>Declared In</b>   | <code>TextMgr.h</code>                                                                                                                                    |
| <b>Prototype</b>     | <code>Boolean TxtCharIsValid (WChar inChar)</code>                                                                                                        |
| <b>Parameters</b>    | -> <code>inChar</code> A character.                                                                                                                       |
| <b>Result</b>        | Returns <code>true</code> if <code>inChar</code> is a valid character; <code>false</code> if <code>inChar</code> is not a valid character.                |
| <b>Compatibility</b> | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, |

## Text Manager

### Text Manager Functions

---

link with the PalmOSGlue library and call `TxtGlueCharIsValid`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtCharAttr](#), [TxtCharIsPrint](#)

## TxtCharSize

**Purpose** Return the number of bytes required to store the character in a string.

**Declared In** `TextMgr.h`

**Prototype** `UInt16 TxtCharSize (WChar inChar)`

**Parameters** `-> inChar` A valid character.

**Result** The number of bytes required to store the character in a string.

**Comments** Although character variables are always two-byte long `WChar` values, in some character encodings such as Shift-JIS, characters in strings are represented by a mix of one or more bytes per character. If the character can be represented by a single byte (its high-order byte is 0), it is stored in a string as a single-byte character.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharSize`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

**See Also** [TxtCharBounds](#)

## TxtCharWidth

- Purpose** Return the width required to display the specified character in the current font. If the specified character does not exist within the current font, the missing character symbol is substituted.
- Declared In** `TextMgr.h`
- Prototype** `Int16 TxtCharWidth (WChar inChar)`
- Parameters** `-> inChar` A valid character.
- Result** Returns the width of the specified character (in pixels).
- Comments** Use [FntWCharWidth](#) or `FntGlueWCharWidth` instead of this routine.
- Compatibility** Implemented only if [International Feature Set](#) is present.

## TxtCharXAttr

- Purpose** Return the extended attribute bits for a character.
- Declared In** `TextMgr.h`
- Prototype** `UInt16 TxtCharXAttr (WChar inChar)`
- Parameters** `-> inChar` A valid character.
- Result** Returns an unsigned 16-bit value with one or more extended attribute bits set. For specific return values, look in the header files that are specific to certain character encodings (`CharLatin.h` or `CharShiftJIS.h`).
- Comments** To interpret the results, you must know the character encoding being used. Use [FtrGet](#) with `sysFtrNumEncoding` as the feature number to determine the character encoding. This returns one of the [CharEncodingType](#) values. For example:

## Text Manager

### Text Manager Functions

---

```
WChar ch;
UInt16 attr;
UInt32 encoding;
...
attr = TxtCharXAttr(ch);
if (FtrGet(sysFtrCreator, sysFtrNumEncoding,
    &encoding) != errNone)
    encoding = charEncodingPalmLatin;
if (encoding == charEncodingUTF8) {
}
```

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueCharXAttr`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtCharAttr](#)

## TxtCompare

**Purpose** Performs a case-sensitive comparison of all or part of two text buffers.

**Declared In** `TextMgr.h`

**Prototype** `Int16 TxtCompare (const Char* s1, UInt16 s1Len, UInt16* s1MatchLen, const Char* s2, UInt16 s2Len, UInt16* s2MatchLen)`

**Parameters**

|               |                                                                                                                                                       |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> s1         | Pointer to the first text buffer to compare.                                                                                                          |
| -> s1Len      | The length in bytes of the text pointed to by s1.                                                                                                     |
| <- s1MatchLen | Points to the offset of the first character in s1 that determines the sort order. Pass NULL for this parameter if you don't need to know this number. |
| -> s2         | Pointer to the second text buffer to compare.                                                                                                         |
| -> s2Len      | The length in bytes of the text pointed to by s2.                                                                                                     |

<- s2MatchLen Points to the offset of the first character in s2 that determines the sort order. Pass NULL for this parameter if you don't need to know this number.

**Result** Returns one of the following values:

< 0 If s1 occurs before s2 in alphabetical order.

> 0 If s1 occurs after s2 in alphabetical order.

0 If the two substrings that were compared are equal.

**Comments** This function performs a case-sensitive comparison. If you want to perform a case-insensitive comparison, use [TxtCaselessCompare](#).

The s1MatchLen and s2MatchLen parameters are not as useful for the TxtCompare function as they are for the TxtCaselessCompare function because TxtCompare implements a multi-pass sort algorithm. (See the Compatibility section below for further details.) For example, comparing the string "celery" with the string "Cauliflower" returns a positive value to indicate that "celery" sorts after "Cauliflower," and it returns a match length of 1 to indicate that the second letter determines the sort order ("e" comes after "a"). However, because TxtCompare ultimately does a case-sensitive comparison, comparing the string "c" to the string "C" produces a negative result and a match length of 0.

In certain character encodings (such as Shift JIS), one character may be accurately represented as either a single-byte character or a multi-byte character. TxtCompare accurately matches a single-byte character with its multi-byte equivalent. For this reason, the values returned in s1MatchLen and s2MatchLen are not always equal.

You must make sure that the parameters s1 and s2 point to the start of a valid character. That is, they must point to the first byte of a multi-byte character or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS,

## Text Manager

### *Text Manager Functions*

---

link with the PalmOSGlue library and call `TxtGlueCompare`. For more information, see [Chapter 75, “PalmOSGlue Library.”](#)

Prior to Palm OS 4.0, `TxtCompare` and `StrCompare` only performed one level of comparison and returned as soon as they found two unequal characters. For example, if you compared the string “celery” with the string “Cauliflower,” both functions returned a value indicating that “celery” should appear before “Cauliflower” because they sorted “c” before “C.”

In Palm OS 4.0, `StrCompare` calls `TxtCompare`, and `TxtCompare` performs a comparison using up to six comparison tables for sorting with increasing precision. As a result, in Palm OS 4.0 and higher, `TxtCompare` sorts “Cauliflower” before “celery.” The `TxtGlueCompare` function uses a two-pass sort on pre-4.0 devices, which will also sort “Cauliflower” before “celery.”

Palm OS 4.0 sorting of Shift-JIS characters attempts to duplicate the sorting algorithm described by the JIS standard.

In Palm OS 4.0, the `TxtCompare` function terminates when it finds a null byte in the string. In earlier releases, it terminated only when it reached the ending byte specified by the length parameters.

Upon return, contains the number of bytes successfully processed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                  |                                                                                                                                     |              |                                                                                                                                                                                                   |             |                                                                                                                                                                                                                                                          |                |                                                                                                                                                        |                |                                                                                                                               |
| -> srcEncoding     | The character encoding that srcTextP currently uses. This should be one of the <a href="#">Character Encoding Constants</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                  |                                                                                                                                     |              |                                                                                                                                                                                                   |             |                                                                                                                                                                                                                                                          |                |                                                                                                                                                        |                |                                                                                                                               |

## Text Manager

### Text Manager Functions

---

- `<- dstTextP` A pointer to the destination text buffer or `NULL`. This should always point to the location where `TxtConvertEncoding` can begin writing.
- `<-> ioDstBytes` A pointer to the length in bytes of `dstTextP`. Upon return, contains the number of bytes required to represent `srcTextP` in the new encoding.
- `-> dstEncoding` The character encoding to which to convert `srcTextP`. This should be one of the [Character Encoding Constants](#).
- `-> substitutionStr` A string that should be used to substitute any invalid or inconvertible characters that occur in `srcTextP`. This string must already be in the destination encoding. If `NULL`, the function immediately returns when an invalid character is encountered.
- `-> substitutionLen` The number of bytes in `substitutionStr`, not including the terminating null byte.

**Result** Returns `errNone` upon success or one of the following if an error occurs:

- `txtErrConvertOverflow`  
The destination buffer is not large enough to contain the converted text.
- `txtErrConvertUnderflow`  
The end of the source buffer contains a partial character.
- `txtErrNoCharMapping`  
The device does not contain a mapping between the source and destination encodings for at least one of the characters in `srcTextP`.

`txtErrUnknownEncoding`

One of the specified encodings is not valid. Currently, both the source and destination encodings must match either the device's encoding or one of the Unicode character encodings.

**Comments** This function converts `ioSrcBytes` of text in `srcTextP` from the `srcEncoding` to the `dstEncoding` character encoding and returns the result in `dstTextP`.

Currently, the focus of `TxtConvertEncoding` is to convert between Unicode-encoded text and the device's character encoding. For this reason, `TxtConvertEncoding` can only handle conversions between the device's encoding and one of UTF-8, UCS-2, UTF-16LE, or UTF-16BE. If you specify any other character encoding for either the source or the destination buffer, the error code `txtErrUnknownEncoding` is returned.

You can retrieve the device's encoding using the following function:

```
FtrGet(sysFtrCreator, sysFtrNumEncoding,  
      &encoding)
```

If you're converting text that was received from the Internet, the encoding's name is passed along with the text data. Use the [TxtNameToEncoding](#) function to convert the name to a `CharEncodingType` value.

The `dstTextP` buffer must be large enough to hold the result of converting `srcTextP` to the specified encoding. You can pass `NULL` for the `dstTextP` parameter to determine the required length of the buffer before actually doing the conversion. (The required length is returned in `ioDstBytes`.)

If the function encounters an inconvertible character in the source text, it puts `substitutionStr` in the destination buffer in that character's place and continues the conversion. When the conversion is complete, it returns `txtErrNoCharMapping` to indicate that an error occurred. If `substitutionStr` is `NULL`, the function stops the conversion and immediately returns `txtErrNoCharMapping`. `ioSrcBytes` is set to the offset of the inconvertible character, `dstTextP` contains the converted string up

## Text Manager

### Text Manager Functions

---

to that point, and `ioDstBytes` contains the size of the converted text. You can examine the character at `ioSrcBytes` and choose to move past it and continue the conversion. Follow the rules for making repeated calls to `TxtConvertEncoding` as described in the next paragraph.

You can make repeated calls to `TxtConvertEncoding` in a loop if you only want to convert part of the input buffer at a time. When you make repeated calls to this function, the first call should use `true` for `newConversion`, and `srcTextP` should point to the start of the text buffer. All subsequent calls should use the following values:

|                                   |                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>newConversion</code>        | <code>false</code> .                                                                                                                                                                                                                                                                                                                        |
| <code>ioStateP</code>             | The same data that was returned by the previous invocation.                                                                                                                                                                                                                                                                                 |
| <code>srcTextP</code>             | The location where this call should begin converting. Typically, this would be the previous <code>srcTextP</code> plus the number of bytes returned in <code>ioSrcBytes</code> .<br><br>If you are skipping over an unconvertible character, <code>srcTextP</code> must point to the character after that location.                         |
| <code>&lt;-&gt; ioSrcBytes</code> | The number of bytes that this function call should convert.                                                                                                                                                                                                                                                                                 |
| <code>dstTextP</code>             | A pointer to a location where this function can begin writing the converted string. You might choose to have each function call write to a different destination buffer. To have successive calls write to the same buffer, pass the previous <code>dstTextP</code> plus the number of bytes returned in <code>ioDstBytes</code> each time. |
| <code>ioDstBytes</code>           | The number of bytes available for output in the <code>dstTextP</code> buffer. In other words, the number of bytes remaining.                                                                                                                                                                                                                |

**Compatibility**    Implemented only if [4.0 New Feature Set](#) is present.

## TxtEncodingName

|                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                   |          |                       |            |                    |                                |                      |           |                   |             |                  |       |     |                           |

| encodingNameUTF8      | UTF-8                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                   |          |                       |            |                    |                                |                      |           |                   |             |                  |       |     |                           |
| " "                   | The encoding is not known                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                   |          |                       |            |                    |                                |                      |           |                   |             |                  |       |     |                           |
| <b>Comments</b>       | Use this function to obtain the official name of the character encoding, suitable to pass to an Internet application or any other application that requires the character encoding's name to be passed along with the data.                                                                                                                                                                                                                                                                                                                                    |                   |          |                       |            |                    |                                |                      |           |                   |             |                  |       |     |                           |
| <b>Compatibility</b>  | Implemented only if <a href="#">International Feature Set</a> is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call TxtGlueEncodingName. For more information, see <a href="#">Chapter 75, "PalmOSGlue Library."</a>                                                                                                                                                                                                                                                           |                   |          |                       |            |                    |                                |                      |           |                   |             |                  |       |     |                           |
| <b>See Also</b>       | <a href="#">TxtNameToEncoding</a>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                   |          |                       |            |                    |                                |                      |           |                   |             |                  |       |     |                           |

## **TxtFindString**

- Purpose** Perform a case-insensitive search for a string in another string.
- Declared In** `TextMgr.h`
- Prototype** `Boolean TxtFindString (const Char* inSourceStr, const Char* inTargetStr, UInt32* outPos, UInt16* outLength)`
- Parameters**
- > `inSourceStr` Pointer to the string to be searched.
  - > `inTargetStr` Prepared version of the string to be found. This string should either be passed directly from the `strToFind` field in the [sysAppLaunchCmdFind](#) launch code's parameter block or it should be prepared using the PalmOSGlue function [TxtGluePrepFindString](#).
  - <- `outPos` Pointer to the offset of the match in `inSourceStr`.
  - <- `outLength` Pointer to the length in bytes of the matching text.
- Result** Returns `true` if the function finds `inTargetStr` within `inSourceStr`; `false` otherwise.
- If found, the values pointed to by the `outPos` and `outLength` parameters are set to the starting offset and the length of the matching text. If not found, the values pointed to by `outPos` and `outLength` are set to 0.
- The search that `TxtFindString` performs is locale-dependent. On most ROMs with Latin-based encodings, `TxtFindString` returns `true` only if the string is at the beginning of a word. On Shift-JIS encoded ROMs, `TxtFindString` returns `true` if the string is located anywhere in the word.
- Comments** Use this function instead of [FindStrInStr](#) to support the global system find facility. This function contains an extra parameter,

outLength, to specify the length of the text that matched. Pass this value to [FindSaveMatch](#) in the appCustom parameter. Then when your application receives sysAppLaunchCmdGoTo, the matchCustom field contains the length of the matching text. You use the length of matching text to highlight the match within the selected record.

You must make sure that the parameters inSourceStr and inTargetStr point to the start of a valid character. That is, they must point to the first byte of a multi-byte character, or they must point to a single-byte character; if they don't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call [TxtGlueFindString](#). For more information, see [Chapter 75, "PalmOSGlue Library."](#)

## TxtGetChar

**Purpose** Retrieve the character starting at the specified offset within a text buffer.

**Declared In** TextMgr.h

**Prototype** WChar TxtGetChar (const Char\* inText,  
UInt32 inOffset)

**Parameters**

|             |                                                                                               |
|-------------|-----------------------------------------------------------------------------------------------|
| -> inText   | Pointer to the text buffer to be searched.                                                    |
| -> inOffset | A valid offset into the buffer inText. This offset must point to an inter-character boundary. |

**Result** Returns the character at inOffset in inText.

**Comments** You must make sure that the parameter inText points to the start of a valid character. That is, it must point to the first byte of a multi-

## Text Manager

### Text Manager Functions

---

byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetNextChar](#), [TxtSetNextChar](#)

## TxtGetNextChar

**Purpose** Retrieve the character starting at the specified offset within a text buffer.

**Declared In** `TextMgr.h`

**Prototype** `UInt16 TxtGetNextChar (const Char* inText, UInt32 inOffset, WChar* outChar)`

**Parameters**

|                          |                                                                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>inText</code>   | Pointer to the text buffer to be searched.                                                                                             |
| -> <code>inOffset</code> | A valid offset into the buffer <code>inText</code> . This offset must point to an inter-character boundary.                            |
| <- <code>outChar</code>  | The character at <code>inOffset</code> in <code>inText</code> . Pass NULL for this parameter if you don't need the character returned. |

**Result** Returns the size in bytes of the character at `inOffset`. If `outChar` is not NULL upon entry, it points to the character at `inOffset` upon return.

**Comments** You can use this function to iterate through a text buffer character-by-character in this way:

```
UInt16 i = 0;
WChar ch;
while (i < bufferLength) {
```

```
        i += TxtGetNextChar(buffer, i, &ch);  
        //do something with ch.  
    }
```

You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetNextChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)

**See Also** [TxtGetChar](#), [TxtGetPreviousChar](#), [TxtSetNextChar](#)

## TxtGetPreviousChar

**Purpose** Retrieve the character before the specified offset within a text buffer.

**Declared In** `TextMgr.h`

**Prototype** `UInt16 TxtGetPreviousChar (const Char* inText, UInt32 inOffset, WChar* outChar)`

**Parameters**

|                          |                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| -> <code>inText</code>   | Pointer to the text buffer to be searched.                                                                                                                |
| -> <code>inOffset</code> | A valid offset into the buffer <code>inText</code> . This offset must point to an inter-character boundary.                                               |
| <- <code>outChar</code>  | The character immediately preceding <code>inOffset</code> in <code>inText</code> . Pass NULL for this parameter if you don't need the character returned. |

**Result** Returns the size in bytes of the character preceding `inOffset` in `inText`. If `outChar` is not NULL upon entry, then it points to the character preceding `inOffset` upon return. Returns 0 if `inOffset` is at the start of the buffer (that is, `inOffset` is 0).

## Text Manager

### Text Manager Functions

---

**Comments** You can use this function to iterate through a text buffer character-by-character in this way:

```
WChar ch;
/* Find the start of the character containing
the last byte. */
TxtCharBounds (buffer, bufferLength - 1,
&start, &end);
i = start;
while (i > 0) {
    i -= TxtGetPreviousChar(buffer, i, &ch);
    //do something with ch.
}
```

This function is often slower to use than [TxtGetNextChar](#) because it must determine the appropriate character boundaries if the byte immediately before the offset is valid in more than one location (start, middle, or end) of a multi-byte character. To do this, it must work backwards toward the beginning of the string until it finds an unambiguous byte.

You must make sure that the parameter `inText` points to the start of a valid character. That is, it must point to the first byte of a multi-byte character or it must point to a single-byte character; if it doesn't, results are unpredictable.

**Compatibility** Implemented only if [International Feature Set](#) is present. To use this function in code intended to be run on earlier versions of Palm OS, link with the PalmOSGlue library and call `TxtGlueGetPreviousChar`. For more information, see [Chapter 75, "PalmOSGlue Library."](#)
